Ans. I couldn't say, sir, who it was put on by.

Cr.-int. 4. Was it the same brake spoken of as being put on by M'r Sayles, by the previous witness, M'r Lynch?

Ans. Yes, sir.

EDWIN A. THOMAS.

Examination taken, reduced to writing, and by the witness subscribed and sworn to this 19th day of September, 1872, before me.

FRANCIS A. DANIELS,
U. S. Commissioner.

1242 OLIVER A. LOCKWOOD, of Cranston, in the county of Providence and State of Rhode Island, having been duly sworn according to law, testifies and says as follows:

Direct examination by M'r Cozzens:

Int. What is your name, age, residence and occupation?

Ans. Oliver A. Lockwood; age, forty-seven; live in Cranston. I am a brakeman on the Providence and Worcester Railroad.

Int. 2. How long have you been brakeman on that road?

Ans. Eight years.

Int. 3. During that time what kind of trains have you braked?

Ans. Passenger trains mostly. A year and a half I braked a freight train, and the rest of the time passenger trains.

Int. 4. Do you remember recently running as brakeman on a passenger train on that road in which there was a car having on it a brake called the Springfield brake?

Ans. I ran a car last spring that I don't know what they called the brake, but it didn't work well. On one end of the car was two chains around the windlasses, and on the other end was one chain around the windlass. You would get about one turn on the brake and it would fetch up tight, and you couldn't turn it either way; and the car would go on the same as though there was no brake. Sometimes it would hold a little—nothing to be safe with.

Int. 5. Did you yourself brake on that car while that brake was on it?

Ans. I braked on it every other day.

Int. 6. For about how long?

1243 Ans. I don't recollect; because we brakemen made such a fuss about it they were obliged to take it away.

Int. 7. Was it some little time?

Ans. A few days—not many days. I didn't pay much attention. I know we made such a fuss they took it away.

Int. 8. You say above, "and you couldn't turn it either way;" please state more fully what you mean by this.

A. Well, what I mean to say is, I couldn't turn it any further. That's all. I didn't mean to say you couldn't turn it back. But you couldn't turn it any further.

Cross-examination waived.

OLIVER A. LOCKWOOD.

Examination taken, reduced to writing, and by the witness sworn to before me this 19th day of September, 1872.

FRANCIS A. DANIELS,
U. S. Commissioner.

Olney L. Smith recalled.

Direct examination by M'r Cozzens:

Int. 1. You were asked the other day about the length of time that the Tanner brake was continued in general use on the Providence and Worcester Railroad. Will you please state whether, since your examination then, you have looked into the matter of the length of time said brake was continued in use; and, if you have, please state about

1244 when you now find that it first went into use on that road, and about how long it continued in general use there?

Ans. I find the Turner license deed, under which the Tanner brake was put on to that road, was purchased in November, 1851. The brake was immediately put on after the purchase, and used until they purchased the Hodge in 1867.

Int. 2. Did you take off the Tanner brakes immediately on your purchasing the Hodge license?

Ans. I suppose that the order was given to take off the Tanner as soon as the company had purchased their license; and I did as soon as I got orders from the superintendent.

Int. 3. What I want to know is—were Tanner brakes continued in use on the Providence and Worcester road for some considerable time after you first began to put the Hodge brakes on the road?

Ans. Well, they might have been some time. I couldn't state how many days or weeks. We had twenty cars, I think—sixteen passengers, first class, and four second class, at that time. I should say that we took off the Tanner as fast as we could make irons to take their place, and changed them right along.

Int. 4. Was there a period during which there were both Tanner brakes and Hodge brakes running on the passenger cars of the road, before you got the Tanner brakes all off?

Ans. Oh, yes, I presume there were. Oh, yes, we couldn't change sixteen or twenty cars. We had only a few men and wouldn't change them, perhaps, in sixty days.

Int. 5. During this time that both Tanner brakes and Hodge brakes were running on the passenger cars of said road, please state what, if any, difference there was in the effect of the two kinds of brakes as to holding the cars, and general efficiency, when they were both in order?

1245 Ans. I have no recollection of any particular expressions made by the brakemen on the road stating any difference or dissatisfaction with one more than the other. Both out of order they would complain of; and both in order, you would hear no more of one than the other. All satisfactory, both the Tanner and the Hodge.

Int. 6. Will you please state the date when the Tanner brake was recently put on to the Providence and Worcester road in the form desired by M'r Sayles, the complainant in this case?

Ans. March 20, 1872.

Int. 7. How long was it continued on the road in that form at that time?

Ans. Until April 4, 1872.

Cross examination waved.

OLNEY L. SMITH.

Examination taken, reduced to writing, and by the witness subscribed and sworn to this 19th day of September, 1872, before me.

FRANCIS A. DANIELS,
U. S. Commissioner.

WILLIAM D. HILTON, of the city and county of Providence, in the State of Rhode Island, having been duly sworn according to law, testifies and says as follows:

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

Ans. William D. Hilton; age, thirty-nine; residence, city of Providence. I am superintendent of the Providence and Worcester Railroad.

1246 Int. 2. How long have you been superintendent of that road?

Ans. Six years.

Int. 3. Will you please state the circumstances under which the brakes called the Springfield brake and the Tanner brake came to be put upon the cars on the Providence and Worcester Railroad last winter?

Ans. I was requested by M'r S. M. Whipple to allow the two brakes to be put upon cars of our road to test the relative value of the two brakes.

Int. 4. Did you order the Springfield brake to be taken off of the car, and, if so, why did you do it?

Ans. I ordered the brakes taken off the car. I had so many complaints from the brakemen as to the operation of it that I ordered them taken off.

Int. 5. Will you please state how the Tanner brake came to be put upon the car on said road the second time?

Ans. I believe it was at that time I met M'r Sayles for the first time. We had some discussion as to the values of the different brakes in use, and I denounced them, I think, somewhat unsparingly, and he contended that the Tanner brake was as good a brake as was in use, if properly put on. The result of the discussion was that I allowed him to put one on the road in the manner that he stated to be the right way.

Int. 6. About how long did the Tanner brake, as M'r Sayles wished it put on, continue on the road?

Ans. I should say rising two weeks; between two and three weeks.

Int. 7. At the end of that time did you order it taken off; if so, why?

Ans. I did. I found there was considerable feeling existing that we should have ordered the other brakes off and allowed another brake to be put on and used, and to compromise the matter I ordered that brake off, so as to make it fair on both sides.

Int. 8. You say a feeling existed; a feeling with whom?

1247 A. I had, I think, a conversation with M'r S. M. Whipple on the matter. His manner—I wouldn't say that it was one of anger, or anything of that kind—but he rather felt that I had not treated them impartially in ordering his brakes off, and then allowing this other to be put on. He didn't demand of me to take this one off, but I did it of my own volition.

Int. 9. So as to be as fair to one side as the other?

Ans. Yes, sir; that was my object.

Int. 10. While the Tanner brake was on your road was there any fault found with it?

Ans. The second time?

Int. 11. Any time?

Ans. I couldn't say that there was specifically any fault.

Cross-examination waived.

WILLIAM D. HILTON.

Examination taken, reduced to writing, and by the witness sworn to, this 19th day of September, A. D. 1872, before me.

FRANCIS A. DANIELS,
U. S. Commissioner.

MARCUS L. BRAMAN recalled.

Direct examination by M'r Cozzens:

Int. 1. Have you a correction to make in the testimony given by you on September 10, 1872, in this case; if so, what is it?

Ans. Yes, sir; I came up here this morning to make the correction. I couldn't find M'r Sayles. This testimony I gave here the other day concerning that accident on the road, I have found out by talking with my wife and dates I have in my house that I was mistaken;
1248 that it took place on another train instead of the train I spoke of. My brother—come to talk with my wife and look at receipts I have in the house—left in the fall of 1871 instead of the spring of 1872. I made a large mistake in the dates. I testified it was in the spring; but, instead of that, it was in the fall that my brother left.

Cross-examination by M'r Whipple:

Cr.-int. 1. What was the accident testified to in your previous evidence which you now wish to correct?

Ans. I spoke of some cars being jammed up in the depot.

Cr.-int. 2. Please repeat the accident you testified to which you wish to correct.

Ans. The idea—it was in my head at the time I made the statement—is the accident that happened on the Lower Falls train my brother run on.

Cr.-in. 3. Do you mean the accident of smashing down the platforms referred to in your testimony?

Ans. Yes; I mean at the time the Newton Lower Falls train was switched and we had a smash-up, at the time my brother was turned off.

Cr.-int. 4. Have you seen your brother since you gave evidence here?

Ans. No, sir.

Cr.-int. 5. When were you first reminded of the mistake in your evidence in reference to the accident?

Ans. Well, it was when I talked with my wife. I can't tell you the day it was.

Cr.-int. 6. Did you go and hunt up M'r Sayles in order to make this correction, or did he seek you out?

Ans. No, sir; he has not seeked me out. I came up here and thought I would see him and state the facts as soon as I saw him.

1249 Cr.-int. 7. How did you know he was to be seen here to-day?

Ans. I didn't know he was to be seen here to-day, but I thought I would look and see.

Cr.-int. 8. What made you suppose he would be here to-day, having got through the evidence on the tenth?

Ans. Well, I didn't know that he would be here; but, at the same time, I thought I would make inquiries at the hotel where he stopped, and see if he was here.

Cr.-int. 9. What hotel did he stop at when he was here?

Ans. The Central.

Cr.-int. 10. What hotel did you go to find him this morning?

Ans. The Central Hotel, sir.

Cr.-int. 11. Did he stop at the same hotel this time as he did when he was here on the tenth?

Ans. They told me he did.

Cr.-int. 12. Who told you?

Ans. The porter in the hotel.

Cr.-int. 13. Said he stopped there on the tenth, and stopped there last night?

Ans. No, sir; you are answering one question and asking another.

Cr.-int. 14. Did the porter tell you he stopped there on the tenth?

Ans. No, sir; I knew that.

Cr.-int. 15. Did you learn from the porter that he stopped there also last night?

Ans. Yes, sir.

Cr.-int. 16. On looking over your evidence since you gave it on the tenth, do you think there are any other corrections you ought to make?

Ans. No, sir; not that I know of.

Cr.-int. 17. Have you thought it over since you gave it?

Ans. Well, yes; I think I have.

1250 Cr.-int. 18. In thinking it over, didn't you come to the conclusion that you had really stated to M'r Whipple that you wanted no better brake than the old Springfield on the car No. 124 on the Boston and Albany Railroad?

Ans. No, sir; I never stated that.

Cr.-int. 19. Didn't you frequently volunteer such statements to M'r Whipple when he appeared on that train—on that car?

Ans. No, sir; I never did.

Cr.-int. 20. Do you think there is another brakeman on that train that would corroborate you in any such statement as you have made in reference to the use of the Springfield brake on that car—No. 124?

Ans. Yes, sir.

Cr.-int. 21. Who? Please give us his name.

Ans. Well, there is one man by the name of Stafford.

Cr.-int. 22. Is he now running on the train?

Ans. The same train? Yes, sir.

Cr.-int. 23. Does he operate the brake on No. 124?

Ans. No; I think not.

Cr.-int. 24. What part of the train does he run on?

Ans. I think he runs forward—on the smoking car.

Cr.-int. 25. Between what points?

Ans. Between Boston and Springfield.

Cr.-int. 26. Were you aware at the time 123 and 124 were run in that train—one having the Tanner brake on and the other the Springfield—that both were wearing out iron, one against the other?

Ans. That is what was told me.

Cr.-int. 27. Did you apply the power as faithfully to one car as to the other, when you had it in the rear of the train?

Ans. Yes, sir.

1251 Cr.-int. 28. And yet you say that the Tanner brake held the train as well as a brake ought to, and 124 didn't hold the train at all. Is that your conclusion? Didn't even take the slack of it? That is a fact, is it?

Ans. I believe I testified it didn't take the slack at all times.

Cr.-int. 29. Did it at any time take the slack as well as the Tanner brake?

Ans. No, sir; it did not.

Cr.-int. 30. Were there times when it wouldn't take the slack?

Ans. Yes.

Cr.-int. 31. Was there ever a time when the Tanner brake wouldn't do the same?

Ans. Not that I ever see, when the Tanner brake was in perfect order.

Cr.-int. 32. Was it always in perfect order?

Ans. No, sir. Any brake is liable to be out of order.

Cr.-int. 33. May not the Springfield brake have been out of order when it didn't take the slack of the train?

Ans. It hadn't ought to be out of order week after week, right along, when we had good men to repair it.

Cr.-int. 34. Such you state to be a fact when it was run in connection with the Tanner brake, do you?

Ans. Yes, sir.

MARCUS L. BRAMAN.

Examination taken, reduced to writing, and by the witness sworn to before me this 19th day of September, 1872.

FRANCIS A. DANIELS,
U. S. Commissioner.

1252 **PELEG M. PECKHAM** recalled.

Direct examination by M'r Cozzens:

Int. 1. Will you please state in what year the Tanner brake first went into use on the cars of the Providence and Stonington Railroad?

Ans. I shouldn't want to swear to the exact time. It was either, I think, 1849 or 1850.

Int. 2. While the Tanner brake continued in use on said road, at what part of the centre lever did you make the connections to the windlasses and the truck levers?

Ans. At the ends of the centre levers.

PELEG M. PECKHAM recalled second time.

Direct examination by M'r Cozzens:

Int. 3. You stated the other day that the Tanner brake was continued in general use on the Providence and Stonington road until the company bought the Hodge brake. Was there a period, after they first commenced putting on Hodge brakes, that the Tanner brakes were continued on many of the cars before they got them all off?

Ans. Yes, sir: there was quite a period.

Int. 4. About how long should you think that period was, as near as you can recollect?

A. Well, several years.

Int. 5. State whether during this period there was any difference in the effect of the Tanner brake as compared with the Hodge brake in reference to holding the cars when the brakes were applied.

(Objected to.)

Ans. I couldn't see any, nor didn't hear of any from any of the brakemen.

1253 Cross-examination by M'r Whipple:

Cr.-int. 1. Why did you change the Tanner brake by putting on the Hodge in its place?

Ans. The reason of our changing the Tanner brake for the Hodge brake was to do away with those long rods. It made less friction by having on the Hodge brake.

Cr.-int. 2. From your knowledge of the two brakes, is there no other difference between the two than that one?

Ans. I couldn't see any.

Direct examination resumed:

Int. 6. Which do you think is the easier adjusted and kept up?

Ans. In repair, do you mean?

Int. 7. Yes; keeping adjusted?

Ans. I can't see any difference in the two brakes about that.

Cross-examination resumed:

Cr.-int. 3. Which brake will lose its adjustment quickest, the Hodge brake or the Tanner brake?

Ans. I couldn't see any difference.

Cr.-int. 4. Is the Hodge brake self-adjusting in its nature and character?

Ans. I can't see it is any more so than the other.

Cr.-int. 5. Is the Tanner brake self-adjusting in its character?

Ans. I can't see any difference in the two brakes.

PELEG M. PECKHAM.

Examination taken, reduced to writing, and by the witness sworn to this 19th day of September, 1872, before me.

FRANCIS A. DANIELS,
U. S. Commissioner.

1254 PROVIDENCE, *October* 10, 1872.

WILLIAM CAPRON called and sworn.

Direct examination by M'r Sayles, complainant, in person:

Q. 1. What is your name, age, residence, and occupation?

A. W'm Capron. I am 60 years of age; live in Providence, in the State of Rhode Island, and am a conductor on the Providence and Worcester Railroad.

Q. 2. How long have you been employed upon said road, and in what capacities?

A. Twenty-four years; and two years as baggage-master and brakeman, and the rest of the time as conductor on a passenger train.

Q. 3. While you were brakeman on said road, what kind of brakes were used on the cars?

A. For two years, while I was brakeman, we used single brakes, broke on one end of the car.

Q. 4. What kind of brakes have been used since you have been conductor on said road?

A. They were double brakes.

Q. 5. About how soon after you commenced as conductor were the double brakes applied?

A. In a few years after I commenced as conductor, but I could not state the time.

Q. 6. How did these double brakes work in stopping the trains compared with the single brakes, before the double brakes were put on?

A. The double brakes worked on both ends of the cars, and therefore they had double purchase. I consider the double brake far preferable to the single brake.

1255 Q. 7. Have you noticed any difference in the stopping of trains with the double brakes since they were first introduced on the road, down to the present time?

A. No; I never have. (I never heard it stated by the brakemen that the trains could be stopped any better with the present double brakes than with the first ones.)

(Answer objected to as hearsay.)

Cross-examined by S. M. Whipple:

Cr.-q. 8. What double brakes were first used on the Providence and Worcester road?

A. I could not answer that, as I don't know.

Cr.-q. 9. What double brakes are now used on said road?

A. I don't know.

Cr.-q. 10. Has there been a change made in double brakes upon the passenger cars on your road during the time you have been conductor?

A. I think there has. I think there was a little added to the double brake we now have; if there has been an addition I don't perceive it in braking up the trains, and I have not heard the brakemen under me make any complaint that one was better than the other, and I don't perceive but what the cars "broke up" with one just as well as the other.

Cr.-q. 11. If there is no difference in favor of the double brake you are now using, why did your company go to the expense of buying another patent and change the brakes on your road?

A. I don t know, sir; they did not consult me.

Cr.-x. 12. Do you think the company exercised bad judgment in changing the double brakes?

A. Well, I have always been taught to let well enough alone; the others always worked well, and these work well.

Cr.-q. 13. Do you say that these double brakes do not work any better than the old double brakes?

1256 A. From what I have seen, and from what I have heard from the brakemen, I should not know any difference in the stopping of the trains.

W'M CAPRON.

Subscribed and sworn to before me this 10th day of October, A. D. 1872.

D. B. POTTER,
Notary Public.

SILAS S. MOWRY called and sworn.

Direct examination by M'r Sayles, complainant, in person:

Q. 1. What is your name, age, residence, and occupation?

A. Silas S. Mowry; thirty-four yours of age; residence, Providence, State of Rhode Island; and by occupation, conductor on the Providence and Worcester Railroad.

Q. 2. Do you remember of a car being used on your train some months ago which had on a brake called the Springfield brake?

A. Yes.

Q. 3. How did that brake work?

A. It worked very poor, so much so we did not use it. My little brakeman could not set it up—could not use it—although he could set up a brake as hard as any one. I had a large brakeman also, and he found the same fault. We only had it a few days. I guess it was on there ten days, and I was glad to see it go.

Q. 4. What were these brakemen's names?

A. Leslie Crocker and George Gates.

Q. 5. Do you remember another double brake that was used on passenger car No. 26 for a while last spring; if so, how did that work?

1257 A. I do; that worked first rate. All the brakemen liked it on the train, and with half the labor that brake could be "set up" compared with the one we called the Springfield brake.

Cross-examined:

Cr.-q. 6. How did this brake you speak of compare with the brakes you now use on all your passenger-cars?

A. I liked it, from what I saw, better than these we now have on.

Cr.-q. 7. Who put on this brake you speak of?

A. M'r Sayles.

Cr.-q. 8. Do you consider the brake you are now using, compared with the one M'r Sayles put on, an inferior brake?

A. I don't think it is as good a brake as he put on; I mean by that that it is inferior.

SILAS S. MOWRY.

Sworn and subscribed to before me this 10th day of October, A. D. 1872.

D. B. POTTER,
Notary Public.

A. G. **Sherman** called and sworn.

Direct examination by M'r Sayles, complainant, in person:

Q. 1. What is your name, age, residence, and occupation?

A. A. G. Sherman; conductor on the Providence and Worcester Railroad; am thirty-eight years old, and reside in Cranston, State of R. I.

1258 Q. 2. How long have you been employed on said road, and in what capacity?

A. About 19 years. I was at first a brakeman on a passenger-train for about two years; then as baggage-master and conductor from that time to the present.

Q. 3. What kind of brakes—single or double brakes—were used while you was brakeman?

A. Double brakes.

Q. 4. How did the double brakes, used while you was brakeman, compare with the double brakes now used on said road in stopping trains?

A. I don't know as there is any difference.

Cross-examined:

Cr.-q. 5. Have you operated the brakes now on your cars as brakeman?

A. No, I have not myself.

Cr.-q. 6. How long has the present double brake been on the cars?

A. I don't know, sir.

Cr.-q. 7. Does the present double brake operate as easily and efficiently as the double brake that was on your road when you was brakeman?

A. As far as I know, it does.

Cr.-q. 8. Does it operate better?

A. I don't know as it does.

Cr.-q. 9. Why was there a change of brakes made by your company?

A. I didn't know as there was a change.

Cr.-q. 10. Do you not know that when you was brakeman they used what was called the centre-lever double brake, and after that took them all off and put on the Hodge brake which you are now using?

A. No, sir, I did not.

1259 Cr.-q. 11. If you did not how are you able to draw comparison between the two brakes?

A. Well, I haven't; I don't know any difference I say.

A. G. SHERMAN.

Subscribed and sworn to before me this 10th day of October, A. D. 1872.

D. B. POTTER,
Notary Public.

Testimony on behalf of the complainant, taken at Worcester, Mass.

U. S. circuit court, northern district of Illinois.

Thomas Sayles
vs.
The Chicago and Northwestern Railway Company.
} In equity.

Worcester, Mass., *September 17th*, 1872.

John Moran called and sworn.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. My name is John Moran; am 42 years of age; reside in Worcester; am a flagman and brakeman on the Boston & Albany Railroad.

1260 Q. 2. About how long have you been a brakeman on the Boston & Worcester, the Western, and the Boston & Albany Railroads?

A. Have been about 16 years on the Boston & Worcester road; have been about 6 years watchman and switchman on the Boston & Albany road at Worcester, and I am on the Boston & Albany road still.

Q. 3. During the time you were a brakeman on these roads what kind of trains did you brake on?

A. On passenger-trains.

Q. Did you at any time while you were on these roads brake on the Boston & New York night express train?

A. Yes, sir.

Q. 5. About what year did you first commence braking on that train, and about how long did you continue?

A. I commenced in 1851 or 1852—I don't remember exactly. I continued on the train about ten years.

Q. 6. During this time what were your duties on this train?

A. I acted as local baggage-master and brakeman.

Q. 7. While so engaged between what points on the road did you run?

A. Between Boston and Worcester.

Q. 8.. In acting as brakeman on that train, at what part of the train were you stationed to apply the brakes?

A. Coming from Boston to Worcester I was braking on the baggage-car; going to Boston I was the behind brakeman—broke on the hind car of the train.

Q. 9. During the time you were on said Boston and New York night express-train as brakeman what kind of brakes were used on that train?

A. I am not certain of the name of the brake they had on when
1261 I went on there; in a short time they got Hodge's brake on.
They took the Hodge's brake off and put a brake on they called the Springfield brake.

Q. 10. About how long, as near as you can recollect, was this Springfield brake kept on those Boston and New York express cars?

A. Some over a year—would not be positive.

Q. 11. Was it then taken off, and, if so, what brake was put on in its place?

A. It was taken off and the Hodge's brake put back in its place.

Q. 12. While this Springfield brake was on these night express cars, did you as brakeman have to apply the brake?

A. Yes, sir.

Q. 13. Please state how these Springfield brakes worked—please answer fully.

A. They worked poorly; that was the cause of them being taken off; we could not do anything with them; could not rely upon them to hold us—to stop us at stations. I had to do the switching of them at the end of the route in Boston, and sometimes I couldn't hold one car with them, and several times I bunted the posts where I had to go in the yard because I couldn't hold them, which I blame the brakes for it. Once or twice I broke a draw bar of the car because I struck the posts so hard. A good many times we run by the stations on the road a quarter of a mile because we couldn't hold the cars up—frequently we run by stations on the road on account of our brake. I don't mean a quarter of a mile; it was in the night time; I couldn't tell; it might have been more and it might have been less than a quarter of a mile, but we often ran by stations.

Q. 14. With which brake—the Hodge or the Springfield—did you have to begin the farthest back to apply the brakes when stopping at stations?

1262 A. With the Springfield brake we had to begin some ways further off than the Hodge's brake in order to stop at the stations.

Q. 15. Did the Springfield brake seem to work alike at all times, or were there differences at times in the way in which it held the trains?

A. No; sometimes it worked better than others, and on a straight line it worked better than on a curve; and it never worked to suit me.

Q. 16. Did you frequently notice when the Springfield brake was applied that the chains would overlap on the windlass shaft; and, if you did, please state what was the effect of the brake as to holding the car or train when this overlapping took place?

A. Yes; I have noticed that it overlapped, and when it overlapped the brake had no command over the car.

Q. 17. Please state whether there were frequently—while you were brakeman on the Boston and New York express car—cars from the Western Railroad, which had single brakes on them, attached to your train.

A. Yes, sir; a good many times; I don't know how often.

Q. 18. When they were attached, at what part of the train were they placed, and between what places did they run?

A. They were placed at the hind end of the train, and they ran from Springfield to Boston.

Q. 19. Did you ever apply the brakes on those single-brake cars when they were in the Boston and New York night express trains?

A. Yes, I have applied them.

Q. 20. Please state with which kind of brake—these single brakes or the Springfield brakes—you could best hold the train.

A. The single brake I preferred.

Q. 21. Which seemed to have the best effect in holding the cars?

1263 A. The single brake, which I felt confident would stop the cars when we had it on the hind end.

Q. 22. About how much of the time while the Springfield brakes were used on the Boston and New York night express trains, did you run on said trains?

A. I think I run right along regular with them, unless I was off sick once in a while.

Q. 23. When the Hodge brake was used on those night express trains how well did it work?

A. They worked good. I felt myself safe with them—and not half the labor there was with the Springfield brake.

Q. 24. Did you feel safe with the Springfield brake?

A. No; I had no confidence in the brake.

Cross-examined:

Cr.-q. 25. In what year were the Springfield brakes put on the New York express line?

A. I don't remember.

Cr.-q. 26. About what year as near as you can recollect?

A. I can't give no idea of the year.

Cr.-q. 27. At the time you were brakeman on the express line on the cars of which the Springfield brake was used, how many stops were you required to make between Boston and Worcester, and between Worcester and Boston?

A. Between Boston and Worcester we made two stops—Providence Crossing and Framingham; and between Worcester and Boston it was uncertain—we might have four or five stops; the regular stops were Framingham and Providence Crossing.

Cr.-q. 28. At what places were you liable to make extra stops other than Framingham and Providence Crossing?

A. Any station on the road we were liable to stop at; there were no specified stops. Passengers that came from New York and wanted to stop at Natick or any station—the conductor informed us and we stopped. 1264

Cr.-q. 29. Were the stations where regular stops were made or stations at which extra stops were to be made, past which you were liable to run by a quarter of a mile or more?

A. We were liable to run by any where, stopping with those brakes.

Cr.-q. 30. Did you frequently run by the station at South Framingham?

A. We ran by a good many times; can't say how many.

Cr.-q. 31. Of the twelve stops made at Framingham which were supposed to be made in one week, how many of these stops should you judge were a quarter of a mile or more?

A. I don't know of any; don't remember of any. I remember that we run by; I didn't measure the distance.

Cr.-q. 32. Do you recollect to have ever stopped at South Framingham with the Springfield brake without running by?

A. Oh, we have stopped there.

Cr.-q. 33. How often did you stop at South Framingham station where you ought to stop?

A. I don't remember.

Cr.-q. 34. Do you think you ever stopped at South Framingham station with the Springfield brake at the place you ought to stop?

A. Oh, yes.

Cr.-q. 35. How often one day with another?

A. I don't know.

Cr.-q. 36. When you stopped at the Providence Crossing did you, as a general rule, stop where you ought to, or did you, as a general rule, run on to the Crossing, with the Springfield brake?

A. Sometimes we stopped; sometimes we run on to it, and sometimes we ran across it.

1265 Cr.-q. 37. Did you ever run onto it with the Hodge brake?

A. I don't remember.

Cr.-q. 38. Do you think you ever run onto it with the Hodge brake?

A. It might be the case that all the brakes were not used, and that we ran onto it; but I don't remember any case.

Cr.-q. 39. Did you ever know a train to run by a station when you had to depend on the Hodge brake?

A. Yes.

Cr.-q. 40. Did you ever know the chain to overlap in the Hodge brake, and thus become ineffectual to hold the car?

A. I never knew it to overlap. I have known it to run off the worm.

Cr.-q. 41. How does this running off the worm affect the brake?

A. It disables the connection-rod. It is easily remedied, though.

Cr.-q. 42. What is the remedy?

A. Shortening the chain, or taking up the connection-rod.

Cr.-q. 43. Is this remedy applicable to the Springfield brake?

A. I don't know. It is a different rigging.

Cr.-q. 44. Did the chain on the Springfield brake always overlap when you attempted to apply the brake?

A. No; not always.

Cr.-q. 45. Did you consider the brake in order when the chain did overlap?

A. It was about the order we always had it.

Cr.-q. 46. When you ran by stations a quarter of a mile or more, what did you have to do?

A. When we had ladies to get out, we backed to the station, and when we had men we let them out where we were, and went on.

1266 Cr.-q. 47. On your arrival in Worcester, and also in Boston, was the train generally in on time, or behind time, when you had the Springfield brake?

A. We were pretty generally on time in our arrival in Worcester, and pretty generally on time in Boston—sometimes ten or twelve minutes late in Boston. I don't know how often.

Cr.-q. 48. When you were late in arriving in Boston, it was in consequence of having the Springfield brake, was it not?

A. I don't know.

Cr.-q. 49. Do you think having the Springfield brake had anything to do with your arriving late at Boston sometimes?

A. I don't know.

Cr.-q. 50. You speak of the Springfield brake as not holding as well on a curve as on a straight track. Where are the curves located between Worcester and Boston on which you have had occasion to brake, and thus observe the difference?

A. There are a good many curves. There is a curve going to Westboro', a curve going to Cordaville, and there is a curve going to Framingham. I braked on all those curves.

Cr.-q. 51. Any other curves on which you have had occasion to brake with the Springfield brake; if so, name them, and what was the result of your observation as to the brake holding on all of them you have named?

A. Grafton, Southboro', Wellesley, Grantville, Rice's Crossing, Charles River, Auburndale, Cottage Farm. I don't remember the result of how the brake worked on all of them.

Cr.-q. 52. Do you remember how the Springfield brake worked on any of the curves at stations named by you?

A. I can't remember just now; I can't set any time.

1267 Cr.-q. 53. Did you really observe any difference whether the train was running on a straight track or a curve in the holding of the Springfield brake?

A. Yes; the brake worked harder on a curve.

Cr.-q. 54. When it worked harder did it hold better?

A. I don't think it did.

Cr.-q. 55. Did it hold at all?

A. Sometimes it held some, and sometimes it wouldn't hold the car itself from the car ahead of it.

Cr.-q. 56. Did you ever know the Hodge brake to be in a condition that it couldn't take the slack of the train or hold the car ahead of it.

A. Yes; I have known it, when it was broken, not to take the slack.

Cr.-q. 57. Did you ever know the Springfield brake to be broken?

A. Yes; I think I have.

Cr.-q. 58. Did you ever know the Hodge brake, when it was not broken, in a condition that you couldn't take the slack of the train with it?

A. No; I don't remember.

Cr.-q. 59. Why were cars with the single brake on attached to express-line trains?

A. To accommodate the public who wanted seats.

Cr.-q. 60. You felt perfectly safe, didn't you, in running this express-train with the Springfield brake when you had a car on with the single brake?

A. I felt as if we could stop at a station when we wanted to stop.

JOHN MORAN.

Subscribed and sworn to this 17th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

1268 EDWARD A. WOOD called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation.

A. Edward A. Wood; am 28 years of age; reside in Paxton, Mass.; am at present a teamster.

Q. 2. Have you recently been employed on the Boston and Albany Railroad as a brakeman; if so, when did you leave said road?

A. I have; I left the road the first of last June—either the first day of June or the last day of May.

Q. 3. How long were you employed on said road as a brakeman?

A. One year.

Q. 4. What kind of trains did you brake on during that time?

A. Passenger-trains.

Q. 5. Was one of these passenger-trains a train which had on its cars a brake called the Springfield brake?

A. Yes, sir; after some time last winter.

Q. 6. Who was the conductor on this train that had the Springfield brakes on, and how long did you brake on said train?

A. J. B. Adams was the conductor. I broke on the train from the time it was put on till last June.

Q. 7. At what part of the train were you stationed to apply said Springfield brakes?

A. At the forward end.

Q. 8. How did said Springfield brakes work while you braked on that train?

A. They did not seem to hold, and worked hard.

Q. 9. Was there every other day, on the train that ran alternately with that train, any other kind of brake; if so, what kind?

A. Yes, sir; the Hodge brake?

1269 Q. 10. Did you brake on this train on the days when the Hodge brake was used?

A. Yes, sir.

Q. 11. With which brake—the Springfield or the Hodge—did you have to begin the farthest back when applying the brakes to stop the train?

A. The Springfield.

Q. 12. About how much further back did you have to begin to apply the Springfield brake than you did the Hodge?

A. Nearly as far again from the station.

Q. 13. State whether, on the days when the Springfield brake was used, the train would sometimes run by stations when attempting to stop?

A. It would, sometimes.

Q. 14. State what you found to be the fact, when the Springfield brake was used, as to whether it could be depended upon, as a general thing, to hold the train properly?

A. It could not.

Q. 15. State whether you ever noticed that one of the chains of the Springfield brake would sometimes overlap on the eye of the windlass-staff so that the two chains could not be pulled equally when the brake was applied?

A. I have noticed it overlap.

Q. 16. When this overlapping took place, what was the effect as to holding the car?

A. It would not hold.

Cross-examined:

Cr.-q. 17. How many cars composed the trains upon which M'r John B. Adams was conductor, and how many brakemen were allowed to operate the brakes on said trains?

1270 A. There were five cars on the train in the winter, from Springfield to Albany, and in the summer there was six. There were two brakemen allowed on the trains to operate the brakes.

Cr.-q. 18. Who acted as brakeman with you while you were on said trains?

A. Henry F. Taylor.

Cr.-q. 19. How long were the chains of the Springfield brake which wound around the brake-staff on the cars of which you operated the brakes?

A. I don't know.

Cr.-q. 20. In operating these brakes, did the hook of the rod at the end of the chain come up against the brake-staff so as to shut off the power from the wheels?

A. No, sir.

Cr.-q. 21. Was there always chain enough so that you could put your whole force on the brake and not take up all the chain?

A. Yes, sir.

Cr.-q. 22. About how many revolutions of the brake-wheel could you make before the brake was fully set?

A. I could not tell.

Cr.-q. 23. How many times do you think the chain was wound around the brake-staff in applying either the Hodge or Springfield brake?

A. I don't know, sir.

Cr.-q. 24. How many times should you judge, from observation?

A. I couldn't tell. It is some time since I used it.

Cr.-q. 25. Do you think it requires three or four revolutions of the brake-wheel to operate the brakes in question?

A. I should think about three.

Cr.-q. 26. In your judgment, did it take, as a general rule, about three revolutions to set firmly the Springfield brake?

A. I should think so. I never counted them.

1271 Cr.-q. 27. Did the Springfield brake, at any time you operated it, seem to hold the car as a car ought to be held in stopping it?

A. Sometimes it would hold.

Cr.-q. 28. Did the train ever run by a station with the Hodge brake?

A. Sometimes; but not very often.

Cr.-q. 29. When the trains with the Springfield brake on ran by, what part of the length of the train did it pass the point where it ought to stop?

A. Sometimes more, sometimes less.

Cr.-q. 30. May not the Springfield brake have been out of order at times when it allowed you to run by the station?

A. It never was, to my recollection.

Cr.-q. 31. Then, according to your recollection, it was never out of order. Is that what you mean?

A. Yes, sir; while I was brakeman; the brakes I handled.

Cr.-q. 32. Did you ever know the Hodge brake to be out of order so as to be ineffectual in stopping the trains properly?

A. No, sir.

Cr.-q. 33. Are not all brakes liable to be out of order from various causes?

A. Yes, sir.

Cr.-q. 34. But I take it, from your experience with the Springfield brake, that it was never out of order. Is that so?

A. It might have been. I might not recollect it.

Redirect:

Q. 35. You have spoken of the number of times the windlass-wheel was turned to apply the Springfield and Hodge brakes. May it have been less than three times that it was turned?

A. Yes, sir; it might have been. It is something I never counted or took any particular notice of.

1272 Recross:

Cr.-q. 36. How many turns of the windlass-wheel did you have to make when the chains overlapped, as you have stated that they did?

A. I have seen them catch on the eye the first time round. I couldn't tell how many turns after that; but in a short time I could pull it no further.

Cr.-q. 37. When you could pull it no further, was it not from the fact that there was no more chain to wind on the staff?

A. No, sir.

Cr.-q. 38. Did you take particular notice and observe that there was still more chain to wind on the staff when you could pull the chain no further?

A. I did, sir, as on several occasions I have got down on the platform and step and looked under.

Cr.-q. 39. Was the brake still on when you got down and looked under?

A. Yes, sir.

Cr.-q. 40. Had you, before looking down, wound the chain upon the staff at least twice round it in applying the brakes?

A. I should say not.

Cr.-q. 41. Do the chains of the Springfield brake wind at least once round the staff in putting the brakes firmly on?

A. Yes, sir.

Cr.-q. 42. Do they twice round?

A. I couldn't say.

Cr.-q. 43. What do you think about it?

A. I couldn't tell how many times round.

Cr.-q. 44. Do you think there would be much overlapping of the chains when the slack and wear of the brake is so small that the brake could be firmly set inside of two turns of the brake-wheel?

A. I do.

1273 Cr.-q. 45. In the overlapping of the chains, did one chain ride down upon the brake-staff and overlap the other chain?

A. No, sir; it did not.

Cr.-q. 46. Did the upper chain in any way come in contact with the lower chain?

A. Not round the brake staff.

Cr.-q. 47. In this matter of overlapping the chains, did you observe anything more than that the first link of one of them lopped down a little before the chain went direct round the windlass staff?

A. Yes, sir.

Cr.-q. 48. What more?

A. The chain would wind round and catch on the eye by one of the links.

Cr.-q. 49. Did this always happen when you tried to set up the Springfield brake?

A. No, sir; not always.

Cr.-q. 50. How did the brake hold when it did not so happen?

A. It would hold some, but not so well as the Hodge brake.

EDWARD A. WOOD.

Subscribed and sworn to this 17th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

LORENZO HARDING called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation?

A. Lorenzo Harding; am 63 years of age; reside in Worcester, Mass. I am a car builder by occupation. At present I am engaged in repairing and taking care of passenger-cars at the Foster street station for the Boston and Albany Railroad. 1274

Q. 2. How long have you been employed on the Boston and Worcester Railroad—now the Boston and Albany Railroad?

A. About 18 years; I can't state the time exactly.

Q. 3. What have been your duties on said road during that time?

A. Principally in taking care of and repairing cars, and inspecting them when running through from Springfield to Boston. Before the roads were consolidated—making the Boston and Albany road—we inspected every car that came off of the Western road before it went on to the Boston and Worcester road.

Q. 4. Were you inspecting and taking care of passenger-cars on the Boston and Worcester Railroad 15 years ago?

A. Yes, sir.

Q. 5. Among these cars were there the cars which formed the passenger express lines between New York and Boston?

A. Yes, sir. We had to inspect every car that went over the road. No car went over the Boston and Worcester road until it had been inspected.

Q. 6. How much of the time did you yourself attend to this inspection of the cars at the time referred to—about 15 years ago?

A. Every day and every other night, except once in a while when I was away, which was not often. In the whole time I have been on the road I have not been away a month.

Q. 7. Do you remember about 15 years ago that the cars of the express passenger lines between New York and Boston, running over the

Western and the Boston and Worcester roads, had on them a brake called the Springfield brake?

1275 A. I remember a brake by that name; what time it was put on I can't tell. I know the brake very well. The brake was on those express-cars.

Q. 8. Did you inspect those cars while they had this brake on them?

A. Yes, sir.

Q. 9. About how long did that Springfield brake continue in use on those cars?

A. I could not tell how long, but they were on quite a number of years. The time they were on was something I never took notice of.

Q. 10. Was it within the line of your regular duties as one of the inspectors of the cars running over the Boston and Worcester road at the time these Springfield brakes were on those express-cars, to know what was the opinion entertained about them by the persons employed on the trains on which they were used; and, if so, what was such opinion?

A. It was. The general opinion was that they were not good for anything; they were not a good brake. It was not as good as a single brake on one set of wheels; that is, on one truck; that was my opinion at the time. I have always thought so.

Cross-examined:

Cr.-q. 11. All the time you were inspector of cars, and while the Springfield brake was in use on the express-line, did you or not ever see any of the wheels slide under the brakes when the train came into the station?

A. I don't know as I ever did.

Cr.-q. 12. Did you ever see the wheels slide with the application of any brake when the train came into the station?

A. I don't think I ever did. I have no recollection of it.

Cr.-q. 13. Did the train frequently run by the station with the Springfield brake on?

1276 A. No, sir. It was seldom that any train ran by the station; they might have run by the length of the engine, or some distance. They generally stopped at one place, or came very near, but they might have run by.

Cr.-q. 14. Would the train be as likely to run by with any other brake as the Springfield brake?

A. I don't think it would make any difference what kind of a brake they had on. The engineer has the train under control when he comes in there, and can hold the train at any time at that place where I have been stationed. That is my judgment about it. The track would sometimes be slippery, and he might not be able to hold the train, but he was not under much headway when he came in there.

Cr.-q. 15. By what means would the engineer hold the train?

A. The engineer would reverse the engine if the train was going by.

Cr.-q. 16. Does the engineer reverse his engine at the present time, if the train is going by?

A. The engineer is not apt to reverse his engine unless he thinks it necessary.

Cr.-q. 17. After the Springfield brake was taken off and another brake put on, did the engineer reverse his engine when he was likely to run by the station while you were inspector?

A. Probably he would if he was going by. I have not been there to inspect cars for four or five years, and I don't know when the brake was taken off.

Cr.-q. 18. Was the brake on the express line cars some five or six years ago when you left inspecting cars at the Western railroad station?

A. That I couldn't tell you, whether it was on at that time or not.

Cr.-q. 19. You say you "know the Springfield brake very well." Will you please describe its construction?

1277 A. I am hardly able to do that. It is a complicated thing. I know the brake very well. I should know it if I should see it.

Cr.-q. 20. Supposing you should see a brake with four levers—one on each brake-bar—the levers being properly connected one with the other, and with the windlasses of the car—would you call such a brake a Springfield brake?

A. The Springfield brake had four levers, and so do other brakes. Every double brake has four levers that I have seen—except that there is a kind that has three levers, one of them under the centre of the car.

Cr.-q. 21. Did the Springfield brake have two equalizing levers under the body of the car?

A. I have already said that I can't tell the construction of the brake, but I should know it if I should see it.

Cr.-q. 22. Question repeated.

A. That is a thing that I can't tell you.

Cr.-q. 23. Did you ever apply the Springfield brake for the purpose of stopping the train?

A. No, sir; I had no occasion to do that.

Cr.-q. 24. What is the ground of your opinion for the statement that the Springfield brake was a poor brake?

A. The ground of my opinion is that it is complicated, that it had more length of chain than any brake should have, and that the brakemen couldn't work it as quick, and that they couldn't apply the power to it as quick, as to a single brake.

Cr.-q. 25. Did the Springfield brake have one or two chains attached to the windlass for operating the same?

A. It must have had two—one at each end of the car. It did have.

Cr.-q. 26. Did it have one or two chains attached to each brake-staff?

1278 A. That I couldn't tell you.

LORENZO HARDING.

Subscribed and sworn to this 17th day of September, A. D. 1872, before me.

WILLIAM B. HARDING,
Justice of the Peace.

HALFORD W. FENNER called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation.

A. Halford W. Fenner; am 47 years of age; reside in Worcester, Mass.; am an engineer at present; I run a locomotive engine.

Q. 2. On what railroad are you employed?

A. The Boston and Albany.

Q. 3. How long have you been employed on that road, including the time when it was called the Western road?

A. A little over 18 years.

Q. 4. What train are you running on that road at the present time?

A. The day express—between New York and Boston.

Q. 5. When you first went on to the Western road, what train did you run?

A. The Boston and New York night express.

Q. 6. For how long did you run the night express?

A. For about 11 and one-half years.

Q. 7. What year did that 11 and one-half years begin?

A. In 1854.

Q. 8. Between what points did you run the night express during this 11 and one-half years?

1279 A. Worcester and Springfield.

Q. 9. While you so ran this night express-train, do you remember a brake being used on it known as the Springfield brake?

A. I do.

Q. 10. About how long was the Springfield brake used on that train?

A. I should say somewhere in the neighborhood of a year; I can't swear as to the exact time.

Q. 11. What brake was used on that train just before the Springfield brake was put on it?

A. I think it was the Hodge brake.

Q. 12. While the Springfield brake was used on that train, how did it work?

A. The brake did not give good satisfaction; it worked poorly. We could not depend upon it always. We averaged a good deal poorer stops while the brake was in use than we did before or after it was used. I was afraid of the brake. In coming into stations I had to give the brakemen more lee way—shut off the steam further away from the station—and very often we would run by at that. A part of the time we had a Western Railroad car on the hind end of the train with a single acting brake; when that car was on, we could make better stops than we could without it, though it was one more car with the same number of brakemen—which was three and sometimes four, according to the number of cars.

Q. 13. After the Springfield brake was taken off of these night-express cars, what brake was put on in its place?

A. The Hodge brake.

Cross-examined:

Cr.-q. 14. Any more brakemen employed on this train when the Hodge brake was used?

A. No, sir.

Cr.-q. 15. Was there any less number?

1280 A. No, sir. The law compelled them to carry a brakeman for every two cars—for all trains running over 30 miles an hour.

Cr.-q. 16. What was the average speed of this express-line train when it had the Springfield brake on it?

A. I should call the average time at that time about 32 miles an hour. Some parts of the road—our road being a heavy graded road—we run at a speed of 50 miles an hour. Since and before the Springfield brake was used the average time has been faster and slower.

Redirect:

Q. 17. State whether while the Springfield brake was used on the night express-train, you frequently found fault with the brakemen for not holding the train well; and what, if anything, did they say the reason was they could not hold it?

A. My finding fault with the brakemen was of frequent occurrence.

They said the brakes were good for nothing, and could not hold the train, and that the brakes wouldn't brake twice alike.

Recross:

Cr.-q. 18. Did you ever complain to the brakemen because they didn't hold you with the Hodge brake?

A. I have, but not very often.

Cr.-q. 19. Is your not being held well always attributable to the brakes, and not to the men who operate them?

A. It is to both—both the brakes and the men.

Cr.-q. 20. If brakemen neglect their duty, will any brake, however good, hold you as you ought to be held?

1281 A. If brakemen neglect their duty and don't apply the brake, it is no brake, and one brake is as good as another.

Cr.-q. 21. May not the brakeman apply the brake and still in such a manner as not to effectually stop the train, however good the brake may be?

A. I should say not, if they applied the brake properly.

Cr.-q. 22. What would you call applying the brake properly?

A. A man putting his whole strength to the windlass and winding up the chain hard as he could without sliding the wheels.

Cr.-q. 23. Anything short of this, would it, in your judgment, be a neglect of duty?

A. In certain cases it would. There are cases, when coming into stations, where the forward brakeman don't brake as hard, and don't intend to, as the rear brakeman. The rear brakeman takes the slack of the train first; the forward brakeman then regulates the speed into the station. In that case the forward brakeman would not exert his whole power on the brake unless the train was likely to run by the station.

Redirect:

Q. 24. On the night express train, while the Springfield brake was used, did the same men act as brakemen before and after it was used as did so while it was used?

A. I could not state positively whether all the same men were on the train or not. Two of them were, both before and after, and while the Springfield brake was used.

Q. 25. Before and after the Springfield brake was used, did you, except rarely, have any trouble in being held by the brakes?

A. Very little.

Q. 26. As a general thing, how was it while the Springfield brake was used?

1282 A. The stops were poor, and we had considerable trouble, as I have said before.

Recross:

Cr.-q. 27. What do you call a poor stop?

A. If I am running at the rate of 40 miles an hour, and call for brakes, and the train runs a mile before stopping, I should call that a pretty poor stop—which is the stop I have made with the Springfield brake.

Cr.-q. 28. On what kind of a grade?

A. A descending grade, 50 feet to the mile.

Cr.-q. 29. Where located?

A. In the town of Charlton.

Cr.-q. 30. At any station; if so, at what station?

A. No; between stations.

Cr.-q. 31. Why did you call for brakes between stations?

A. Because of a disabled engine.

Cr.-q. 32. Do you know that the train ran a mile under the brakes?

A. I do.

Cr.-q. 33. How do you know it?

A. By the mile-posts on the road.

Cr.-q. 34. Do you know that each brakeman put on the brake the best they could from the time you called for brakes to the time the train stopped?

A. Personally I don't; all I know is what they said. They said they put the brakes on the best they could—the brakemen and the conductor too. They so reported to me.

Cr.-q. 35. Do you think the brake was in order at that time?

A. It was supposed to be when we left Springfield that night.

1283 Cr.-q. 36. How far do you think the train would have run had the single brake been on each car, and as effectually applied by the brakeman who ran on that train at the time?

A. The train ought to have been stopped in a good deal less distance than that. How quick the single brake would have stopped it I can't tell.

Cr.-q. 37. In how much less than a mile do you think the train ought to have been stopped with the single brake?

A. It ought to have been stopped in less than one-half of a mile.

Cr.-q. 38. What is the Springfield brake but a combination of two single brakes—or the brakes of both trucks—with each other and with the windlass of the car?

A. I don't see as there is much difference between the Springfield brake and the brake you describe.

Redirect:

Q. 39. Was this disabling of the engine you speak of in the daytime or night?

A. In the night.

Q. 40. When an engineer on an express train is running between stations at night, and calls for the brakes, is it or not expected on any railroad that the brakemen will do the best they can—not knowing what the trouble may be—to apply the brakes so as to stop the train in the shortest possible distance?

A. Yes; it is expected that they will do their duty first, and look out afterwards to see what the trouble is.

Recross:

Cr.-q. 41. Which do you think a brakeman at forty dollars a month would be likely to do first, in case of an emergency—to look out for himself and then apply the brakes, or apply the brakes and then look out for himself?

1284 A. At the rate of forty dollars a month, if he wanted to earn it afterwards, he would put the brakes on first, and then look out to see what the trouble was—for putting on the brakes would be his only salvation and that of the train. If he did not apply the brakes when he was called upon, but looked out first to see what the matter was and then applied the brakes, I should not consider him a fit man for a brakeman on any train whatever.

Cr.-q. 42. Do you think any brakeman who should look out before applying the brakes and see a collision ahead, that he would then apply the brakes and be crushed, or would he jump for dear life?

A. I think he would apply the brakes if he was a man—save his own life and the lives of the rest of the people in the train.

Cr.-q. 43. Do you know of any heroes among brakemen?

A. A good many.

H. W. FENNER.

Subscribed and sworn to this 17th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

SEPTEMBER 18TH, 1872.

JAMES P. PIERCE called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation.

A. James P. Pierce; am 63 years of age; reside in Worcester, Massachusetts; am a carpenter by trade.

1285 Q. 2. Were you ever in the employ of the Western Railroad Company—now Boston and Albany; and if so, about how long were you employed by them, and when did you leave their employ?

A. I was in their employ about 28 years. I left their employ three years ago last June.

Q. 3. While employed by them at what place were you employed, and what were your duties?

A. I was about three years at Springfield, and the rest of the time at Worcester. My duties were to repair and inspect the wood-work and general repairs of cars—temporary repairs.

Q. 4. Do you remember, while you were engaged in these duties at Worcester, that there was a brake called the Springfield brake used for a while on the cars of the express trains running between Boston and New York over the Western road?

A. I do remember.

Q. 5. Was it a part of your duty to inspect and look after the cars of those express trains during the time that said Springfield brake was on them?

A. Yes.

Q. 6. About how long, according to your recollection, was that brake used on said cars?

A. It was a short time. I couldn't state any definite time. It might have been a year—might have been two.

Q. 7. Was it in the line of your duty, as inspector and repairer of cars at the time this brake was used, to know what was the opinion about it held by the men on the Western railroad who ran on the train on which it was used; if so, what was their opinion of it?

A. Yes; they used to come to me about it. They complained about it that it was not good for anything—that it wouldn't hold. That was the general report about the brake—that it wasn't good—was a bad brake.

Q. 8. Was there any other man who helped you or worked with you in repairing or inspecting cars at this time; if so, who was it?

1286 A. M'r Boyden; but he was not always there, but he was at the shop.

Q. 9. About the time the Springfield brake was used on the express cars, do you know of orders being given by the officers of the Western railroad in reference to not using double-acting brakes on the cars running over that road; if so, what is your knowledge about it, and what were the orders?

A. Yes; I know of such orders. I know it from M'r Boyden and M'r H. P. Nichols. I think M'r Nichols gave me orders. He was general station agent at Worcester. The order was to unhitch the chains so that the double-brake couldn't be used. I mean the double-acting brakes.

Q. 10. State anything within your knowledge about what the men used to do to the double-acting brakes in carrying out those orders.

A. We used to unhitch the chains. We did it for a while, but I think not very long.

Q. 11. After the chains were unhitched, did the brakemen belonging to the train frequently do anything to them; if so, what?

A. The brakemen used to say that they hitched them up again, and I think I have seen them after they were hitched.

Cross-examined:

Cr.-q. 12. What kind of a brake was left on the car after the chain was unhitched?

A. None at all; that is, it couldn't be used while the chain was unhitched from the lever—to be more definite.

Cr.-q. 13. What was the name of the brake you had orders to unhitch the chain, and thus, as you say, entirely destroy the operation of the brake?

A. The Hodge brake.

Cr.-q. 14. Were the operatives of the train expected to run the same and stop it without brakes?

1287 A. That I don't know.

Cr.-q. 15. Did they run the trains in this manner?

A. They did; if they didn't rehitch the chains.

Cr.-q. 16. Did you understand that M'r Nichols, who gave the order, expected that the trains would be run with the brakes unhitched, as you have stated?

A. Yes, I think he did; he expected the order to be carried out if he gave it. I am not certain that he gave the order. I think either M'r Nichols or M'r Boyden gave the order, and I supposed the order came from headquarters.

(The supposition of the witness objected to by the counsel for the complainant.)

Cr.-q. 17. To what extent was the Springfield brake applied to the cars of the Boston and New York Express Line; that is to say, was it applied to a part of them or to all of the cars composing that line?

A. A part, I think.

Cr.-q. 18. What brake was on the remainder of the cars which did not have the Springfield brake on?

A. I think it was the single brake.

Cr.-q. 19. Are you quite sure that the single brake was used on any of the cars of that line while the Springfield brake was in use on the same train?

A. I am not sure about it.

Cr.-q. 20. Did not all the line cars have the Springfield brake applied to them at the time testified to by you?

A. I think not; I am not certain. I think only a part of them.

Cr.-q. 21. Did a part of them have the Hodge brake applied to them at the time the Springfield brake was in use on that line?

A. I am not certain about it. I rather think the Hodge brake was put on afterwards.

1288 Cr.-q. 22. Did you inspect the cars of this line every day, as a general rule, while the Springfield brake was in use on it?

A. As a general rule, I did. Some days I did not.

Cr.-q. 23. How many trains of this line running both ways, did you or M'r Boyden inspect in twenty-four hours?

A. Four trains, I think.

Cr.-q. 24. As a general thing, what number of cars composed each train?

A. I think about seven; might be eight, and sometimes more.

Cr.-q. 25. Of these seven or eight cars which composed each of the four trains, how many cars in each train do you think had the Springfield brake on?

A. I couldn't say.

Cr q. 26. How many according to your best recollection?

A. I couldn't make any statement about how many.

Cr.-q. 27. Do you think there was one car in each train that had the Springfield brake on it?

A. I couldn't state anything about that. Some days there might not have been any of those cars in those trains.

Cr.-q. 28. Can you remember that the Springfield brake was on any of the cars of the New York and Boston Express Line?

A. I think I do. I think it was on some of them.

Cr.-q. 29. How many of them?

A. That I don't know.

Cr.-q. 30. Was it on two cars?

A. I think it was.

Cr.-q. 31. Was it on three cars?

A. I couldn't say; it might have been on two or three or four. Don't know as I ever knew how many it was on.

1289 Cr.-q. 32. And yet you inspected those cars almost every day for a year, and yet don't know what brakes were on the cars; is that so?

A. I don't know now. I have forgotton.

J. B. PIERCE.

Subscribed and sworn to this 18th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

CHARLES G. PARKER called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation.

A. Charles G. Parker; am 49 years of age; reside in Worcester, Mass.; am a grocer.

Q. 2. How long have you been a grocer?

A. Ten years.

Q. 3. Were you ever in the employment of the Boston and Worcester Railroad Company? If so, in what capacity, and about when did you commence to be employed by them?

A. I was employed by the Boston and Worcester Railroad in the capacity of brakeman on a passenger train. I was two years on the first train in the morning, running from Worcester to Boston; then I went on the 9.45 train from Worcester to Boston—it connected with the first train that left Springfield over the Western road in the morning—these were the trains I ran on, except that occasionally I ran on the Albany express, so called, and on the New York express, which left Boston about 3 o'clock or 2½ o'clock in the afternoon. I first commenced to work on the road about March, 1854.

1290 Q. 4. In any of these trains upon which you so ran as brakeman, was there at any time a car from the Western Railroad which had on it a brake called the Springfield brake?

A. There was.

Q. 5. Which train did this car run in?

A. It ran in the train that I connected with at 9.45.

Q. 6. Between what places did you run on this train that had this car on it?

A. From Worcester to Boston, and return.

Q. 7. About how long was this car with this brake on it run?

A. I could not be positive, but it was not far from two years.

Q. 8. How many chains winding round the windlass staff at each end of the car did that brake have?

A. It had two.

Q. 9. For about how much of the time while that brake was used on that train did you run as brakeman on the train?

A. I ran as a brakeman on that train all the time that brake was used, except that occasionally I acted as baggage-master.

Q. 10. Did you as brakeman on that train have to apply that Springfield brake on that car?

A. I did.

Q. 11. How did that brake work?

A. It did not work well.

Q. 12. Will you please state what were the difficulties you had with it; what were the defects of it?

A. One great trouble with it was that the chains were very loose—there was two much slack; in winding up the brake the chains would overlap—consequently you lost your power of the brake. In winding the chains around the windlass, the windlass at that part became larger —in winding—by the several turns of the chain overlaying the first turn, consequently you lost your power. One other trouble was the
1291 chain being so slack it would drop under the step in which the lower end of the windlass-shaft was placed, and you couldn't apply the brake at all when the chain catched under there. I don't wish you to understand that it worked so all the time—that is, catched underneath—but it did occasionally. I repeatedly asked our car-inspector in Boston—I think it was Hutchins at that time—to take up the slack-chain, as I lost a great amount of time in turning the brake. He said that it couldn't be done and have the brake work well.

Q. 13. As a general thing, how did this Springfield brake work as to holding the car or train?

A. It did not work well. It did not hold the train—not so well as the old single brake.

Q. 14. Were there cars also run in that train coming from the Western road, which had on them the old single brake?

A. There were.

Q. 15. And could you hold the train better with those single brakes than you could with the Springfield brakes?

A. I could.

Q. 16. While you braked on that train, at what part of the train were you stationed?

A. One way over the road I was stationed between the Boston and Worcester Railroad cars and the Western—broke on both cars. It was

my duty to separate the cars as we came into Worcester—this was coming from Boston to Worcester—and in going from Worcester to Boston, perhaps half of the time I was stationed on one of the Western Railroad cars, and the other half of the time on the Boston and Worcester cars. I always preferred to brake on the Boston and Worcester cars because they had the Hodge brake. I could hold the the train better, and not run by the station so often as we did when I was braking on the Springfield brake. I considered the Springfield brake perfectly worthless. In case of an accident, I should not consider it safe at all. In coming out of Boston on that train we ran by stations one-half of the
1292 time, and had to back up again, until we got up to Framingham. They used to say to us that we didn't brake well; M'r Witherbee, the engineer, said so. I told him if he would give us the Hodge brake on all the cars, we could hold the train. He said he couldn't make his time over the road in shutting off steam so far from the stations, and he had to reverse his engine.

Q. 17. When this running by the stations occurred, what brakes were your trying to hold the train with?

A. I was using one Springfield brake and one Hodge brake.

Cross-examination:

Cr.-q. 18. How many cars composed this train?

A. We ran three passenger-cars and one baggage-car—Boston and Worcester cars—and two long passenger-cars, and one long baggage-car from the Western road; making seven cars in all. But many times we had on more than that, but this was the usual train.

Cr.-q. 19. How many brakeman were allowed to this train?

A. There were two brakeman to the Boston and Worcester cars, and one came down on the Western. We had two baggage-masters who broke their own cars; one on the Boston and Worcester part, and the other on the Western part of the train.

Cr.-q. 20. How many of the cars of this train had the Hodge brake applied to them?

A. The Boston and Worcester cars; three passenger and one baggage car.

Cr.-q. 21. What brakes were applied to the three cars that belonged to the Western road?

1293 A. One passenger-car had the Springfield brake; the other passenger-car and the baggage-car had the common single brake, so called.

Cr.-q. 22. Was this Springfield brake a double brake—that is to say, did it apply the power of the brakemen to both trucks of the car and from either end?

A. It was got up for that purpose. It was so called a double brake. Sometimes I thought it didn't act on either end. I think it was got up to evade the Hodge brake. I don't say it was—I merely supposed so.

C. G. PARKER.

Subscribed and sworn to this 18th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

JONATHAN G. WITHERBEE called and sworn.

Direct examination by M'r Cozzens:

Q. 1. State your name, age, residence, and occupation.

A. Jonathan G. Witherbee; am 62 years of age; reside in Worcester; am a keeper of a hotel.

Q. 2. Were you ever employed on the Boston and Worcester Railroad; if so, in what capacity?

A. I was employed on the Boston and Worcester road 19 years—the last 17 of them as a locomotive engineer.

Q. 3. Do you remember what year you went on to the road and what year you left?

A. I left the road 13 years ago last August. It was 19 years before that, that I went on to the road.

1294 Q. 4. While you were locomotive engineer there, what trains did you run on?

A. I run on most all the trains; the last seven years I run on the accommodation train between Worcester and Boston. The first two years the train left Worcester at 7 o'clock a. m. The last five years it left at 9.30 a. m.

Q. 5. Did the train last spoken of connect with a train coming from Springfield over the Western road?

A. Yes, sir.

Q. 6. Do you know M'r Charles G. Parker; and if so, state whether he used to run on this train last spoken of as brakeman?

A. I do know him; he did run on this train as brakeman.

Q. 7. Do you recollect of there being in that train one car which came from the Western Railroad and which had on it a brake called the Springfield brake?

A. Yes, sir.

Q. 8. About how long was that Springfield brake used on that car?

A. I should think about a year, or a little more.

Q. 9. How much of the time while that car with that brake was in that train did you run the train?

A. Most of the time.

Q. 10. Do you remember how many chains winding round the windlass staff at each end of the car that brake had; if so, how many?

A. It had two.

Q. 11. How did that brake work as to holding the car or train when it was applied?

A. It worked bad; there was not much dependence to be put upon it.

Q. 12. What kind of brakes were there on the other cars in that train, during the time this Springfield brake car was run in the train?

A. There were single brakes.

1295 Q. 13. From what road did these cars with the single brake on them come?

A. From the Western road—as it was called then.

Q. 14. Which brake held the car best—the Springfield brake or the single brake?

A. The single brake, I think, was the most reliable.

Q. 15. Please state whether, during the time that this Springfield brake was used on this train, you 'ver complained to the brakemen, and, among others, to M'r Parker above named, about the train not being stopped properly by the brakes?

A. I did complain a great deal about it, and they would say they were not to blame. I did complain to M'r Parker.

Q. 16. State whether or not this train, which had this Springfield brake on it, when it was attempted to be stopped at stations, would frequently run by the stations before stopping?

A. It would.

Q. 17. What, if anything, did you do as engineer to aid in stopping said train at stations?

A. I reversed my engine and backed up to the station.

Q. 18. State whether you used to reverse your engine, under headway, to aid in stopping this train at stations?

A. I used to, frequently.

Q. 19. About how many cars, on the average, were run in this train from Worcester to Boston and return—including the cars which came from the Western road?

A. There were, on an average, 9 cars in this train to Boston—sometimes ten.

Q. 20. Please state about how many of these cars, on an average, came from the Western road, and how many from the Boston and Worcester road?

1296 A. Five from the Boston and Worcester road, and four from the Western—that was the regular train. The cars from the Western road were longer than the Boston and Worcester cars.

Q. 21. What kind of brakes were on these cars from the Western road, except the car that had the Springfield brake on it?

A. They had on single brakes.

Q. 22. And what kind of brakes on the cars that belonged to the Boston and Worcester road?

A. They were the Hodge brake.

Q. 23. How many brakemen were employed on this train?

A. There were three on the Boston and Worcester cars and three on the Western cars—making in all six—including the baggagemen of the two trains—which were made into one train at Worcester—there were two baggagemen on this train, and they sometimes braked.

Q. 24. Did you at any time run as engineer over the Boston and Worcester road on either of the express passenger trains between New York and Boston?

A. I did often—frequently exchanged with other engineers.

Q. 25. Did you use to run those express trains at the time when they had the Springfield brake on them?

A. I did.

Q. 26. How did the Springfield brake work on those express cars as to holding the trains?

A. They did not hold good; it would take more than as much again time to stop the trains at stations, as with the other brakes.

Q. 27. While running those express trains with the Springfield brake on them—did you frequently have to reverse your engine under headway to aid in stopping the trains at stations?

A. I did—oftentimes.

1297 Q. 28. You have said that it would take more than as much again time to stop those express trains at stations as with the other brakes; what other brakes do you refer to?

A. I refer to the Hodge brake.

Q. 29. Did you run on those express trains before the Springfield brake was put on them—and also after it was taken off of them?

A. I did.

Q. 30. At those times—before and after the Springfield brake was used on them, what kind of brake was on the cars when you ran them?

A. The Hodge brake.

Q. 31. State whether when the Hodge brake was used on them, you had any difficulty in stopping at stations?

A. None, unless the rails were bad, snow or ice on them, or something of that kind.

Cross-examination:

Cr. q. 32. When the Springfield brake was in use on those express line cars, was it applied to all the cars composing that line?

A. I should think not. It is my impression that there was one car in each train that had the Hodge brake on. I should say so, but am not positive.

Cr.-q. 33. Was this car with the Hodge brake on from the Boston and Worcester road, from the Western road, or was it an express line car?

A. I think it was a Boston and Worcester car.

Cr.-q. 34. With the exception of this one car with the Hodge brake on, did the other cars of the train have the Springfield brake?

A. I think they did.

Cr.-q. 35. Why was the car with the Hodge brake on attached to the train at Boston, and run through to Worcester and back, if it was so attached and run?

A. I don't know as I can give any reason. It was often run so.

1298 Cr.-q. 36. Was it for the reason that an increased number of passengers took the train at Boston for Worcester, and at Worcester for Boston?

A. There was a car run in that way for that purpose. There was a car run through to Springfield on those trains. I don't know the reasons why they run it. Sometimes they had passengers to fill it, and sometimes they did not. I mean the car run in the express train over the Boston and Worcester road.

JONATHAN G. WITHERBEE.

Subscribed and sworn to this 18th day of September, A. D. 1872, before me.

W'M B. HARDING.
Justice of the Peace.

Royal Boyden called and sworn.

Q. 1. State your name, age, residence, and occupation?

A. Royal Boyden; am 47 years of age; reside in Worcester, Mass.; am the master mechanic for the Boston and Albany road, formerly the Western road, at Worcester.

Q. 2. How long have you been employed on that road?

A. Have been on the road 17 years steady work. Have been master mechanic about 11 years in all; the first 10 years of this time commenced about 15 years ago, and then, after I had been master mechanic about 10 years, the company sent another man here, and he was master mechanic for about 4 years, during which time I was his assistant; he left last January, and since that I have been master mechanic again.

Q. 3. Do you remember about 15 years ago knowing of a litigation between M'r Hodge, the patentee of the Hodge car brake, and the 1299 Western Railroad Company; and do you know of orders being given at that time in reference to unhitching Hodge brakes when they came to the Western road; and if so, please state what those orders were?

A. I heard about a trouble between Hodge and the Western road in a roundabout way; did not have it directly from the officers. I knew there was some trouble about the brake business. I do know of orders being given about unhitching the Hodge brakes. I had orders to unhitch the brake-chains from the Hodge brake, and we did unhitch them.

Q. 4. Was this unhitching continued for a while and then given up ?

A. Yes.

Q. 5. During the time that the unhitching was continued, do you know whether brakes were ever hitched up again by the brakemen before the trains went out from Worcester over the Western road ?

A. I know of one instance.

Cross-examined:

Cr.-q. 6. To what company did the cars belong, the brakes of which orders were given to unhitch, and to what place were said cars destined after the unhitching had taken place ?

A. I don't remember to what company the cars belonged, and I can't say to what place the cars were destined.

Cr.-q. 7. What cars, at the time the orders were given, had the Hodge brake on them; were they Western cars, or Boston and Worcester cars ?

A. That I couldn't say. I know they were foreign cars—we called all cars outside of the Western road foreign cars—and when they came there we unhitched them.

Cr.-q. 8. Were the cars which made up the New York and Boston express line known to you as foreign cars ?

1300 A. We called them line cars.

Cr.-q. 9. Did you understand the order to apply to these line cars ?

A. I can't say as to that. I know we did not unhitch the brakes of those cars.

Cr.-q. 10. If a car belonging to the Boston and Worcester Railroad Company chanced to be in a train with a Hodge brake on it, and liable to be run over the Western road, did you disable said brake by unhooking its connections ?

A. I don't recollect of ever doing it to a Boston and Worcester car.

Cr.-q. 11. Counting out the cars of the Boston and New York express line, and those belonging to the Boston and Worcester Company, what other cars with the Hodge brake on would be likely to run over the Western road ?

A. I couldn't tell as to that.

Cr.-q. 12. Were there passenger-cars with the Hodge brake on belonging to any other line or company than those above named, which came to Worcester in any train on its way over the Western road ? If so, name the company or companies to which said cars belonged.

A. I couldn't tell now to what road they belonged to.

Cr.-q. 13. Were the cars on which you detached the brakes sent on their way without any brakes on which the brakemen could rely in stopping trains in case of an emergency ?

A. That I don't know. After I unhitched them, it was the extent of my duty.

C.-q. 14. After the brakes were unhitched were they by this act incapacitated for stopping the car in case of a necessity to do so ?

A. I can't answer that.

Cr.-q. 15. In unhitching the Hodge brake on foreign cars, what
1301 did you do in order to fulfill the order which you say you received
from the officers of the Western road ?

A. I just barely unhitched the hook from the brake-lever.

Cr.-q. 16. From the brake-levers of each truck ?

A. Yes.

Cr.-q. 17. Will you now please state, as master-mechanic, whether the Hodge brake, unhooked as you have stated, would be of any service whatever in stopping the car in case of an emergency?

A. It would not after it was unhooked.

Redirect:

Q. 18. Have you a distinct remembrance of unhitching the Hodge brakes from foreign cars which came to Worcester bound over the Western road, although you can't now recollect the names of the companies to which such cars belonged?

A. I have unhitched the chains, but I can't tell to what road the cars belonged. I have a distinct remembrance of doing that.

Recross:

Cr.-q. 19. Did you yourself unhitch the chains of more than one car?

A. Yes.

Cr.-q. 20. How many more?

A. I could not tell how many more; quite a number of them.

Cr.-q. 21. How long did you continue this unhooking?

A. It was a month certain that we unhitched the chains.

Cr.-q. 22. At what time was the order countermanded?

A. I don't remember of having any order in regard to that.

1302 Cr.-q. 23. Did you presume to violate the order by ceasing to unhitch the Hodge brake on foreign cars?

A. I have nothing to say.

Redirect:

Q. 24. You say you don't remember any order countermanding, but you have said that after a while the unhitching was discontinued; what led you to discontinue it?

A. I can't answer that.

Q. 25. Do you remember, at any time after receiving the order to unhitch, hearing that the Western Railroad Company had obtained the right to use the Hodge brake?

A. I don't recollect; I have nothing to say about that.

ROYAL BOYDEN.

Subscribed and sworn to this 18th day of September, A. D. 1872, before me.

W'M B. HARDING,
Justice of the Peace.

Deposition of George H. Gardner, taken at Boston, Sept. 21, 1872.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. Geo. H. Gardner; age, 29; residence at present at Charlestown, Mass.; occupation, brakeman on the Boston and Maine Railroad.

Int. 2. How long have you been brakeman on the Boston and Maine Railroad?

A. Since the 2d day of August, 1872.

1303 Int. 3. How many years in all have you been brakeman on different railroads?

A. Since sometime in June, 1866; I can't state the date—about the middle of June, 1866.

Int. 4. During this period, what kind of trains have you broke upon?

A. I have, I think, broke upon almost all kinds of trains, except gravel-trains, that have been run—freight, passenger, accommodation, and express.

Int. 5. Where were you braking before, or shortly before, you went on to the Boston and Maine Railroad?

A. On the Boston and Albany, sir.

Int. 6. About how long a time did you brake on the Boston and Albany Railroad?

A. The last time that I was there—I have been on the road three different times; I have been away on vacations at times—I commenced April 19, 1872, and remained until the 30th day of June, 1872.

Int. 7. During this time did you brake on a train known as Conductor Jennings' train?

A. Yes, sir.

Int. 8. Did that train have in it cars with brakes on them known as the Springfield brake?

A. Yes, sir.

Int. 9. Between what points did you run as brakeman on that train?

A. Between Boston and Springfield, and return.

Int. 10. Going out of Boston, how many cars were run on that train?

A. Five, as the general number.

Int. 11. Returning from Springfield to Boston, how many cars were run in that train?

A. Six; sometimes seven; and as many as eight or nine at different times.

Int. 12. Do you recollect how many cars there were run in that train which had these Springfield brakes on them?

1304 A. Baggage-car, mail-car, smoking-car, and two first-class passenger-cars—five cars in all, I think.

Int. 13. When the train had in it six or more cars—when it was returning from Springfield to Boston—what kind of brakes were on these other cars, not the Springfield-brake cars?

A. What they called the Hodge brake, I think.

Int. 14. The sixth car generally came behind, and took the slack of the train?

A. Yes, sir. My station was on the rear car always.

Int. 15. About how much of the time, when that train was returning from Springfield to Boston, would it average six cars?

A. During the week of the Jubilee we had various numbers, but as a general thing there were six cars.

Int. 16. And this sixth car, you say, had the Hodge brake on it?

A. Yes, sir.

Int. 17. While on that train, did you yourself brake on any of these Springfield-brake cars?

A. Yes, sir.

Int. 18. When you broke on any of said Springfield-brake cars, at what part of the train were you stationed?

A. At the rear of the train.

Int. 19. When you broke on said Springfield-brake cars, how did said brakes work?

A. Well, sir, they worked very poorly.

Int. 20. What difficulties did you find with them in holding the train?

A. Well, they couldn't hold the slack of the train. Going from Boston to Springfield, we had five cars, and generally I had to put one brake to use myself—going to Springfield. I had but one to use to take the slack of the train. I had the Springfield brake every other day.

Int. 21. And how do you say that this Springfield-brake car would take the slack of the train?

1305 A. Not very well. I often told the brakemen on the forward end of the train not to touch the brakes until I took the slack of the train, and then brake up as quick as they could, so as to run up to the station and make a quick stop. I found that wouldn't work, because I would set my brake as hard as I could, and they would wait for me to take the slack of the train, and we would very often run by. I would ask them why they didn't brake, and they would say they were waiting for me to take the slack.

Int. 22. Why did you request them to wait until you had taken the slack of the train, and then brake quick?

A. I always made that a rule, while braking on the rear of all trains.

Int. 23. When braking on this rear car with the Springfield brake on it, were you or not able, when the brake was applied, to keep the car from running upon the car next ahead of it?

A. No, sir; they often ran together. I spoke to the conductor a number of times about it—that they must have the brake fixed, and they said they would. I told them that I would like to have them shifted out, and have a car put behind that I could take the slack with.

Int. 24. Was it ever, while you were on the train, fixed so that this difficulty was obviated?

A. It was reported a number of times, and they said they had fixed it; but I failed to discover any improvement in it.

Int. 25. Did you notice how these Springfield brakes, when they were applied, worked when the car passed from a straight track to a curve, or on to a reverse curve? And, if so, state how they worked.

A. I think it worked rather poorly on a curve; not so well as on a straight line. I noticed a number of times, when I set the brake on a straight line, and run on to a curve, I would find, after setting it
1306 as hard as I could on a straight line, on running round on a reverse
curve, that I could set it a little more then; it would slacken it; and going on a curve the other way—reverse curve—I would find I had done all I could; I couldn't set it any harder.

Int. 26. Did you complain to the proper persons connected with the railroad about the operation of these Springfield brakes?

A. Yes, sir.

Int. 27. Did you do so more than once?

Ans. I think I had run on the train about three days when I reported them the first time.

Int. 28. What did you say about them when you so reported them the first time?

A. I reported at Springfield, to the man who looks the trains over there, and told him they would have to take the connections up or put some new shoes on; that I couldn't hold the train or the car. He told me that it could not be done there; that it would have to be done in Boston.

Int. 29. Was it finally done in Boston?

A. The next trip the car came back to Boston. I reported it in Boston, and told them they must put some new shoes on.

Int. 30. Were new shoes put on at this time, or soon after?

A. They were put on car 123 the same night. They refused to do it at first, but I told them I was told in Springfield to have it done in Boston, and they went to work and put them on to car 123, and it was so late that they said they couldn't put them on 124—so they sent the train off. But when they came back the next round trip, they were put on car 124.

Int. 31. State whether this putting on new shoes improved the working of the brake any.

A. I think it held a little better. I thought, by the way it worked, the connections had not been let out. They had been taken up some with the old shoes on.

1307 Int. 32. You say it worked a little better. State whether it worked well enough to enable you to take the slack of the train.

A. I would set the brake, and I would hold my car back—take the slack of my car; I would set the brake as hard as I could set it, and when the brakeman ahead would apply the rest of the brakes (they had two apiece and I only had one), then I couldn't keep my car from them. I mentioned it to the conductor, I think, once or twice; told him I would like to have a different car behind, or a different brake; because if the train should break apart I should be sure to run into them.

Int. 33. Did you at any other times complain of the manner in which the brake worked?

A. Yes, sir.

Int. 34. State whether, at any time after any of these complaints, it was fixed so as to remedy these defects.

A. I saw no great improvement in it after reporting it. I reported it to the man who does the switching. I asked him if he wouldn't shift 123 out, and let me have 124 behind, and see if that would do any better; but he didn't do it.

Int. 35. State whether, while you broke with these Springfield brakes, the train would ever run by the stations.

A. Yes, sir; very often.

Int. 36. Did they run the Hodge brakes in this train every other day?

A. Yes, sir.

Int. 37. When the train had all Hodge brakes on it, was there any difficulty in stopping at stations?

A. No, sir; I found that it required a good deal of judgment on that train. I never was on a train where it required so much judgment as it did on that train; there was so much difference between the Springfield brake and the Hodge brake. When we had the Springfield brakes on I worked very hard, and we very often ran by. I would go to Springfield and would have the train back with the Hodge brakes on, and very often I took hold of the Hodge brakes the same as I had been working on the other train; I would brake up quick and very hard, and very often I would stop short of the station. 1308

Int. 38. With which brakes, the Springfield or the Hodge brakes, did you commence to brake the farthest back when approaching stations?

A. The Springfield brake. I generally took the slack of the train the length of the train sooner with that than with the Hodge.

Cross-examination by M'r Whipple:

Cr. 1. Was the Springfield brake ever in working order while you operated it?

A. I never considered that it was, properly.

Cr. 2. What trouble did you find in operating the brake, as applied to car 123?

A. When I first reported it, I found that the shoes were all worn off.

I would set the brake up—wind it clean up to the rod, or near it, so that I couldn't do any more.

Cr. 3. That is to say, you had no control over the wheels—the chain was so short?

A. I thought that was the trouble with it.

Cr. 4. Did you find the same difficulty with No. 124—the shortness of the chain?

A. The chain was longer on 124, but I didn't have any occasion to use that much.

Cr. 5. Could you, at any time, hold or take the slack of the train with car 124, with the Springfield brake?

A. I never had that car behind to take the slack of the train with, to my knowledge.

Cr. 6. You always had No. 123 with your train?

A. When we didn't have the other cars, I had that—one way.

1309 Cr. 7. This short chain would come up solid against the hook of the brake-shaft on which the chain winds?

A. It would fetch up under the platform solid, so that I couldn't do any more. It would come to a bearing underneath.

Cr. 8. Which do you mean, the brake or the hook, came up solid against the shaft?

A. The hook, under different circumstances. Setting the brake is different. There is as much difference in setting it as the different positions you would get a car in.

Cr. 9. Had the connections been taken up or made longer, and new shoes put on, would the Springfield brake have worked well, in your judgment?

A. I think it would have worked quite well on a straight line, but on a curve I think it would not work well.

Cr. 10. What curves are there on the Boston and Albany Railroad, and where are they located, on which you observed a difference in holding, whether on a straight track or a curve?

A. Backing the train from the house here in Boston, in this passenger station.

Cr. 11. How sharp was that curve on which you made this observation?

A. Well, sir, there was considerable of a curve there. We backed out on something like an S; not so very much of a curve—something of the shape of an S, and run out on to a reverse curve. In backing out from the station, passengers would run across the street ahead of me, and I would set my brake and hold a bit, just to keep the cars steady, as they would throw them out, and when I would come around that curve they would almost stop. I would throw off my brake, and I would find it was set very hard. When I would come around the other
way, on the other curve, the brake would be set a little, and
1310 and I would find it all slack and not holding any, and then I
would have to set it up considerable.

Cr. 12. In your judgment, would the operation of the brake be affected on any curve that is in the main track out of the city of Boston, and between it and the city of Springfield?

A. I think, sir, if the curve in Boston here would affect the brake a great deal, it must be affected to some extent on any curve, in any situation.

Cr. 13. Do you think the operation of the brake would be sensibly affected on the curves as they appear ordinarily on that road?

A. I do, sir.

Cr. 14. To what extent do you think the operation of the brake would be affected on a curve of 800 feet radius.

A. I think to apply the brake on a straight line—going from here to Springfield on a straight line—and turn round to the right on a curve, it would slacken.

Cr. 15. On such a curve as the question names? and I name the sharpest curve in the main line of that road.

A. Yes, sir.

Cr. 16. If you could be relieved as brakeman for a while from the Boston and Maine Railroad, would you go on the Boston and Albany Railroad and operate the brakes on cars 123 and 124, and state with what result?

A. Yes, sir.

Redirect by M'r Cozzens:

Int. 39. You have said that under some circumstances the hook of the connecting rod would be drawn clear up against the windlass shaft. Did this take place when you were applying the brake on straight lines, or when you were applying it on curves?

A. On curves.

1311 Int. 40. With which brakes, the Hodge or the Springfield, did you have to work the hardest?

A. With the Springfield brake.

Int. 41. Are you a strong, powerful man?

A. I consider myself so.

Int. 42. What effect did this working harder produce on your hands?

A. Well, I had some of the sorest hands I ever had in my life, and my hands didn't look quite so bad as the rest of the brakemen's on the train.

Int. 43. In this respect how does the Hodge brake affect your hands when you use that in your ordinary business of braking?

A. They are an easier working brake. I think they are generally cast iron, and very smooth—painted, I should judge. With the Hodge brakes you can set them up very hard, and still you can swing on them and gain a few inches more. With the Springfield brake I would set that up hard and it would seem to come to a standstill; I would brace myself back and swing on it very hard, and I found I couldn't gain anything. It would give me a considerable racking.

Int. 44. As you ordinarily use the Hodge brake in your experience as brakeman, do you find that it callouses your hands much of any?

A. Not very bad. In my six years' railroad experience I was never on a train that I worked so hard on as I did on that Springfield-brake train.

Int. 45. In how much less distance, if any less, could you stop a train with the Hodge brake than you could with the Springfield brake?

A. I think I could stop a great deal quicker and with more ease; I never have tried to see. [I have always noticed that the men on the train would very often tell me that they had a pretty easy run of it; they would say that when we got in, and I would ask them if they didn't have to brake just as hard as they ever did, and they would
1312 say, no, they didn't hardly touch the brakes.] We very often took on car 67, I think at Worcester, that had the Hodge brake on it, which is as good a brake, I think, as I ever got hold of, although it is an old car; I could almost hold the train alone with it, and very often I had to let it off to let the train up to a station; and then I would ask the men what they broke so hard for—why they didn't let the train

run up before they stopped it; and they said they were not braking; and I came to the conclusion then I was holding the train alone.

Int. 46. Could you judge in about what relative time you could stop a train with the Hodge brakes as compared with the Springfield brakes; whether twice as quick, three times as quick, or as the case may be?

A. I think I can stop a train the length of it quicker with the Hodge brake than with the Springfield.

Recross by M'r Whipple:

Cr. 17. Is the wheel of the Springfield brake on car 123 painted?

A. I think not. It is made of rough casting. I once reported that to M'r Ray, and asked him if he wouldn't take that old brake-head off and put another one on; it tore my hands so, it was so rough; but he didn't do it. I think the other brakemen on the train reported it when they had it.

Cr. 18. Did you ever have occasion to complain that the Hodge brake did not work well?

A. Not very often, sir. Once, I think, I broke the brake-chain on one of them; reported it, and it was fixed.

Cr. 19. Are all brakes liable to get out of order?

A. Yes, sir.

Cr. 20. When out of order can you depend upon them to hold a train?

1313 A. When a brake is out of order I always make it a rule to report it and have it fixed as soon as possible, or set the car off.

Cr. 21. On what train are you now acting as brakeman, on the Boston and Maine Railroad?

A. I have no regular train, sir; I am freight-shifter in the yard, and doing out-of-town work.

Cr. 22. Are you usually at the depot of the Boston and Maine Railroad in this city?

A. I am at the freight depot in the morning.

GEORGE H. GARDNER.

Deposition of Robert W. Bibber, taken at Boston, Sept. 21, 1872.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. Robert W. Bibber; age, 45; residence, South Boston; occupation at present, sailing-master of a yacht.

Int. 2. Were you ever employed as locomotive engineer on the Boston and Worcester Railroad?

A. I was.

Int. 3. About how many years did you run on that road as locomotive engineer?

A. Twenty years, sir.

Int. 4. About how many years of this time, if any, did you run as locomotive engineer on the New York and Boston express lines over that road?

A. About 17 years.

Int. 5. Part of this time did you run on the day portion of those lines and part of the time on the night portion?

A. For four years I run the day line.

Int. 6. The rest of the 17 years the night line.

A. Yes, sir.

1314 Int. 7. Do you remember that, a number of years ago, there was a brake called the Springfield brake put upon the cars of those express lines?

A. Yes, sir; on what we termed the through cars, running from Boston to New York.

Int. 8. Did you run the trains during this time that these Springfield brakes were on them?

A. I did, sir.

Int. 9. Please state as to how these Springfield brakes worked as to holding the trains.

A. Well, sir, I did not consider them reliable at all times.

Int. 10. During the time that these Springfield brakes were on these trains who was the brakeman or baggage-master on whom you chiefly relied on the train which you ran?

A. Well, the baggage-master or brakeman was baggage-master up and brakeman down. He was local baggage-master to Worcester and rear brakeman from Worcester to Boston—the man that I relied upon coming to Boston.

Int. 11. And what was his name?

A. John Moran.

Int. 12. At any time while these Springfield brakes were used on that train do you recollect any circumstance connected with the repair of a bridge at Grafton in reference to how those brakes would hold a train? If so, please state it.

A. I do, well. The abutments of the bridge at the foot of Millbury hill, near Grafton, within three-quarters of a mile of the depot, were rebuilt, and during the rebuilding the tracks were thrown together. We had to reduce the the speed to about three miles an hour over that portion, and I have often noticed there were times that he would hold me at that, and at others he said he couldn't.

Int. 13. This was while the Springfield brakes were used, was it?

A. Yes, sir.

1315 Int. 14. You say "he." Whom do you mean?

A. Moran—as he was the man that I relied upon.

Int. 15. While this Springfield brake was used, would or not the trains frequently run by the stations?

A. There were times, sir, that they would be stopped short, but more times run by.

Int. 16. Did you or not, while these Springfield brakes were used, have to reverse your engine to aid in stopping the trains?

A. Yes, sir; quite often. In coming over this portion of the road where they were rebuilding this bridge, I often had to come over it with the engine reversed.

Int. 17. What was the name of the brake that was used on those cars before and also after these Springfield brakes had been used?

A. Really, I can't tell you.

Int. 18. Was it the Hodge brake?

A. I think it was, sir, but I won't be positive. But we used to term it "the double brake."

Int. 19. Did you, while the Springfield brake was used on these cars, observe whether the brakemen had to apply the brakes at an earlier point when approaching stations than they did when the Hodge brake was used?

A. I did, sir.

Int. 20. When you were using the Hodge brake on those trains, did you have to reverse your engine to aid in stopping the trains?

A. No, sir.

Cross-examination by M'r Whipple:

Cr. 1. What year was it that the Springfield brake was used on the New York and Boston express line?

A. I think it was in the spring of 1857. It has been some few years since I left the road, sir, and it has somewhat slipped my memory.

1316 Cr. 2. How long were the Springfield brakes in use on the New York and Boston express line cars?

A. I can't tell you how long, but I should judge about a year.

Cr. 3. Were they applied to all the cars on that line?

A. I think they were, sir; I won't be sure.

Cr. 4. You say that the Hodge is what you called "the double brake"?

A. It used to be a term we used, sir.

Cr. 5. Was the Springfield brake termed a double brake, also?

A. I think not, sir.

Cr. 6. What was it called?

A. I never heard it called anything but the Springfield brake, sir.

Cr. 7. Did it operate on both trucks at the same time?

A. I believe, sir, that both trucks were connected with the same windlass shaft.

Cr. 8. In that case they would operate on both trucks, would they not?

A. To a certain extent, sir.

Cr. 9. Is any brake anything more than connecting the two trucks with each other, and operating them from one windlass shaft?

A. I think they are, sir.

Cr. 10. Wherein do they differ?

A. I think the difference is with the double lever, sir.

Cr. 11. How many levers are there in the Hodge brake, and how many in the Springfield brake?

A. I think there are two in the Springfield.

Cr. 12. And how many in the Hodge?

A. I think there are three, if I am not mistaken. It has been some time since I looked these matters over.

1317 Cr. 13. Then you would not call a brake that connected both trucks with the windlass, and operated them at the same time, a double brake?

A. Not in the manner that the Springfield brake did, sir.

Cr. 14. What was the average speed that you were required to run the New York express train at that time?

A. It was 32 miles per hour.

Cr. 15. How many stops were you required to make between Worcester and Boston, with the Springfield brake?

A. Well, at different times we had first to stop for this bridge, then at Westboro', Framingham, and Newton Corner; at other times we only had to stop at Framingham.

Cr 16. Going either way?

A. Either way, sir.

Cr. 17. If I understand you, you run this train of express cars only from Worcester to Boston and return?

A. That is all.

Cr. 18. And made, ordinarily, one stop—that is, at South Framingham?

A. Yes, sir.

Cr. 19. Was it a frequent occurrence with you to run by the station at South Framingham?

A. While we used the Springfield brake, sir.

Cr. 20. Did you ever run by there with the Hodge brake?

A. We might at times when the track was slippery—wet; but with a good rail, not.

Redirect by Mr. Cozzens:

Int. 21. Was it a frequent occurrence with the Hodge brake?

A. No, sir; it was not.

Recross by M'r Whipple:

1318 Cr. 21. Might it not have been a frequent occurrence, had the rail been wet, slippery, or frosty?

A. It might have been, yes, sir; with a frosty rail.

Redirect by M'r Cozzens:

Int. 22. When the rail was good, was it or not a frequent occurrence with the Springfield brake?

A. Yes, sir. It was often stopped short, also, with the Springfield brake.

Int. 23. Do you know why it was that they often stopped short with the Springfield brake?

A. Yes, sir.

Int. 24. Please state why.

A. They couldn't govern the brake; that is, they would put it on a mile back, at times, to be sure.

Recross by M'r Whipple:

Cr. 22. Was it, as a general rule, applied a mile from the station?

A. It was not, sir. The rule was the brakeman's judgment.

ROBERT W. BIBBER.

Deposition of William O'Brien, taken at Boston, September 23, 1872.

Direct examination by M'r Sayles, in person:

Int. 1. What is your name, age, residence, and occupation?

A. William O'Brien; age, 24; residence, Boston; occupation, brakeman on the Boston and Albany Railroad.

Int. 2. How long have you been brakeman on the Boston and Albany Railroad?

A. About four years, sir.

1319 Int. 3. On what trains?

A. Passenger trains. My first work on a train was on the owl train—out from Boston at half-past eight. I ran on that train about six months; then I was spare brakeman for a few weeks; then I ran on what we call the 9.45 train—going out from here in the morning, rode up to Worcester dead-head, and broke coming back, getting here at quarter before 12; then I went out on the train that left here at 7 o'clock in the morning and got back at quarter-past six.

Int. 4. What trains have you been braking on during the last six months?

A. Jennings' train was the first train I went on when I came back on the road. It left here at 5 o'clock in the morning, and got back at half past 3.

Int. 5. What kind of brakes were used on the cars of Jennings' train when you were braking there?

A. We had two kinds; one day we had the Springfield brake out of Boston, and the next day we had the Hodge. We would have the Springfield brake up from here in the morning, and the Hodge brake down in the afternoon. The next day we would have the Hodge brake out from here in the morning, and the Springfied brake back in the afternoon.

Int. 6. Between what places did you run?

A. Between Boston and Springfield.

Int. 7. Who was rear brakeman on Jennings' train when you were running on it?

A. When I first went on there was a fellow by the name of Braman—a stout fellow. He broke on the train with me perhaps a week after I went there, and then there was a man came on by the name of Gardner. He was an old brakeman, but he had been off, the same as I had, but came back again, and went on this train.

Int. 8. How did the Springfield brakes work in stopping the trains at stations?

A. Well, we would go out from here in the morning with the
1320 Springfield brakes on; we would come to the Providence crossing; that don't amount to much of a stop any way; and on that train he used to whistle for brakes at stations, and we would run up close; I have had him call for brakes at stations, and we would go away by on him. The way of it was, they used to find fault with the parties; one would find fault with the other, say he didn't brake; Gardner would say I didn't brake, and I would say he didn't brake, because he never took the slack of the train in going round curves, or anything like that, with that brake; for instance, if there was a station where there was a curve just before getting to it, nine times out of ten we would go by the station; we supposed we had the brakes set, but when we came to find out they wouldn't be set; there would always be a catch in them somewhere; in one instance—at Brimfield, a flag station on the Western Railroad about twenty miles from Springfield or a little more—where we were due to meet the train that leaves Springfield at quarter-past seven (we left at five), as we were going in there one morning—we were running slowly; the engine was shut off; she wasn't working any steam—this Springfield train had got in there and was just stopping. Of course, we had to stop, because it was against the rules to allow two accommodation trains to come into a station at the same time, and be called for brakes. I set my hind brake as hard as I could and stepped over and set my forward brake as hard as I could; used all my strength, and was leaning over to look out, and it seemed as if I could feel the brake was not set, and I swung round and set it at least a dozen notches, if not more. That scared me, because when they whistle for brakes every man is supposed to set his brakes as hard as he can, and finding they were not set, when I supposed they were set hard, I was scared; I thought the conductor would report me for not doing my duty, and for not setting the brakes hard, but he didn't—
1321 as he generally does when they whistle for brakes—come out
and set the brake. Then another day—coming down with that brake (I mention these things about it)— we were coming into Riverside and he whistled for brakes again, and as I set the brake I felt a sharp yank, and the brake-wheel went right away from me and threw me against the railing, and I wasn't quick enough to get my wrist from the brake-wheel, and the skin was torn off the whole side of my hand, and I couldn't hardly use it for a week. I used to use it some, because it didn't take the strength out of it, but it was sore whenever I touched anything. And quite frequently I used to feel that yank, and I would feel kind of sore after I had been there a week, and I couldn't think what it was that made me sore. The brake would give a sort of yank, and the wheel would pull right away from me, in spite of all my power.

Int. 9. At what time was this pulling of the brake away from you?

A. It used to be when we came to those stops at Cordaville and Riverside and Brimfield. I don't know as I used to notice it so much at Brimfield, but at Cordaville and Riverside it threw me very hard against the railing, and not being quick enough to get my hand off the wheel, it gave me a sharp yank.

Int. 10. Was this on going round from a straight track on to a curve?

A. Yes, sir; it was just as we came on to the curve at Riverside; and Cordaville is on a curve, too, and Brimfield is on a curve.

Int. 11. If I understand you, while you were applying the brake in going from a straight track on to a curve, when it struck a curve it would jerk the brake-wheel out of your hands?

A. Yes, sir; I used to feel it at Spencer, too. It is down grade there, and the train goes very rapidly, because it is upon a hill—down 1322 a sharp grade—what we call the Spencer grade—and going in there in the morning before now the train would run by. The brake would give that yank, and of course it would jerk the wheel out of my hands, and I would have to brake up again. We would be going in there at what seemed a dead stop, and all at once there would seem to be a sort of rattle, or something, and that would make the train slide right by on a jump. I used to speak to Ned Jennings, the car-inspector at Springfield, and tell him to take up the chain. The lower chain would go down underneath and catch in the nut, and it would bother me, because there would be no chance to get a purchase on the other chain to amount to anything.

Int. 12. Did you have any difficulty in stopping trains at stations when you had the Hodge brake on the train?

A. Oh, no; Lord bless you, no. We never had any trouble with that. We could always make good stops with the Hodge brake. Coming down here, we run together, and George Gardner used to say we would make good stops coming down. Says he, "We have got a good brake to day, and I have got the hind end of the train, and you wait until I take the slack." I says, "I will." We have actually gone by Indian Orchard and there would be no remark made. Luke Hodgkins would be the engineer, and be late, and we would go by Indian Orchard twice the length of the train.

Int. 13. How long were you on Jennings' train?

A. I was on there a month; I knew that by drawing pay. I should say I was there five weeks, if not more. I went on two or three days before the month came in, and stayed there until after pay-day. The fourth working day we got pay.

Int. 14. How many cars were run on this Jennings' train in coming from Springfield to Boston?

A. We generally used to have six down.

1323 Int. 15. How many cars had the Springfield brake on?

A. I believe five.

Int. 16. What brake did the sixth car have on it?

A. The Hodge, I think.

Int. 17. How many cars did you have in the train going to Springfield?

A. Five out of Boston.

Int. 18. Did all five of these cars have the Springfield brake?

A. Yes, sir; one morning up.

Int. 19. How did the Springfield brake work on a straight track?

A. Sometimes it would hold very well on a straight track; and then again, going into Brookfield—there is a curve going into there, just before you get to the station, and then it is a straight track—I have seen it work first rate, hold the train, and I have seen us go by there with it. But generally we were running very slow there. There wasn't much braking there at all.

Int. 20. You say sometimes it would work very well on a straight track?

A. Yes, sir.

Int. 21. I should judge, then, your idea was that it would work better sometimes than it would at other times on a straight track?

A. Yes, sir.

Cross-examination by M'r Whipple:

Cr. 1. Are you still employed as brakeman on the Boston and Albany Railroad?

A. Yes, sir.

Cr. 2. On what train are you running now?

A. I leave here at 11 o'clock in the forenoon and get back at half-past 6. The "Worcester accommodation," they call it. It is a new train put on the 10th of June.

(The deposition was read to the witness.)

1324 Cr. 3. Have you heard your testimony all read over to you since you gave it?

A. Yes, sir.

Redirect by M'r Sayles:

Int. 22. You spoke of its making you sore. Where did it make you sore?

A. Right across my chest; in the cords, right here.

Int. 23. What made that?

A. All the way I could account for it was the yank I used to get from the Springfield brake, because I didn't feel it until I went on that train, and when I got off of it for three or four days I was quite sore, but afterwards I got over it. I haven't felt it since.

Recross by M'r Whipple:

Cr. 4. Do you authorize the commissioner to sign your name to this?

A. Yes, sir.

W'M O'BRIEN.

Deposition of Hervey Waters, taken at Boston, Sept. 23, 24, and 25, 1872.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and profession?

A. Hervey Waters. Age, 68. Residence, Boston. Machinist.

Int. 2. Please state what have been your opportunities for acquiring a knowledge of mechanics and machinery?

1325 A. I am a machinist by trade and have been employed in machinery since I was 16 years old, and for something more than 20 years of my life last past I have been accustomed to the examination of patents and the drawings connected therewith, and to giving evidence thereupon in the [illegible] tes courts.

Int. 3. Were you engaged as expert in the litigation between Ross Winans and the railroad companies several years ago, in reference to the eight-wheel railroad-car; if so, for about how long a time were you engaged in that litigation?

A. I was engaged in that controversy on several occasions, on the part of the railroads, running through some 15 years or more, I believe.

Int. 4. Will you state what opportunities you have had of acquiring a knowledge of railroad-car brakes and of their operation, and state whether you have ever been called upon to testify as an expert in any suit upon letters patent for improvements in car brakes?

A. My attention was first called to the operation of car-brakes and to patents for improvements thereon, some 18 years ago, I believe, in the trial of a case at Albany against the Erie Railroad for infringing the patent of Batchelder and Thompson assigned to Tanner. Since that I believe I have, on one occasion, helped try a case at Canandaigua against the Central Railroad, on the part of Hodge, the plaintiff; and since that a case at Windsor, on the part of the railroads in a suit brought upon the Turner patent against the railroads.

Int. 5. Will you state whether you are familiar with the construction and operation of the car brakes known as the old single brake and the Springfield brake?

A. I am. I have had occasion to look into their mode of operation considerably.

1326 Int. 6. Was there testimony given by you or by anybody else in your hearing, respecting said single brake and Springfield brake, in the suit mentioned by you as having been tried at Albany on the Tanner brake patent?

A. I do not now remember as to any testimony at Albany upon the old brake, but I do remember that the Springfield brake was pretty fully discussed there, and that evidence was introduced upon it there on the part of the railroads. I heard the car described there by a gentleman from Springfield, whose name I do not now remember. I recollect the description of the car pretty well.

Int. 7. Have you examined a certified copy of the letters patent of the United States issued July 6th, 1852, to Henry Tanner, as the assignee of Batchelder and Thompson, for an improvement in car brakes; and, if so, do you understand the construction and operation of the mechanism therein described?

A. I have, and I understand the contrivance therein described.

Int. 8. Are you familiar with the construction and operation of the two forms of double-acting car-brake known respectively as the Hodge brake and the Stevens brake?

A. I am.

Int. 9. Will you please state any conditions which occur to you as being involved in the problem of successful braking of the class of cars known as eight-wheel cars—as they are now run and during the time you have been familiar with car-brakes, have been run—upon railroads in the United States? Please answer fully.

A. The method of bringing up a train of cars upon a railroad when they are running thereupon, requires the employment of the same means that are employed for getting that train in motion; and by "the same means" I refer to the bite of the wheels upon the rails. In getting the train in motion, it is accomplished by means of the driving wheels of the locomotive biting upon the rails of the road. 1327

In bringing up the train when the locomotive is not reversed, the train is brought up by the bite of the other wheels of the train upon the rails; and as this is the only available force which can be used, a proper braking involves the use of all the other wheels except the wheels of the locomotive. It is not desirable to use the driving-wheels of the locomotive to bring up the train, because this cannot be done

without reversing the motion of the engine which is objectionable. Now, it is important that this bite of the wheels upon the rails should be used as nearly to its fullest extent as possible, and therefore the brake should be applied as nearly to the point of friction which will overcome the bite upon the rails as possible and what will bring up the train in the least possible time. If this is exceeded and the wheels are made to slide upon the road by applying the brakes too tightly; the train will not be brought up as soon as it will if the wheels do not have the brakes applied quite so tightly. Now, this last proposition is not always accepted as true by parties who think they understand this problem, but it is true, nevertheless; and any person who has ever observed the working of a locomotive in its attempts to start a heavy train of cars, will have observed that sometimes the wheels of the locomotive are made to slide upon the rails before the train is in motion. Now, whenever this takes place it is necessary to reduce the pressure of the steam upon the pistons of the locomotive, so that the wheels may come to a stand-still upon the rails before the train can be put in motion. The bringing up of a train of cars by means of the brakes is the converse of this. If the brakes are applied so tightly as to cause the wheels to slide upon the rails they will have to be loosened until the wheels bite upon the rails before the full braking effect of the brakes upon that train can be utilized. So that, in consequence of this fact it
1328 becomes necessary that the windlasses of a car should be so proportioned that the brakeman must use nearly his whole available strength in order to brake up the train, or else he will be in danger of putting his brakes on too tight and thereby to a large extent defeat the very purpose which he has in view in applying the brakes.

Another proposition is that in order to brake up a train of cars effectually, all the brakes should be applied as nearly simultaneously as possible, producing thereby the least jar upon the train, and bringing the same up within a shorter distance than can be accomplished in any other way. Now, the railroads of this country are generally considerably crooked—more so than they are in other countries, where the lines of road are not so long as they are here, and where more money per mile is put into them; and for that reason it has been necessary to use the eight-wheel cars—and by that I mean, not simply cars with eight wheels, but eight wheels in two trucks, four wheels in each truck—because it has been desirable to have the cars of considerable length, and in order to run the long cars upon crooked roads it has become necessary to introduce these trucks. Now, the trucks themselves are what the old cars were—they have two axles and four wheels, the same as the old car had, and these two axles are considerably near together in the truck—usually about as near together as the rails are in the track; and by the use of these trucks it has become practicable to have the car bodies very long and still run curves without any difficulty. But the very fact of the introduction of these trucks to the cars has produced a difficulty in the application of the brakes. It will be easily understood that if the brake was applied upon the truck itself—the same as it was upon the old car—the state of things would be very different from what it is when used upon the long car, where the windlass is of necessity upon the
1329 body of the car, but the levers and the brakes are upon the trucks of the car so that there has to be a connection between the body of the car and the trucks of the car, for the purpose of working the brakes upon the trucks of the windlass upon the body of the car.

There is also another condition which comes in here, in consequence of the use of these long cars, and the way they are used in this country.

The passage-way between the seats is fore and aft of the car, and not only fore and aft of the car, but fore and aft of the train, so that an alley-way is left from one end of the train to the other; and therefore the windlass, which is for the purpose of bringing up the brakes, must be placed upon one side of this alley-way, and outside of the central line of the cars. Now, this fact of placing the windlass in this position makes it necessary to have a peculiar manner of connection between the windlass and the truck levers. That connection must be such, in order that the brakes should work well, as to enable the trucks to turn upon their king-bolts so as to accommodate themselves to curves without varying essentially the tension of the parts which act to bring up the brakes from the windlass upon the body of the car. This matter of the two trucks under the long body of a car was the subject-matter of the Winans patent, which was in controversy some twenty years in the courts of this country; but those trucks have gone into general use, and the use of them has always involved this difficulty, to which I have referred, of connecting the windlass with the trucks. It was involved in the old cars before the double brakes were attempted, when the brakes were single, because the windlass being upon one side of the line of the king-bolts, and it being necessary to make an attachment from the windlass so as to act longitudinally with the car, it was necessary to make the connections to the trucks upon one side of the king-
1330 bolts; and, therefore, whenever those trucks ran from a straight line onto a curve, or from a curve onto a straight line, there was always difficulty with the old brakes. Now, the Springfield brake was so constructed that a connection was made, not only from the windlass to the truck-levers of one truck, but also to the truck-levers of the other truck; but this difficulty of the connection was involved in both of them—considerably worse in the truck nearest to the windlass than it was in the truck farthest from the windlass. But the Springfield car had also a second windlass, at the opposite end from the windlass which I have referred to, and which, just like that, was connected to the two trucks. But it never got over this difficulty which existed, of producing a variation in the tension of the brakes by the swivelling of the trucks; that remained in it just as much as it did in the old car. And it had another difficulty, which the old brake did not have. The old brakes, being only connected to one truck by one windlass, and to the other truck by another windlass, were each independent of the other, so that no correct adjustment was necessary. But in this Springfield brake, where the two connections were made from the windlass, one to one truck, and one to the other truck, another difficulty arose which was worse than the old brake. It not only rendered it very difficult to adjust these two connections so as to work equally upon a straight line, but when they were so adjusted as to work equally upon a straight line, they could not work equally upon a curved line, and vice versa. That trouble did not exist in the old brake.

I have said that in the braking up of a train of cars it was desirable to apply all the brakes simultaneously, as nearly as might be, and from this it follows that the less number of men that are necessary to brake up a train the better, everything else being equal. And in making this statement, I do not mean to include the expense of the men. It
1331 is better, if the expense is the same, because it is easier to get two men to work in concert than it is to get four men to work in concert, and therefore the Springfield brake was better than the old brake, from the fact that a single individual could apply the brake to the two trucks, where it took two individuals to do the same thing be-

fore; and if this had been accomplished so as to work equally, the Springfield brake would have been a great improvement; but, being coupled with the difficulty which I have mentioned, I do not consider that it was an improvement at all, and I believe that experience has so proved it. And, in fact, for safety, leaving out the expense, I think the old brake is better than the Springfield brake, for the reason that the Springfield brake, although it saves half the men, brings with it other difficulties which are worse than the employment of twice as many men, especially to the passengers that ride upon the road. It is more liable to accidents, and a train cannot be brought up with it, under all circumstances, so quick as it could with the old brake, using twice the number of men.

At the present day the most popular and the most efficient brake is the Westinghouse. The only peculiarities of this brake are, first, that it is operated by a single mind, or at the call of a single mind, without being obliged to signal to others; and, second, that it can be operated uniformly upon all the brakes of the train. The brakes are just the same as they were before; there is nothing new in them; the novelty is in the more ready application of the brakes, and application with greater uniformity. It is more expensive than the old brake, for two reasons: in the first place, it is very costly; in the next place, it is difficult to keep in order, and the brakemen are not dispensed with, because if a train is broken apart, then the Westinghouse brake is entirely useless, as I understand it, and the brakemen have to go to the brake-
1332 windlasses as they did before, and therefore, I believe, they are always taken along on the train, as far as I know; at any rate, they always should be. But it is a great security, because, in case of an emergency, the brakes can be applied at once by the engineer, who is more likely to see the emergency than anybody else; and they can be applied with such uniformity as to make every wheel in the train tell to its utmost; so that a train may be brought up, perhaps, in about half the time, or half the distance, that it could be brought up by the old contrivance; because, although the brakes are the same, they cannot be got on soon enough to prevent the accident. Suppose that by bringing up the train in 300 feet, the accident was avoided, when, if it run 600 feet, it would be fatal. This I understand to be the great benefit of the Westinghouse contrivance; not that the brakes are any different—they are just as they were before—but they are more efficiently worked; more efficiently worked, because they are worked quicker and more uniformly. The Batchelder and Thompson patent describes a swivelling car with eight wheels in two trucks, and a double-acting brake acting upon those trucks; and this is the first contrivance, as far as I know, which avoided, almost, if not altogether, the difficulties incident to the trucks in a car, as they are used in this country, and is the first, as far as I know, to which the Westinghouse improvement has ever been applied. Subsequently to this, there was a modification of this contrivance of Batchelder and Thompson, by Nehemiah Hodge, for which he took letters patent. That modification is susceptible of being used with the Westinghouse contrivance, and is so used. One Stevens also made a modification of this Batchelder and Thompson brake, for which he took letters patent, and this is susceptible of use by the Westinghouse improvement, I believe. But I have never known of this improvement being applied to the Springfield contrivance, and I take it it
1333 would not make a good practical car-brake in any way—in connection with the contrivance or without it. At least, I know of no way by which the Westinghouse improvement might be applied to

it so as to make it a good brake; so that this contrivance of Batchelder and Thompson seems to have been the first which avoided the difficulties incident to the running of cars as they are usually constructed and run in this country, and upon which the Westinghouse improvement could be used. Batchelder and Thompson, by their contrivance as it stands, and as it is described in the patent, being of such a character that good braking could be done by one-half of the men which it was necessary to use in using the old brake, so far as the concentration in a single mind goes, went the first half of the way—they got rid of one-half of the men; and Westinghouse has reduced the other half to a single individual.

Int. 10. You have said, in the answer just finished, that when the old cars with the single brakes passed from a straight track on to a curved track, and vice versa, there was always a difficulty. Will you please state more fully than you have yet done what that difficulty was?

A. By "the old cars" there, I do not mean any other than the eight-wheel cars—because that difficulty did not exist when there were no trucks upon the cars. Now, the windlass being necessarily placed upon one side of the central line of the cars, longitudinally, and it being necessary to make the connection from the windlass to the levers in the truck in a line parallel to the length of the car, or nearly so, in order that the truck levers may act properly, it will be readily understood that any swivelling of that truck round the king-bolt would change the relation of the top of the truck lever—which is attached to the truck—to the windlass which is attached to the body of the car; so that if the car took a curve in one direction, the connection would
1334 be tightened, and if it took a curve in the opposite direction, the connection would be loosened; and therefore it was impossible, so far as I know, to so proportion the parts in any way, when that was the arrangement, as to avoid this difficulty.

Int. 11. You have also stated that the Springfield brake had this same difficulty, together with another difficulty which the old single brake had not. Will you please state how it is that the Springfield brake comes to have this same difficulty, and also please to state what the result in the practical use of the Springfield brake is, in consequence of its having the other difficulty from which the single brake is free?

A. The connection of the windlass to the truck nearest to the windlass was substantially the same in the Springfield brake that it was in the old brake which preceded it; but there was also upon the same windlass the connection to the other brake of the car. Now, it will be seen that without the connection to the other brake of the car, the same difficulty existed in it that existed before in the old brake; and the connection to the second brake mentioned had the same difficulty, though not to so great an extent. And, besides this, there was a further difficulty in the necessity of such an adjustment of these two connections that they might work equally even upon a straight track. Now, if this adjustment was so made as to produce an equal pressure of the brakes upon the wheels when on a straight track, then, when running on to a curve in one direction, the brakes on one truck would be tightened, and on the other would be loosened, because, when one truck turns one way the other truck turns the other way. But suppose the car took a curve in the opposite direction—then the connection which was tightened in the former instance would be loosened in this instance, and the one which was loosened before would be tightened.

1335 Int. 12. Have you a diagram present with which you can illustrate the effect upon the Springfield brake of the passage of the car from a straight track, with the brakes applied, on to a curved track; and, if yea, will you please state the scale of length of car body upon which such diagram is made, and will you state the different radii of curves to which the diagram is applied?

A. I have such a diagram. It is drawn to a scale of half an inch to a foot. The extreme length of the car-body represented in this diagram is 45 feet. The different radii represented are 500 feet, 400 feet, 300 feet, 200 feet, and 100 feet; and one of the drawings represents a car upon a straight track.

Int. 13. Will you, by means of this diagram, illustrate fully what would be the effect in the use of the Springfield brake of the application of the brakes to a car with trucks, when running upon a straight track and then passing from such straight track on to tracks of the different respective radii represented in the diagram?

A. According to this diagram, a car, in passing from a straight track on to a curve of 500 feet radius, varies the relation of the end of the truck lever to the windlass at one end of the car about an inch and a half, so that, by such change, the brake would be drawn tighter upon the wheels of the truck to the extent of what would be due to a turn round the windlass far enough to draw the lever an inch and a half, which would amount to several notches upon the ratchet-wheel as it is usually used upon the brake. The truck at the other end of the car would not be affected quite so much, and whatever it was affected would be by shortening instead of lengthening. This effect I cannot measure quite so accurately as I could the other, because my instruments will not span over the space; but as nearly as I can measure with the scale,
it would be shortened very nearly an inch and a quarter, so that
1336 the variation of both together—one in one direction and the other
in the other direction—amounts to two inches and three-quarters, very nearly. The other curves make the differences more. The extreme one—which I understand to be an extreme representation—where the radius is 100 feet, makes the variation very much larger. It is, in that case, at one end of the car about seven inches and a half that the space is increased between the windlass and the truck lever, and the connection to the other truck is shortened five inches. With the radius of 200 feet, the corresponding measurements are 3½ and 2½ inches, respectively, very nearly. With the 300 feet radius, the corresponding variations are two inches and an inch and a half, very nearly. With the radius of 400 feet, the corresponding variations are an inch and a half—large—or about an inch and five-eighths, and an inch and three-eighths, as nearly as I can make it out.

Int. 14. Will you please state what the various lines and circles upon the diagram are designed to represent, and will you please mark the various parts with letters?

A. If I mark one of these diagrams, it will be sufficient for the whole of them, so far as I have referred to them heretofore, and I will place the marks upon that diagram which represents the straight track. A A represent the lines of the track or rails in the railroad; B represents the body of the car; C C represent the trucks; D D the windlass wheels; *a a* the windlasses upon the shafts, with the windlass wheels; *b b* the king bolts upon which the trucks swivel; *c c* the axles of the trucks upon which the wheels are made fast; *d d d d* the ends of the truck levers to which the connecting rods of the truck are pivoted; *e e e e* the connecting rods.

Int. 15. Upon the scale upon which the figures of this diagram

1337 are made, what is the diameter of the windlass wheels as represented in the various figures?

A. The circular lines which represent the windlasses are 14 inches in diameter.

Int. 16. And what is the diameter of the windlass shafts in the figures?

A. These drawings represent them as about two inches, where the chains wind on them.

Int. 17. I notice that in the figure of the diagram which represents the Springfield brake car as stand on the straight track, the tops of the truck-levers which are denoted in the figure by the letters *d d* are just about over the railroad rails. Please state whether this is the proper position for the tops of said levers when the car is on the straight track?

A. It is about the proper position. The windlass is placed where it is upon the body of the car as represented in this diagram. That position of the windlass was taken from the cars which are running on the Boston and Providence Road, which have upon them the new Springfield brake as recently applied upon that road. These windlasses are placed in about the same position upon the body of the car that they are placed upon those cars.

Int. 18. Please state whether you have yourself seen the Springfield brakes on those Boston and Providence cars, and have measured the distance of the windlass shafts on those cars from the central longitudinal line of the car?

A. Of course I have, or else I couldn't swear that these are like them. And I will also say, in addition to what I have said, that the distance between the rails as represented by this diagram is about four feet, eight inches, or eight and a half, which I understand to be the distance between the rails on the Boston and Providence road, or very nearly that.

Int. 19. How material in the practical use of the Springfield brake would be these variations to which you have testified as exhibited by this diagram?

1338 A. I consider it a grievous fault in that contrivance, and such as to render it valueless for all practical purposes when compared with the brakes of the present day. What I mean by this is, that no road, in my judgment, could afford to use it so long as they could obtain the other brakes for any reasonable compensation.

Int. 20. Will you now, as you have testified to the diagram, bring together in a single answer what you have thus far stated to be in your opinion the comparative advantages, on the whole, of the single brake, in contrast with the Springfield brake on the whole?

A. The comparisons between the old brake and the Springfield brake amount to about this, in my judgment. It is likely that in using the Springfield brake upon a train of cars, the immediate expense to the road would be somewhat less than in using the old brake, because one-half the number of men could do the work, as far as they could do it, upon the Springfield brake. But as an offset to this, I bear in mind the difficulties of adjustment on the Springfield brake. They are very great, from the fact of these extraordinary strains which will at times come upon it, as I have stated, and also from the fact that at the best, when the two brakes are made to act together upon a straight track, the adjustment of the connecting rods must be very accurate. Now, this adjustment will require to be done quite often, and at considerable expense, because men of considerable skill are required to do it, and

this will be so much out of the gain which will be made by using the Springfield brake with half the men. But as a matter of safety, it is likely that so far as the Springfield brake acts correctly upon a straight track, there will be greater safety in using it than in using the other, because there is only half the number of men to do the work,
and can be made to act more nearly simultaneously than
1339 double the number of men. With these differences, I still
should prefer, as a matter of safety, to have the old brake, although the expense might be greater when the old brake is used. In the old brake this necessity of comparative adjustment is done away with, because the two windlasses do not act in common upon the two brakes, and with double the number of men the brakes can be more equally applied, under all circumstances, with the old brake, than they can with half the number of men with the Springfield brake; and I would sooner take the additional expense of the single brake for its greater safety, than take the less expense of [the Springfield brake with less safety.

Int. 21. Have you recently seen any tests made with the Springfield brake which tend to illustrate the conclusions about it above stated by you? If so, where did you see such tests; how was the brake constructed for the tests, and what was the result of the tests? Please answer fully.

A. I have seen such experiments at Providence, on the rails of the Providence and Worcester Railroad, and I believe, also, the rails which are used by the Boston and Providence Railroad, in the yard there. I saw there an old freight car upon which there had been placed recently brakes to represent the Springfield brakes, and I saw that when those brakes were set tight on a straight track, and run from that track on to a curve, the wheels of one truck would take to sliding, and when it passed from that curve to a reverse curve, the wheels of the other truck took to sliding; and, in both instances, the wheels of the truck which did not take to sliding were quite loose under the action of the brakes. I do not mean that they were absolutely free, but I mean that they were so loose that the brakes upon them did little or no good. Those curves were extreme curves, not such as are used in the line of the
road, as I understand it, but they proved what the tendency of
1340 that brake is. I afterwards saw the same car tried upon curves
of larger radius. Both pairs of wheels of one truck did not take to sliding, but one pair of wheels did. This is because, in the truck levers, as usually applied, one pair of wheels is held tighter by the lever than the other pair is in the same truck in all the cars that I know of, except where the Stevens brake is used, and when one pair of wheels in one truck took to sliding, the wheels of the other truck were considerably looser than they should be.

Int. 22. Did you pay particular attention to the mode of application of the brakes to the car in this test, and to the circumstances of the test; and if you did, state whether or not the test was in all respects a fair one?

A. I did; and the test was in all respects a fair one, so far as I know, with the exception that on this old car the windlasses were placed considerably nearer the central line of the car than they are usually placed on the passenger-cars, as I have observed them, and I think some eight or ten inches nearer, as well as I remember, the central line than what the windlasses are upon the Boston and Providence cars, where the Springfield brake is now, I think; and that is not quite a fair representation of the Springfield brake, because, in order to have a convenient car, it would be necessary to place the windlasses farther out, and that would aggravate the difficulties which I have mentioned.

Int. 23. It has been testified in this case, with reference to this test, by M'r Olney L. Smith, the car-master on the Providence and Worcester Railroad, who was present at said test, that the length of the car-body of this car was about thirty feet, over all. Please state how this length of car compares with the average length of passenger-cars in the United States, and whether or not the difference would favor the operation of the Springfield brake?

1341 A. I cannot speak officially as to the length of the passenger cars. My impression is that they are considerably longer than this car which I saw there, and the longer a car is between the king-bolts of the car, the worse the Springfield brake will act upon it.

Int. 24. Is there or not, in the Tanner brake, as represented in the Tanner patent, any provision for avoiding this bad result which you have shown to exist in the old single brake and in the Springfield brake —that is, the effect upon the brakes of the passage of the car, with the brakes applied, from a straight track to a curved track, and vice versa? If there is, please state what it is.

A. There is. The combination and arrangement of the Batchelder and Thompson brake, as applied to a car, and as described in the letters patent, is such that the passage of a car from a straight track to a curve of 100 feet radius will produce very little variation in the relative distances which are occupied by the connecting rods—so that that car can run from a straight track to a curve of 100 feet radius without producing any considerable variation of the tightness of the brakes upon the wheels, and if it can do that, it certainly can do anything that is required of it on common railroads, because, as I understand it, it is not often that there is a curve on the regular track of a railroad so small as a radius of 100 feet—or even so small as a radius of 500 feet, and the greater the radius, the less the variation will be in the requirements of the brake. This is accomplished in the Batchelder and Thompson contrivance by the use of a central lever attached to the body of the car, which is connected at each of its ends with each of the windlasses upon the body of the car. Now, inasmuch as this lever is pivoted to the body of the car, it is obvious that the going from a straight line on to a curve—which only affects the truck—will in no way affect this lever with the windlasses and its connections—which is altogether upon the body of the car. But there is a connection between the central 1342 lever and the truck levers. This connection, however, is made in such a manner that a straight line drawn from the point of connection upon this central lever—which is attached to the body of the car—to the lever which is upon the truck, will pass nearly through the king-bolt upon which the truck swivels; so that when, by means of the swivelling of the truck, the end of the truck lever to which the pivoted connection is made swings, it does not swing lengthwise of the car, but swings crosswise of the car, taking the connecting-rod something out of a straight line in the direction of the king-bolt, first one way and then the other, so as to produce a slight angle in the connections, but not so as to make any considerable variation of the distance from the end of the truck lever to the point upon the centre lever attached to the body of the car to which the connection is made.

Int. 25. So long, then, as the various levers are arranged as they are seen to be in the Batchelder and Thompson patent—so that the line of draft from the centre-lever to the tops of the truck levers is nearly in a line with the king-bolt of the swivelling truck, can there be any variation in the effect of the brakes, when the truck swivels, which will be at all material under any ordinary circumstances?

A. There cannot.

Int. 26. Does this combination and arrangement of the various parts prevent the alternate lengthening and shortening of the connections which you have stated produces so bad an effect in the old single brake and in the Springfield brake?

A. As a mathematical fact it does not, but as a practical fact it does.

Int. 27. Is there any difficulty in the practical construction and application of brakes to eight-wheel cars having trucks, in so combining and arranging the parts of the Tanner brake as to secure these advantages?

1343 A. There is not. The Tanner brake requires that the two connections to the central lever should be so adjusted as that they shall baer equally upon the wheels of both trucks of the car whether they are on a straight line or whether they are on a curved line; and the passage of the car, when so adjusted, from a straight line to a curved line will not make any material change in the relation of those parts, nor will it make any material change in the tightness of the brakes when they are once properly applied.

Int. 28. Can you illustrate this provision of the Tanner brake, and the effect of it, by means of the diagram to which you have already referred? If you can, please do so.

A. The drawing in the patent illustrates that, and this diagram is similar to it. One of the figures on this sheet of diagrams represents the Batchelder and Thompson contrivance upon a straight track, with the brakes applied. The other represents it with the brakes applied upon a track of 100 feet radius, and upon inspection it will be observed that in the position upon the track of 100 feet radius the ends of the brake levers upon the trucks to which the connecting-rods are pivoted is the same distance from the point upon the centre lever to which they are connected as is represented when the contrivance is on a straight track. This will be seen on reference to the points represented at *b b* on figure X, and *a a* on figure Y. There should be, mathematically, a difference here, but the difference is so small it would be difficult to detect it upon a drawing of this size. There is a little error in the drawing, I perceive, so that one of the connecting-rods—say at *b b* in X—is a little longer than at *a a* in X; but it will be obvious that this difference is very small, because it can never vary more, under the circumstances here represented, than what is produced by the change in length from a straight line between the points *a* and *c* in figure Y, to the length of line produced by the angle *a a c* in figure Y.

1344 Int. 29. In the Tanner brake, are the truck levers spoken of attached to the brake bars of the trucks in such a manner that they can vibrate more or less in a direction crosswise of the car when the brake is applied?

A. They are.

Int. 30. What effect, if any, does this have in reference to the equality of the application of the brakes when the car passes from a straight track on to a curve?

A. The effect is to allow the connecting-rod to pull more in a direct line toward the centre of the king-bolt than it would if the lever was rigidly guided in its action upon the truck; so that the swivelling of the truck will actually produce less *less* change in the connecting-rod than what is represented by the diagram.

Int. 31. Referring now to the Hodge brake, please state what, if any provision, that contains for securing a substantial equality of application of the brakes when the car passes from a straight track on to a curve?

A. The Hodge brake can be so constructed as to secure uniformity of tension, or nearly so—uniform for all practical purposes—in the action of the brake-rods when the car passes from a straight line on to a curve. And this is accomplished in a similar manner in the Hodge brake to what it is in the Tanner brake. It is by using levers in the combination that a uniformity may be maintained which could not be maintained without the levers; and it is partly from this, and partly from the fact that the two windlasses—being upon the right-hand side of the passage-way of the car—are so situated that there is a compensation between the two trucks by means of the use of those levers. When one swivels towards its adjacent windlass, the other swivels away from its adjacent windlass.

1345 Int. 32. How nearly, then, may the tops of the truck-levers of the Hodge brake draw in line with the king-bolt of the swivelling truck, when the brake is applied and the car passes from a straight track on to a curved track, and vice versa?

A. The Hodge brake may be so constructed as that the draft will be nearly in a line with the king-bolts; how nearly I am unable to say.

Int. 33. Can the Springfield brake cause the draft of the truck levers to be thus nearly in line with the king-bolt when the car passes from a straight-track on to a curve?

A. No—so long as the windlass wheel is outside of the passage-way from car to car.

Int. 34. Can the Stevens brake be so constructed that the levers in the trucks, or either of them, will draw nearly in a line with the king-bolt of the swivelling truck when the car with the brakes applied passes from a straight track on to a curve?

A. Not so well as the Hodge brake can; but something of it can be and is accomplished as the Stevens brake is usually constructed, where the windlasses are one upon one side and the other upon the other side of the passage-way between the cars.

Int. 35. Which of the levers in the respective trucks of the Stevens brake will have the most tendency to draw nearly in a line with the king-bolt under the circumstances named?

A. Not one more than another. In the Stevens brake the line of draft is direct between the windlasses, I believe, crossing the central line of the car about at the centre of the car.

Int. 36. Will you state whether you can illustrate by another diagram sheet the comparative variations of the truck levers of the Springfield brake and the Tanner brake, when the brake is applied to a car on a straight track, and the car then passes from a straight track on to a curved track of a radius of 800 feet, and vice versa? And if you can, please do so.

1346 A. That is the same illustration which I made in regard to the Springfield brake and the Tanner brake with the greater curvatures upon the first diagram sheet; and I have had drawn here, side by side, the Tanner brake and the Springfield brake, upon a curve with a radius of 800 feet, as nearly as it could well be done. The comparative character of the two brakes will be the same, whether the curve be large or small, but, of course, the difference will be less, because the variation is less when the radius of the curve is large. I do not mean that it will be less in proportion, but I mean that the difference will be less, because the variation of each car is less. In both of the diagrams here now for the first time presented the scale is one inch to the foot, instead

of half an inch to the foot. The proportions of the cars are represented here substantially the same that they were in the other drawing, and in both these diagrams the trucks of the cars are represented as swivelled about to the extent due to the curve of the track; both the same. It will be seen by a comparison of these diagrams that the swivelling of the truck produces a variation, geometrically, in the Springfield car substantially in a right line with the connections; while the same variation of the swivelling of the truck in the Tanner contrivance is substantially at right angles to the lines of the brake connections; so that, whatever variation there may be in the Springfield car by the swivelling of the truck requires that the connections should vary equal in amount to the variation due to the swivelling. In the Tanner brake—the way the proportions are drawn here—this amount of variation will make the short leg of a triangle, instead of being communicated directly to the connections; so that, if the variation due to the swivelling of the truck be half an inch at each truck in the Springfield car, the whole change of relative position of the ends of the truck levers to which the connections are ap-
plied will be one inch, and the greatest geometrical change which
1347 can be made in the Tanner contrivance under the conditions sup-
posed will be equal to the difference in length between the points *a*, *b*, *c*, and the points *a*, *e*, *c*, when added together, in both instances. The difference from *e* to *b* will be just the same as the actual change of length due to the swivelling between the points *e*, *f*, and also between the points *e*, *g*, respectively. This is the geometrical effect in the Tanner contrivance and in the Springfield contrivance; but in the Springfield contrivance the movement, being directly in the line of connection, is absolutely communicated to the parts so as to produce a greater tension of the connections, while in the Tanner contrivance the floating of the truck lever will destroy what geometrical difference the diagram exhibits, as I have explained, and the brake connection will not be perceptibly tighter than it would upon a straight line.

Int. 37. Can you state what will be the amount in inches of the variation of the truck levers in the Springfield brake under the circumstances represented in this diagram sheet?

A. I believe a more perfect solution of the problem can be obtained by a proposition in the plain rule of three than can be shown by these diagrams made upon this scale. It is not in the nature of these diagrams to afford accurate measurements when they are upon a small scale, but figures will not lie. If the proposition is suitably put down, then the result can be obtained exactly by the figures. It is obvious that in the running of the truck of a car upon the curve of a railroad a radial line, when drawn so as to pass through the king-bolts of the trucks, will be parallel to the axles of the driving-wheels if the car is properly constructed. It is also obvious that if a radial line be drawn between the two king-bolts, at equal distances from them, that line will be at right angles to the body of the car. Now, suppose that a radial line is repre-
sented by the dotted line *g h*, passing through the king-bolts of
1348 one of the trucks, and another radial line is represented by the
dotted line *i j*, and that the dotted line *k l* represents a radial line through the centre of the body of the car, at equal distances from each king-bolt. Now, it is obvious that these several radial lines will all come together at the same point. And again, if a line be drawn from centre to centre of the king-bolts, it will cut the radial line *k l* at right angles at *m*. Now, supposing *n* to represent a centre to which the sweep of the track is concentric, where these several radial lines come together, then the three points, *m*, *n*, and *o*, at one of the king-bolts,

will be a right-angled triangle. And the distance between the axes of the king-bolts, according to these diagrams, is about 37 feet; so that the distance from *m* to *o*, which is the distance from the centre of the car to one king-bolt, will be about 18½ feet. Now, the two radial lines *k l* and *g h* and the lines *m o* form, altogether, as I have said before, a right-angled triangle—the line *o h* to *n* being the hypothenuse, the line *m l* to *n* being the long leg of the triangle, and the line *m o* the short leg of the triangle. Now, taking the distance from *m* to *n* as the radius of the curve, which will be sufficiently near, then that line will be 800 feet; so that the lines *o g* to *n* and the lines *m k* to *n* converge 18½ feet in 800 feet; or, what is the same thing, they diverge 18½ feet in 800 feet. Now, going out from the king-bolt at *o* to the connecting-rod at *p*, the distance, as represented by this drawing, will be two feet and a quarter. It is obvious that, in going this two feet and a quarter, the lines *m k* to *n* and *o j* to *n* will diverge in the same proportion through that distance. So that it is a fair proposition to say that if, in going 800 feet, these lines diverge 18½ feet, how far will they diverge in going two feet and a quarter? Taking these three terms and finding the fourth, that fourth will represent substantially the variation in the connecting-rods which go from the 1349 windlass to the brake levers upon each truck, for it will be substantially the same at the other end of the car as it is at the end of the car where I have made the line *g*, *h*, only it will be in the opposite direction. This leaves out of view some change of angle in the connecting rods, which will be considerable on the short connecting rod in the Springfield car—showing the reason why there is more variation than in the other of the connecting rods; the shorter one showing the greatest variation because, in swivelling, it not only shortens, but changes the angle of the line of connection considerably upon the short connecting chain. And then the proposition will stand as follows: 800 : 18.5 : : 2.25 : *x*. Then *x* will represent the change of tension in the connecting rod due to the swivelling of one truck, and there will be substantially the same change in the other truck; so that 2*x* will represent the variation of difference between the points of the levers upon the swivelling trucks, when they pass from a straight line on to a curve, and vice versa. Now the variation, according to this formula, will be .62375 of an inch, for one truck, and the same for the other truck, making, for the variation of both trucks, twice that—namely, 1.24750, or about an inch and a quarter.

Int. 38. This being the amount of variation for a car with the Springfield brake upon it properly adjusted for a straight track, when with the brake applied in a proper manner upon such straight track it passes on to a curve of 800 feet radius, how material will said amount of variation be in respect of its effect upon the brakes of a car, and what, in your judgment, will be the result upon the wheels of the car?

A. If the brakes are set as tight as they can be set upon a straight line without sliding the wheels, and then the car be run on to a curved track of a radius of 800 feet, the wheels of one of the trucks will slide, of course, and the wheels of the other truck will be considerably 1350 loosened under the pressure of the brakes. I understand that the windlasses upon this Springfield car are about an inch and a half in diameter, (meaning by "windlass" the barrels upon which the chain winds); and this will be in proper proportion to a windlass of three inches on the Tanner brake—when the connections are made to the central lever half way between the ends of the levers and the fulcrum. Now a windlass an inch and a half in diameter will be about 4.7 inches in circumference and the amount of variation which I said would be due to the trucks, if multiplied by 7½, would be about equal to the circumference of the drum or barrel upon which the chain was wound in the Springfield car. And if we divide 360 degrees by 7½, we get 48 degrees, so that the variation in the swivelling of the truck will be equal to about 48 degrees in the revolution of the windlass, which is something over one-eighth of a revolution; and the variation of the other truck would be the same; so that, both together, the variation of the two trucks would be equal to 96 degrees, which is six degrees more than one quarter of a revolution of the windlass wheel.

Int. 39. But I understand you that under the same circumstances the Tanner brake would not be perceptibly affected?

A. It would not.

Int. 40. In one of your answers some time since you spoke of the fact that in the Tanner brake there is greater power applied to one pair of wheels in each truck than there is to the other pair in the same truck. Please state why this is, and whether or not there is in this respect any difference between the Tanner brake and the Hodge brake.

A. This is because the brake levers having three pivots—one at the lower end of the brake attached to one brake beam, the next one above
the lower end of the brake attached to the other brake beam, and
1351 the top of the lever is jointed to the connecting rod—the power
applied to each of these brakes is in proportion to the length of this brake lever—from the connecting point at the top hole to the bottom hole for one arm of the lever—when compared with the distance between the hole at the bottom and the next hole above it for the other arm of the lever; while for the other pair of shoes, the long arm of the lever stops at the hole between the upper and lower end of the lever—the other arm of the lever being the same as it was before; and therefore the variation of the power will be as the variation of the distance from the top hole to the central hole—as compared with the distance from the top hole to the lower hole—when put in relation to the distance between the central hole and the bottom hole, which is always common to both. So that if the brake lever be 36 inches long from centre to centre of the outer holes, and six inches long from centre to centre of the two lower holes or fulcrums, then if 100 pounds be applied to the top of the lever, the effect produced upon the brake beam connected with the lower hole will be 400 pounds; the effect upon the other will be 500 pounds.

The Tanner brake and the Hodge brake both contain this difference between the two pairs of wheels in each truck.

Int. 41. Going now to the Tanner brake and the Springfield brake, please state which of these two brakes requires the most power to be exerted by the brakeman at the brake wheel to convey a given amount of force to the brakes, assuming that the diameter of the windlass wheels, and of the part of the windlass shafts on which the chain winds, and the long and short arms of the brake levers, are the same in each brake, and that in the Tanner brake the connections from the windlasses to the centre lever are at the ends of the centre lever, and the connections from the centre lever to the truck levers are ten inches from the end of said centre lever, and that the centre lever is four feet long.

1352 A. The Springfield brake.

Int. 42. How much more power?

A. The proportion is as 16 on the Springfield brake to 24 on the Tanner brake, so that if 100 pounds be applied to the windlass of the Springfield brake, of course just 100 pounds will be exerted upon the brake levers, because the connection is direct. But in the Tanner brake the connection is not direct—it is through a centre lever having a long arm in that centre lever 24 inches, and a short arm 14 inches; so that if the same amount, to wit, 100 pounds, were applied to the windlass, it would communicate to the ends of the truck levers 171 pounds and a fraction; in both cases one-half the amount going to each truck.

Int. 43. Now compare the Springfield brake with the Hodge brake as to this point, assuming the same data as in the next preceding question but one, but assuming that the connections of the Hodge brake are made as they ordinarily are.

A. In the Hodge brake, if 100 pounds be applied to the windlass, the same number of pounds will be applied to each of the brake levers—so that there will be 200 pounds applied to the two brakes in the Hodge contrivance, when there are only 100 pounds in the Springfield brake. In all these calculations, I leave out the friction.

Int. 44. Now taking the Tanner and the Hodge brakes, assume that the leverage is made the same in each brake, and that both brakes are properly adjusted and in order; what, if anything, will be the difference between the two, in respect of their power to hold the car when the brakes are applied?

A. There will be no difference that I know of; but if the leverage be made equal, the connection between the truck levers and the central lever of the car body must be just half way between the connection of that central lever with the windlasses and the pivot of that central lever upon the body of the car.

1353 Int. 45. In view, then, of all the facts you have herein stated, what, in your judgment, constitutes the advantage possessed by the Hodge brake over the Tanner?

A. The advantage of the Hodge brake over the Tanner consists in the fact that there is no relative adjustment to be maintained in the brake connections. The levers used in the Hodge contrivance between the windlasses and the brake levers having no connection with the body of the car, float into the position required so as always to produce an equal strain upon each of the two trucks when the brakes are set up. This will not be the case in the Tanner brake unless the connections from the centre lever to the truck levers are adjusted to a suitable length—the one with the other. In consequence of this difference, the Hodge brake will bear much greater neglect of adjustment than the Tanner brake.

Int. 46. And I understand that you find no other difference between the two brakes than this?

A. I know of no other important difference between them.

Int. 47. At page 196 of the Defendants' Accounting Record in this case, it has been testified by M'r Robert Hitchcock that "a brake applied as now seen in Defendants' Exhibit Large Tanner brake" (which he had stated was the same as applied in the Patent Office model—meaning the Patent Office model of the Batchelder and Thompson invention,) "would not be a practical operative brake as applied to a railroad car"; and said Hitchcock further testifies, on the same page, that the reason of this is that "it applied too much power, and required the use of too much chain." Will you please state whether or not there are any, and if any, what, means of rendering the brake operative notwithstanding the thing referred to in said answer?

A. If the windlass in the Tanner brake be made proportionately too small for the leverage obtained by means of the central lever, then
1354 the brake may be faulty, because there will be danger of the brakeman applying too much power; but there is no difficulty in the Tanner contrivance arising from increasing the leverage upon the centre lever, provided the size of the windlass be proportionately in-

creased—the windlass wheel always remaining the same in both cases. By "windlass" I mean that part upon which the windlass-chain winds.

Int. 48. In connection with this subject, please look at the drawing of the Tanner patent and state what the six holes in the centre lever—three on each side of the centre-pin—indicate.

A. I understand them to indicate that the connection of that central lever with the truck levers can be made at different points, according to the judgment of the constructor.

Int. 49. Is there anything in the specification of the Tanner patent to limit the constructor to any particular point of attachment of the truck lever connections?

A. There is not.

Int. 50. At page 188 of said Defendants' Accounting Record, the same M'r Hitchcock testifies to a certain experiment as follows: "We took a car with the Tanner brake applied the same as on Exhibit 123. We went to a point marked by a bridge, using 120 pounds steam-pressure. We had a brakeman, a helper, and myself. We attained the highest speed that we could in running a certain distance which was marked by a switch; we estimated the speed at twenty-five miles an hour. At this switch we sounded the whistle; the brakeman was at his post, the man ready to draw the pin simultaneously, and the brake was applied—first with the Tanner brake as it now stands in that exhibit. We ran, I do not know how many feet, but we marked the place where we
1355 stopped. We then converted the brake into what is termed the old single brake, by disconnecting the lever of one truck from the centre lever. We went over the ground again, all things being equal, and stopped very nearly in the same place; I think we passed about somewhere in the neighborhood of the length of the car further. We were surprised ourselves in one sense; and we tried the experiment again in the same way, with just about the same results. We then coupled it up, making the Tanner brake good again, and went over the ground once more. The same instructions were given to the brakeman in each case, and all the conditions the same, and about the same results were obtained that we did with the first trial of the Tanner brake."

He also says, page 189, "the law of generating friction is as the pressure, not as the surface pressed on," and that in the said experiment "when operated as a single brake, the wheels slid a little ways. The brakeman was a common man, not acquainted with applying brakes. All that he could do was to exhaust his force upon the windlass. If he had, at the point where the wheels began to slide, let up on his chain, I think that the result would have been the same as with the Tanner brake, or nearer than it was. I became satisfied that if a man exhausts his force upon a single brake and does not slide the wheels, he does just as much service as he does when he exhausts his force under the same conditions on the double brake, not sliding the wheels."

Please state your views of this experiment, and give your reasons for your answer.

A. I do not see anything delusive in this. It appears to me
1356 that, taken as a whole, there is no delusion in it. If I understand him, he says that in a certain experiment, using both trucks, using the same brakeman, and as nearly as might be the same power applied to the windlass—a car was brought up in about the same time; and he says the law of generating friction is as the pressure, not as the surface pressed on. That is correct. He says further: "I became satisfied that if a man exhausts his force upon a single brake and does not slide the wheels, he does just as much service as he does when he exhausts his

force under the same conditions on the double brake, not sliding the wheels." I think that is correct. But it is clear that if this brake was so arranged that he could not slide the wheels of a single truck upon a car when applying it, when it was applied to both trucks the pressure upon each truck was only half what it ought to be. In other words, if the same pressure had been applied to the brakes in each truck in one case that was applied to the single truck in the other case, then the car would have been brought up in a little more than half the distance when using both brakes.

Int. 51. You say "in a little more than half the distance." Please state the reason why it would not be brought up in half the distance.

A. The reason why it would not be brought up in half the distance is because the friction of the journals upon their boxes is in addition to the brakes in braking up a car, and a large part of that friction is due to the weight upon the car. This is independent of the brakes, and the further the car runs the more there will be of this friction; so that in order to bring up the car it would have to run more than half the distance, because the friction upon the journals due to the weight upon the car would only be used the distance the car run, and not the whole distance run in the first instance referred to when only one truck was used. So that if there was any delusion on the part of M'r
1357 Hitchcock, it was in supposing that this was a fair test, going to show anything instructive in relation to the braking up of a train of cars; for if it proved anything, it proved that one truck in a train of cars was enough to have brakes upon it, leaving all the other trucks to go without any brake; because if one brake is as good as two for the purpose of bringing up a train of cars, then it is as good as four or sixteen, or any other number, which is simply absurd.

Int. 52. At page 189 of said Defendants' Accounting Record, the same M'r Hitchcock is questioned and answers as follows:

"Q. In applying friction to car-wheels for the purpose of stopping the car, are the wheels ever made to slide when the car is at high speed?

"A. No, sir; that is impossible.

"Q. When do they, if ever, slide?

"A. When the car is nearly at rest."

Please state the views entertained by you on this subject.

A. I do not consider it impossible to slide the wheels of a car when the train is going rapidly, and it certainly is not possible to slide the wheels of a car when the train is not going at all. There is something in this idea of M'r Hitchcock's, which is not all a mistake. It is more difficult to bring the brake-shoes to hold tightly upon the car-wheels when they are turning rapidly. I think, with the same amount of strain upon the brakes, the shoes will not hold as much when the car is in rapid motion as they will when it slows its motion somewhat. If the shoes be put on tight enough, the wheels can be slid at any rate of motion; there is no doubt about that. I have said in the course of this examination that the bite of the wheels upon the rails was the only available force to be employed for bringing up a train—the same as it is the only available force to be employed for putting a train in motion;
1358 the difference being that in bringing up a train it is usual to use the wheels of the cars, while in putting a train in motion it is usual to use the wheels of the locomotive. Now, if it is true that the wheels will not hold well upon the rails when they are sliding, it is just as true that the brake-shoes will not hold as well upon the wheels when they are moving as they will when they are at rest; and therefore,

everything else being equal, the less the rate of revolution of the wheels, the tighter the brake-shoes will hold—or in other words the more they will act to retard the revolution of the wheels. But it is always necessary, in order to brake up a train, that the shoes should be put upon the wheels when they are in motion, because when they are not in motion the train is not in motion. I recollect that in the early working of the Western Railroad, as was then reported, a freight-train in going down the steep grade into Springfield had not upon it sufficient brakemen to hold it, and it ran away in spite of the brakes; whereupon the engineer reversed his engine and put on so much power as to run his wheels in the opposite direction, and it was then reported that this train went down under those conditions, went across the street, through the shops of the company, and some portions of it, I believe, into the river. Now, it is more than likely that this same engine could have drawn that train up that grade, but it could not hold it from going down, in addition to the brakes which were upon it. It was because the engineer put absolutely too much steam upon his machine in the first instance, and then kept it on there—thereby destroying the bite of the wheels upon the rails to a very great extent, jumping off himself, as well as I remember, and leaving the train to go down. Now, it is likely if this engineer had had the necessary presence of mind to have let the steam more gradually into his cylinders, maintaining the bite of the driving-wheels upon the rails, he might,
1359 in doing that, in addition to what the brakes could do, have held
that train. So this braking up of a train is a mixed problem. But notwithstanding that, it is undoubtedly an axiomatic fact that in order to bring up a train of cars in the least possible distance, it is necessary to put the brakes upon every wheel in that train, and not only to put them on, but to keep them on with such an amount of pressure as shall come as nearly as possible to sliding the wheels on the rails—without sliding them.

Int. 53. At page 189 of Defendants' said Accounting Record, the same M'r Hitchcock was asked and answered as follows:

"Q. You will now please look at 'Defendants' Exhibit Large Tanner brake 123,' and wind up the larger windlass until the scales in each truck indicate 48 pounds, and set down the dog in the ratchet. [Witness did as directed.] You will now take 'Exhibit round scale' and apply it to the periphery of the wheel, and state how many pounds it takes to lift the dog from the ratchet.

"A. Two pounds.

"Q. You will now disconnect one of the truck-levers from the centre lever, thereby resolving the brake into a single brake, and turn up the smaller or twelve-inch windlass wheel until it indicates 48 pounds in the truck to which the windlass is attached. [Witness complied with the request.] You will now apply to the periphery of said wheel 'Exhibit round scale' and state how many pounds it takes to relieve the dog in the ratchet.

"Two pounds.

"Q. What conclusion do you deduce from the facts elicited by the two experiments?

"A. That the power transmitted through a 16-inch wheel upon
1360 a double brake is equal to the power transmitted through a 12-
inch wheel to a single brake.

"Q. Then is it proper or not to conclude that no more power can be conveyed to a single truck by a 12-inch wheel than to the brakes of two trucks by a 16-inch wheel?

"A. It is proper."

Please state whether you have recently been at Springfield, Mass., and there seen the exhibit referred to in this quotation, and whether you have with said exhibit made a test to ascertain how many pounds were required to lift the dog from the ratchet, and if you have, state whether the answers in said quotation given by said Hitchcock as to the number of pounds are correct, and state what was the result you obtained in said test, and give your reasons for your answer.

A. I have been to Springfield, and there saw an exhibit which I was told to be—and which I suppose was—the same as the one upon which M'r Hitchcock says he made the experiment. I tried that experiment myself upon the model. I did not obtain the same results which M'r Hitchcock says he did. My recollection of it amounts to this: that with the small wheel, the power necessary to actually move the windlass in its journals was something considerably over two pounds, and with the large wheel something considerably less than two pounds—which ought to be true, provided the journals of the windlasses—and the windlasses—of the two are equal and alike, which I believe they are. If they are equal, it is, in my judgment, absurd to suppose that double the result will be produced with the large wheel that can be produced with the small one, the wheels being comparatively of the sizes mentioned. If one wheel were as large again as the other, then it might be and should be true, without a doubt. I found upon trial with that contrivance that it was quite easy to be deceived in regard to it. I found that if
1361 the wheel was first pulled with the steelyards so as to move, the steelyards might afterward be let off considerably before the windlass would retreat under the pressure of the springs below—in both windlasses; and that it was quite easy to hold the windlasses at a state of rest, the round scale marking two pounds in both cases. This is because it takes a great deal more power where friction is involved to produce a movement of the parts than it takes to hold the parts in place when the movement has been produced. It will be readily understood that the matter of friction involved is to be added in one case and subtracted in the other. That is, when the movement is to be produced, the power required must be sufficient to overcome the opposing power and move the parts—added together; but when it is simply to hold the thing in position, the friction may be subtracted from the opposing power, and still the parts remain in position. So that the scales may mark in the two cases a difference equal to double the amount of the friction, and in this case all that variation might be produced, and still the dogs which hold the ratchet would be loose in both cases. I think it is in that way the mistake was made.

Int. 54. You have said that if one wheel were as large again as the other, you would get double the result. Please explain this more fully.

A. I do not know any way to explain it. It is like the proposition that two and two make four. It is very difficult to explain how I know it; I know it is so. If I understand M'r Hitchcock, he says that in one case he put upon the windlass of the truck 48 pounds upon one scale and 48 pounds upon another—which makes 96. In the other case, he put upon the windlass 48 pounds only. Now, it is perfectly obvious that in order to move the 96 pounds by means of a lever applied to the windlass in one case, and to move 48 pounds by means of a lever applied
1362 to the same windlass in the other case—the power applied to the lever being equal—he requires a lever twice as long in one case as he does in the other. There is no doubt about that.

Int. 55. Is it, then, or not, proper to conclude—as M'r Hitchcock does—

that no more power can be conveyed to a single truck by a twelve-inch wheel than to the brakes of two trucks by a sixteen-inch wheel?

A. I don't know whether it is proper for M'r Hitchcock or not; it is not proper for me, because I know better.

Int. 56. It has been testified by several of the defendants' witnesses in said Defendants' Accounting Record, that some months ago a car, having upon it the Tanner brake, and also a car having upon it the Springfield brake, were put in the same train on the Boston and Albany Railroad, running from Boston to Albany—the Tanner brake-car being the rear car of the train one day and the Springfield brake car being the rear car the next day; that the brake-shoes of these two cars were made of, as nearly as could be, the same metal, were cast from the same puddle of iron, were of the same pattern, and were put on new at the same time; and that when these brake-shoes were worn out, the respective sets of them were weighed and it was found that the loss of metal from wear with the Tanner brake-shoes was 76 pounds, and with the Springfield brake-shoes 77 pounds.

Please state whether or not in your judgment these alleged facts prove anything in reference to whether the two brakes had operated during the period of the experiment in an equally efficient manner, and give your reasons for such answer as you may make.

A. I do not think it proves anything as to the efficiency of the brakes. It would be quite easy to produce the same amount of wear, using the brakes in one case uniformly upon both the trucks, and in the other case using the brakes first upon one truck and then upon the other, alter-
nately; but when using them upon one truck only, putting them
1363 on with considerable more power than when using them upon two
trucks.

Int. 57. When you were at Springfield did you observe the large models there known in this accounting as "Defendants' Exhibit Large Tanner brake 123," and "Defendants' Exhibit Large Springfield brake 124"? and, if you did, state whether those models were, in your judgment, correct and fair representations, in all respects, of the devices they purport to show; and if not, state why not.

A. I suppose I saw the models inquired of. One of them, as I understand it, was the same one we have just been talking about—on which the scales were used; the other one, as I understand it, was made to represent the Springfield brake. They were not, either of them, correct models in all respects. In the model representing the Tanner brake, the connection from the central lever to the truck-levers was not the same as described in the Tanner patent; and in the Springfield brake, the connection from the truck-levers to the windlass is not the same as was in the old Springfield brake. The windlass in the model representing the Springfield brake, is not located in the same relative position that it was in the car having on it the Springfield brake.

Int. 58. What effect, in the use of the Springfield brake, would be produced by placing the windlass upon an actual car in the same relative position that it is in said model?

A. The effect would be to modify a grave fault which exists in the Springfield brake.

Int. 59. What is the fault to which you refer?

A. The variation of the brake connections by the swivelling of the trucks. And another effect would be to bring the windlass so as to interfere with the passage-way through a train of cars, fore and aft.

Int. 60. Would, then, placing the windlass as it is in said model be admissible in a passenger-car designed for use?

1364 A. It would not.

Int. 61. You have said that in the defendants' Tanner model the connections from the centre-lever to the truck-levers are not made as in the patent. Please state in what respect they differ.

A. In the different position of the ends of the truck-levers to which the brake-rods are pivoted. In the Batchelder and Thompson or Tanner brake patent, the end of each truck-lever—where the connecting rod is jointed to it—is nearly in a line between the king-bolt and the point to which that same connecting-rod is jointed to the central lever of the car. In the model it is very much to one side of that line, so as actually to produce a difficulty in the swivelling of the truck which would not exist when constructed according to the description in the patent.

Int. 62. And would this difficulty which would exist in a brake constructed and arranged like said model tend to an unequal application of the brakes when a car, having the brakes applied, passed from a straight track on to a curve?

A. It would.

Int. 63. If, however, the combination and arrangement of the levers of the brake were as represented and described in the Tanner patent, so that the draft from the centre lever to the truck-levers was nearly or quite in a line with the king-bolts of the swivelling-trucks, would there be any inequality upon the trucks when the car, with the brakes applied, passed from a straight track on to a curve, and vice versa?

A. No appreciable inequality would take place in that case.

Int. 64. In respect of this matter of equality of pressure as between the trucks of the car, is there or not any difference between the Tanner brake, when constructed and arranged as represented in the patent, and the Hodge brake?

A. No appreciable difference, when the Tanner brake is in order.
1365 It is more difficult to keep it in good working order than it is to keep the Hodge brake in good working order.

Int. 65. In securing this equality of pressure as between the two trucks in the Tanner brake, what office do the tops of the truck levers perform?

A. They float sideways, so as to accommodate themselves to the line in which the connecting rods will draw between the king-bolts and the points upon the central lever to which the connecting rods are pivoted.

Int. 66. It has been testified in this accounting record, on the part of the defendants, that the brake represented in "Defendants' Exhibit old tender brake" has for many years been in use upon the tenders of locomotives upon the Western Railroad—now the Boston and Albany Railroad. Please state whether you understand the form of Springfield brake known in this case as the tender brake? And if yea, state what, if any, bearing the use of said brake on locomotive tenders has upon the question of the value of the form of Springfield brake which has been referred to in your deposition as used upon passenger and other long cars.

A. I believe I understand that tender brake. I believe it is substantially the same brake as was on the old Springfield car which has been testified to. But I don't think it has much bearing upon the value of that brake when used upon long cars—because the tender is a very short car, and a passenger-car is a very long car, for one reason; and this difficulty which exists in the Springfield brake is very much greater in a long car than it is in a short one—everything else being equal. Another reason is, that upon tenders a brake is not much used, while upon passenger-cars it is or should be always used whenever it is desirable to brake up a train.

Int. 67. Please state which brake—the Springfield brake or the Tanner brake—contains the most parts requiring adjustment?

1366 A. The Springfield brake—twice as many, without going into particulars. There are two pairs of connecting rods to adjust in unison in the Springfield brake, and only one pair in the Tanner brake.

Int. 68. Which has the most parts requiring adjustment—the Springfield brake or the Hodge and the Stevens brakes?

A. The Springfield brake.

Int. 69. Which brake—the Springfield or the Tanner—requires the most nicety of adjustment, and why?

A. The Springfield brake—for the reason that there is between the windlasses and their connections with the truck levers no intermediate lever, while in the Tanner brake there is an intermediate lever—which may yield somewhat to the variation of strains upon the brakes.

Int. 70. Does the presence of this intermediate lever in the Tanner brake impart to that brake considerable elasticity in use, as compared with the Springfield brake?

A. If you mean by "considerable" that it is better for that elasticity, I should say yes. That lever is not, and should not be, very much elastic.

Int. 71. Is there or not any elasticity to speak of in the Springfield brake? And if not, why not?

A. There is none between the windlasses and the truck levers, because the rods pull in a right line. All the elasticity that can be there is what may take place by the flopping of the rods up and down.

Int. 72. You have spoken in this deposition of the effect upon the Springfield brake when a car with the brake applied passes from a straight track onto a curve, and vice versa. Will you state what effect this action of the brake, under these circumstances, would naturally have upon its action when used on straight tracks?

A. It tends to disturb the adjustment; because if the brakes
1367 are drawn as tight as they should be upon a straight line, and
then the car passes upon a curve, so as to draw the connections considerably tighter, the tendency is to displace the parts in some way—either by bending the levers, or by forcing some other part about the car to yield. And it also tends to wear the shoes more than it should wear them—provided the wheels do not take to sliding. If they do take to sliding, it tends to destroy, to a great extent, the braking power of the car, and also to the spoiling of the wheels.

Int. 73. It has been testified in this accounting record that a brakeman, when setting the Springfield brake, "felt a sharp yank," and that "the brake-wheel went right away from him and threw him against the car railing." Please state what, in your judgment, would in the Springfield brake tend to produce such an effect as this.

A. Passing from a straight line to a curve, before the dog was brought to bear upon the ratchet so as to hold the windlass.

HERVEY WATERS.

Cross-examination waived.

Deposition of Edward Lang, taken at Boston, Sept. 24, 1872.

Direct examination by M'r Sayles:

Int. 1. What is your name, age, residence, and occupation?

A. Edward Lang. Age 47. Residence Boston. Occupation, car-inspector on the Boston and Providence Railroad.

Int. 2. How long have you been car-inspector on the Boston and Providence Railroad?

1368 A. I have worked there since 1847, and have been car inspector since 1854.

Int. 3. Has the Springfield brake been put on some of the cars of the Boston and Providence Railroad within the last six or eight months?

A. It has.

Int. 4. And the Tanner brake also put on a car?

A. Yes, sir.

Int. 5. How many cars have had the Springfield brake put on them?

A. Two.

Int. 6. What are the numbers of those cars?

A. 40 and 12.

Int. 7. How many have had the Tanner brake?

A. One.

Int. 8. What is the number of that car?

A. 10.

Int. 9. Whose duty is it to keep these cars in order, and see that the brakes are adjusted properly?

A. That is my business.

Int. 10. How often has it been necessary to adjust the brakes on these three cars you have mentioned?

A. Well, the Springfield brake requires to be adjusted about every day; the brakemen say so much about it I have to look at it. I should think the other—the Tanner brake—not quite so often; perhaps twice a week. Since these brakes have been put on, we have had more talks about adjusting than we had with the Hodge brake, usually.

Int. 11. Which of the brakes—the Springfield or the Tanner brake—requires the most adjusting—that is, which requires the most labor to adjust it each time it is adjusted?

A. The Springfield brake, for the reason that they have double rods. They have two rods on each truck, whereas the Tanner has one.

Int. 12. Which of the two brakes requires the nicest adjustment?

1369 A. Well, for that reason, the Springfield brake does.

Int. 13. You spoke of there being complaints about the brakes being adjusted, &c. How often, since these brakes have been on that train, have you heard complaints about their not working well?

A. Almost every day, every time I saw the brakemen, which is about every day. They wanted them taken off as soon as possible. [I told them if they wanted them taken off they must go to the superintendent. I had no power to do that. All I was put there for was to keep the cars in good running order, adjust the brakes, &c.]

Int. 14. What has been the nature of their complaints?

A. Well, that they couldn't stop the train.

Int. 15. And you say these complaints have occurred almost every day since these brakes have been on the cars?

A. Yes, sir.

Int. 16. How long have they been on the cars?

A. Well, I should say, though I don't seem to remember much about it, I should say about four months.

Int. 17. A number of months, any way?

A. Yes, sir.

Int. 18. Have you recently measured the levers in these three cars?

A. I have. I measured them the latter part of last week.

Int. 19. What is the length of the truck-levers on these three cars, No. 40, No. 12, and No. 10?

A. The whole length of the levers on one of the cars with the Springfield brake is 34 inches, and also the Tanner; and I find that on the other car with the Springfield brake the long arms of the truck-levers are three-quarters of an inch longer. The lower fulcrum is six inches from centre to centre, and then I measured the upper one 28 inches more.

1370 Int. 20. You say, then, that on one of the Springfield brake cars, the levers are just the same as they are in the Tanner brake?

A. Yes, sir.

Int. 21. What do you think would be the effect, supposing all of the cars on the Boston and Providence Railroad that have the double brakes on now, had on the Springfield brakes?

A. Well, it don't seem as though we could get along. I suppose we might, but it would be pretty hard work to get along so without braking our cars. We should have to have more help, certainly, to keep the brakes in order. As brakes are now, I suppose it is almost impossible to think of getting along with a brake like that, because the Hodge brakes are so much better.

Int. 22. Has the business of the Boston and Providence Railroad increased very much during the last few years?

A. Well, it has increased double within the last ten years certain, and perhaps thribled, or more, since I have been there, according to the number of cars. We have got three or four times as many as we had when I first went there.

Cross-examination by M'r Whipple:

Cr. 1. At the time the Springfield brake was put upon two cars of the Boston and Providence Railroad, was there also a Tanner brake put upon one car?

A. Yes, sir.

Cr. 2. Thereafter did you hear any complaint from the brakemen as to the operation of the Tanner brake in holding the car?

A. Well, those two brakes on those cars were spoken of. All that was said to me was, that they didn't like them so well as they did the Hodge brake, the old brake that had been on the cars that was taken off; the brake that these replaced.

1371 Cr. 3. Did the brakemen give any preference to the Tanner brake over the Springfield brake?

A. Well, I haven't inquired of them with regard to the two brakes. They would simply come to me and want to know how long those brakes were going to stay on, and I would tell them I didn't know anything about it. I hadn't anything to do about their being put on.

Cr. 4. Did they complain as much about the Tanner brake as they did about the Springfield?

A. There wasn't any particular brake spoken about.

Cr. 5. Then, if I understand you, the complaint was as much against the Tanner as the Springfield?

A. Well, all they said was, they wanted to know how long before those brakes were going to be taken off. I never questioned a brakeman with regard to his preference for either brake, so I can't say what their preferences were.

Cr. 6. Then, if I understand you, the complaint was quite as general against one as the other. Was it or not?

A. Well, that is all I have to say. They spoke about those brakes on the cars, and wanted to know when they were going to be taken off.

Cr. 7. Did they mean by "those brakes" the Tanner and Springfield brakes?

A. The brakes that were on those cars, both of them.

Cr. 8. What cars? Give the numbers.

A. 10, 12, and 40.

Redirect by M'r Sayles:

Int. 23. Was the Tanner brake used on all or nearly all of your passenger-trains a number of years ago, and for a number of years?

A. When I first went to work for the company, some of the 1372 cars had the Tanner brake on. We put the Tanner brake first on those cars that we used most. We used a single brake. I have used a single brake myself. And afterwards that was connected with the Tanner brake. That was the best thing I ever saw to connect the brakes together.

Int. 24. Do you know about what year the Tanner brake was put on the cars?

A. Well, I can't say how many cars had the Tanner brake on when I first went there, but I should say in 1847. I probably helped to put the Tanner brake on some of the cars.

Int. 25. And after that it was put on all the passenger-cars?

A. Yes, sir. The Tanner brake was all the brake we had in those days.

Int. 26. And about how long was it continued on the road?

A. Well, five or six years after that; somewhere along there, as near as I could judge. I can't tell near enough to make any positive statement about it.

Int. 27. Was it continued on until the company adopted the use of the Hodge brakes?

A. Yes, sir. That is the brake we took off and put the Hodge on.

Int. 28. When the Tanner brake was in use on that road, did it work well?

A. Well, we didn't have any fault found with it that I know of. I don't remember of any. It required a little nicer adjustment than the Hodge. The brake used to hold well enough. For that reason we used to have to adjust it a little nicer than we do the Hodge.

Int. 29. But with that exception, it used to hold well enough?

A. Yes, sir. We didn't know anything different in those days.

1373 Recross by M'r Whipple:

Cr. 9. Was there ever applied to the passenger-cars of the Boston and Providence Railroad a brake which operated both trucks by means of a revolving shaft upon which pulleys were attached, with grooves in them?

A. Yes, sir.

Cr. 10. To what extent was that brake applied to passenger-cars on that road?

A. Well, we had it on, I guess, perhaps half our cars at one time. There was a man by the name of Miller, who was a pattern-maker for M'r Griggs, who suggested that idea. But we found in going round curves it twisted the shaft and threw it out of order. It was almost impossible to keep it in order for that reason.

Cr. 11. Was this brake applied to the passenger-cars of that road before the Tanner brake or single centre lever brake was applied?

A. No, sir; the Tanner brake was the first.

Cr. 12. How long after the Tanner brake was applied, in 1847, did ou apply the brake spoken of in the previous question?

A. Well, four or five years after that. I should say five years.

Cr. 13. Have the tenders of the locomotives on the Boston and Providence Railroad double trucks?

A. No, sir; I think we have a few tenders with double trucks, but as a general thing there are six wheels under the tenders.

Cr. 14. On those that have double trucks, are the brakes operated through a revolving shaft with wheels on the same?

A. I can't say with regard to that. I don't know much about their tenders. I have very little cause to do much with them, unless they
break a chain or something of that kind, over in town, and then I
1374 have it repaired for them. I know they used to put that revolving
shaft under their tenders, and used it later than they did under their passenger-cars.

Cr. 15. Did they use this revolving shaft under the passenger-cars until they substituted the Hodge brake?

A. There might have been cars there with that on when we adopted the Hodge brake.

Cr. 16. Then for a time the cars were equipped either with the Tanner brake or with this revolving-shaft brake, were they?

A. Yes, sir.

Cr. 17. And finally both gave place to the Hodge brake?

A. Yes, sir.

Redirect by M'r Sayles:

Int. 30. Are you certain that any of these revolving-shaft brakes were on the cars up to the time the Hodge brake was adopted?

A. Well, I couldn't say, but I think there were.

Int. 31. Which was the best brake, the revolving-shaft brake or the Tanner brake, for passenger cars?

A. I do not consider the revolving-shaft brake a practical brake now, because we have discovered that we cannot get round a curve with it; it would disarrange it. But it was on the road some little time before I discovered it. I found the brakes were disarranged—for what cause I couldn't tell, until I perceived that those shafts, which had been made square, were twisted. What I mean to say is, we had some shafts made round and some square, and with a round shaft you couldn't see so easily that it was twisted as you could with a square one. Come to inquire into it, I found that was the trouble. In going round a curve, something had to give; either the chain would break or the shaft twist. The in-
ference would be, of course, that the Miller brake would not an-
1375 swer, for that reason. I consider the Tanner brake the best, for
that reason. Going round a curve, that would disarrange.

Int. 32. What do you mean by "that?"

A. The Miller brake, of course.

Recross by M'r Whipple:

Cr. 18. How sharp a curve did it require the car to be run round in order to disarrange the Miller brake?

A. I can't say about that. Almost any curve where the brakemen applied the brake on the curve.

Cr. 19. Are there any sharp curves, so called, on the Boston and Providence Railroad where brakes are applied on the main line?

A. I can't say. I am not well enough acquainted with the road to know where their curves are. A brakeman is liable to set a brake on any curve, if there is anything in the way—if he is called to do so.

Cr. 20. Was the twist of the shaft in the Miller brake due to an excessive strain by the application of power from the brake-wheel?

A. Well, I don't know how to answer that question any more than to say that a man couldn't twist it on a straight track. If he should apply it on a curve, the curve would help him to twist it. His strength would not be enough to twist it on a straight track, but when he went round the curve and applied it he would have so much more power.

Cr. 21. What month in the year 1847 did you commence work on the Boston and Providence road?

A. The 19th day of October.

Cr. 22. At that time you found the single centre lever or Tanner brake in use on cars of that road, did you?

A. I think I did.

1376 Cr. 23. Any doubt in your mind about it?

A. No doubt.

Cr. 24. How many cars compose the train in which the cars having the Springfield brake and the Tanner brake on are run?

A. Five.

Cr. 25. What brakes are on the other two cars?

A. The Hodge.

Cr. 26. How often do you have to put new shoes on cars having the Springfield brake and Tanner brake on?

A. Well, sir, I can't say as they have ever had any new shoes put on.

Cr. 27. Has neither the Springfield brake nor the Tanner brake come to shoeing since it was run on the road?

A. I can't say. I haven't paid any particular attention to that matter, and have not looked at it.

Cr. 28. Do you apply the shoes to cars when they need them?

A. Yes, sir.

Cr. 29. And you have no recollection of applying any new shoes to either the Springfield brake or the Tanner brake since they were put on?

A. No, sir; I don't put the shoes on myself. I have too much to do to put shoes on. My men do that, and that is a matter I should not be likely to know much about—that is, unless I paid particular attention.

Cr. 30. So you know nothing about the shoeing of either of the brakes?

A. No, sir.

Cr. 31. How many cars should you judge had the Tanner brake on in October, 1847, when you came on to the Boston and Providence road?

A. It would be almost impossible for me to look back and think. I can't tell anything about it. I was young in those days in railroading.

1377 Cr. 32. How many, according to your best recollection?

A. We didn't have but very few cars then. I can't say how many cars we had. I should say—my best recollection would be—perhaps a dozen.

Cr. 33. What was the weight of cars at the time the Tanner brake and Miller brake were used on that road compared with the weight at the present time?

A. Well, according to my judgment, perhaps cars are a third heavier now than they were then, and perhaps some of them are more than that.

Cr. 34. Are they not, as a general rule, more than as heavy again?

A. I think our sleeping-cars are. Our sleeping-cars are the heaviest cars we have got. But we had some long cars in those days that held seventy-six passengers, and then we had short cars that held sixty, as we have now. We don't use the cars that hold seventy-six passengers much now; we have only one or two, I think, that we keep as spare cars.

Cr. 35. Was the centre-lever and Miller brake applied to those heavy cars?

A. I have no recollection about that; I can't say.

Cr. 36. Who were the brakemen who complained to you about the Tanner brake and the Springfield brake?

A. Well, M'r Rogers is the man who came to me individually and spoke about their being taken off.

Cr. 37. What did he expect to be put on in place of them, if they were taken off?

A. The Hodge brake.

Cr. 38. Are you applying the Westinghouse air-brake to the cars of that road?

A. Yes, sir; putting it on all the cars.

Cr. 39. Was it not for the purpose of getting that on these cars that he wanted the Springfield and Tanner brakes taken off?

1378 A. No, sir; merely the Hodge brake put back the way it was before. That probably will come in time when the superintendent orders it on.

Cr. 40. How long since M'r Rogers requested you to take them off?

A. Since the trial at Springfield. He said it was all over now, and he supposed there was no further use for them; but I told him I couldn't do anything about it until I had orders.

Redirect by M'r Sayles:

Int. 33. You speak of "the trial at Springfield;" what do you mean by that?

A. Well, after he came from Springfield he called it the trial; I don't know what it was; but after he came from Springfield he said it was all over, and he supposed they didn't want the brakes on any longer, and he wanted them shifted.

Int. 34. Had he been to Springfield?

A. Well, I supposed so by that; yes, sir.

Int. 35. What had he been to Springfield for; did you learn?

A. No, sir, I did not; I don't remember; something in regard to the brakes.

Int. 36. About how long ago was it that he said this to you about the trial at Springfield?

A. Well, say a fortnight. That is just merely my judgment; I don't profess to tell dates exactly.

Int. 37. Might it not have been some time in August when he spoke about the trial being over at Springfield?

A. I can't say. I know it was after he came from there that he spoke about it. It is now the 24th of September. It might have been in August or might have been in September—the first of September; I have no recollection. I shouldn't want to state definitely the time.

Int. 38. You say it was after he returned from Springfield?

1379 A. Yes, sir; that is all I can say. It was after he returned from Springfield.

(Deposition read to the witness.)

Int. 39. Do you authorize the reporter to sign your deposition?

A. Yes, sir.

EDWARD LANG.

Deposition of E. L. Wallace, taken at Boston Oct. 12, 1872.

Direct examination by M'r Sayles in person:

Int. 1. Please state your name, age, residence, and occupation.

A. E. L. Wallace; age, 36; residence, Boston; occupation, locomotive engineer on the Boston and Albany Railroad, Worcester division.

Int. 2. How long have you been engaged in railroading, and in what capacities?

A. Twenty years. I commenced first working in the shop; then fireman; then engineer.

Int. 3. About how long were you fireman, and for whom did you fire?

A. Well, I fired for different ones, but I fired for M'r Hobart on the express-train the longest. I fired for him about five years.

Int. 4. While you were fireman for M'r Hobart do you remember of a peculiar kind of brake being put on to the New York line cars, called the Springfield brake?

A. Well, I don't recollect the name of the brake. I didn't know it
was called the Springfield brake until you were speaking about
1380 it; but I recollect the circumstance about a brake being bought
by M'r Twichell and put on there. [Answer read.] Oh, I made
a mistake there.

Int. 5. Just state what correction you wish to make.

A. Well, these Springfield brakes that the Western road put on we were all afraid of when we had them on; and in case of a flag or any accident happening to us we were all afraid of the train. We couldn't stop the train. Well, we would run—I won't state how far, but so that we couldn't stop. We had to reverse the engine and do all in our power to stop it.

Int. 6. You speak of M'r Twichell's buying a brake. Was it before this brake that you speak of that you couldn't stop a train with was used, or after, that M'r Twichell bought the brake?

A. After.

Int. 7. About how long was this brake that you say you were afraid of, that you couldn't stop a train with, used?

A. It was used about a year, I think.

Int. 8. What was it you spoke of that M'r Twichell bought the right to use?

A. I heard that M'r Twichell bought the right to use it on the Western road, that is, between Springfield and Worcester—that is, the Hodge brake. After we got them we were safe.

Int. 9. What brake was used on the Boston line cars before and after this brake that you were afraid of was used?

A. I don't recollect.

Int. 10. Was it the same one you used afterwards?

A. I think it was.

Int. 11. What train were you fireman on at the time these Springfield brakes were used?

A. The morning express, which left Boston at half past eight.

Int. 12. Boston and New York express?

1381 A. Boston and New York express.

Int. 13. About how long ago were these Springfield brakes used on the Boston express line cars?

A. I can't state positively, but I think in the year 1856 or 1857.

Int. 14. How long have you been engineer on the Boston and Albany Railroad?

A. Fourteen years.

Int. 15. And what train are you running now?

A. The three o'clock Boston and New York and Albany express.

Int. 16. While using the Hodge brakes, was there any difficulty in making your stops at stations?

A. No, sir.

Int. 17. What position did M'r Twitchell occupy on the road at the time he bought the Hodge brake for the Western road, as you have stated?

A. He was president of the Boston and Worcester Railroad. He took Judge Hopkins' place, I believe.

Int. 18. Were the Springfield brakes taken off and the Hodge brakes put on soon after M'r Twitchell bought the right of Hodge?

A. I believe they were.

Int. 19. Will you authorize the reporter to sign your name to your deposition?

A. Yes, sir.

E. L. WALLACE.

Deposition of Oramel A. Brigham, taken at Boston, Oct. 12, 1872.

Direct examination by M'r Sayles in person:

Int. 1. Will you state your name, age, residence, and occupation.

A. Oramel A. Brigham; age, 41; residence, Lowell; occupation, depot-master on the Boston and Lowell Railroad, at Lowell.

1382 Int. 2. Do you or not have charge of the cars at Lowell?

A. I do.

Int. 3. Do you remember of the Sringfield brake having been put on a train of cars on that road some months ago?

A. I do.

Int. 4. Are they still used on the cars on that train?

A. That I can hardly tell, the cars are changed so. Those cars have been in the shop and perhaps the brake has been taken off. The cars have been in the paint-shop, and when they go in there they stay for some time, so we have not had our regular cars. I can't swear whether they are off or on. My impression is that they are not on.

Int. 5. You think, then, they have been taken off?

A. I do.

Int. 6. Did you run as conductor on that train at all while those brakes were on?

A. I did.

Int. 7. While you ran as conductor on that train, how did the Springfield brakes work in stopping the trains?

A. They did not work well. We ran by the stations.

Int. 8. Did or not the brakemen complain very much of their not working well?

A. They did.

Int. 9. Did you or not often hear the brakemen who ran on that train complain of them; all the time while those brakes were used on that train?

A. I did, with the exception of when they had been adjusted; and that did not last but a short time.

Int. 10. What do you mean by the short time that they were adjusted?

A. What I mean is, that the adjustment did not last but a short time.

1383 Int. 11. (By M'r Whipple.) Then they worked well, so far as you know, while they were adjusted?

A. While they were adjusted they worked very well.

Int. 12. (By M'r Sayles.) Do you remember a trial of a week to see what stops could be made on the road with those brakes?

A. I do.

Int. 13. How often during that week were the brakes adjusted?

A. That is what I do not know.

Int. 14. What did you learn at the time with regard to their being adjusted that week?

A. I had the impression that they were adjusted at Boston here every time they came in at the car-house.

Int. 15. (By M'r Whipple.) You don't know anything about it?

A. I can't testify to that positively, sir.

Int. 16. Is it merely your impression?

A. That is it.

Int. 17. (By M'r Sayles.) Did you learn so from those who were on the train at the trial—the conductor or brakemen?

A. I heard the brakemen speaking of it. (Defendants objected as hearsay.) As I said before, I know nothing of it that is positive at all.

Int. 18. You mean by that you did not see it done?

A. I did not see it done. I don't want to testify to anything I don't know is so, because we have got men enough who know it.

Int. 19. Did you mean, when you spoke of the brakes being adjusted, during that week that that trial was?

A. No, sir; I did not mean that. It was when the brakes got to working bad; they couldn't hold the cars with them; and they
1384 would complain of it to the master mechanic, and have him go and set the brakes up, or adjust them.

Int. 20. You said they would not stay adjusted long?

A. No; they proved they didn't.

Int. 21. Who were the brakemen on this train when you were conductor on it?

A. George B. Granger and M'r Wing, the same man you had out at Springfield. Alpheus Wing, I think his name is.

Int. 22. (By M'r Whipple.) Did you understand that M'r Sayles had Alpheus Wing out at Springfield as a witness?

A. No; I mean the man who was out there. I don't mean to say that M'r Sayles had him out there, because that I don't know anything about.

Int. 23. (By M'r Sayles.) At the time of this week's trial of these Springfield brakes, who were the brakemen on the train?

A. Alpheus Wing and John D. Emerson.

Int. 24. Were they regular brakemen at that time?

A. No, sir.

Int. 25. How did they come to be on that train during that trial?

A. Because they were Blood's old brakemen previous to this, and were put on there because they were good brakemen.

Int. 26. (By M'r Whipple.) They had operated the Springfield brake before?

A. They had broke with this same brake for a long time. They had been Blood's brakemen for a long time.

Int. 27. (By M'r Sayles.) Who ordered them to go there and brake during that week's trial?

A. That is what I don't know positively, as I never saw any order.

Int. 28. Was braking their regular business at this time?

A. Not at this time.

1385 Int. 29. Had they, or not, been promoted some time before this—one as conductor and the other as assistant depot-master?

A. Yes, sir; both of them.

Int. 30. And had been acting in their new capacities for some time before this trial of a week?

A. I think so.

Int. 31. Who would have been the right one to order them from their positions to brake on that train?

A. M'r Winslow, the superintendent.

Int. 32. Do you know whether it was understood that this trial was to be made and the result proved in this case by M'r Blood and the brakemen?

A. I never knew what the trial was made for at the time the trial was made; and at the time they went to Springfield I did not know what they were going for. I knew they were going to testify in this case, but what for I didn't know.

Int. 33. Was it understood that they were to go and testify in this case before this trial was made of a week?

A. I think it was.

Int. 34. When you were conductor, did you, or not, notice that the brakemen worked very much harder in applying these Springfield brakes than when they were applying the Hodge brake?

A. I did.

Int. 35. And they would then often run by the stations, would they not?

A. They would.

Int. 36. Did they often run by the stations when they had the Hodge brake on?

A. No, sir. But at the same time the boys would say, if the brake was adjusted they could hold them.

Int. 37. Were the brakes generally out of adjustment?

A. I think they were.

1386 Int. 38. On the whole, did you consider the Springfield brake a safe and reliable brake for railroad purposes?

A. I do not know enough about brakes to answer that question strictly.

Int. 39. It is only your opinion that is asked for?

A. I do not consider it as safe a brake as the Hodge brake.

Int. 40. With the experience you have had on railroads, all I want to know is whether you consider that a safe and reliable brake for fast passenger-trains?

A. I do, if they are well adjusted. I make that answer because we proved, when they were on that trial, that they could stop the train, and I know that train runs as fast as any train we run.

Int. 41. Take the brakes in the condition in which they generally were while you were running on that train, did you consider them safe and reliable?

A. Well, if we did not consider them so we should not have run them on the train, I suppose.

Int. 42. About how long is it since they discontinued the use of those brakes?

A. I don't know. We never had them on any train, that I know of, except that Blood's train. I don't think those brakes have been used since the trial—not much of any. I don't think they have, but I don't state that as a thing that I know.

Int. 43. Would M'r Wing and M'r Emerson have acted as brakemen on that train during that week's trial without an order from M'r Winslow, the superintendent?

A. They would have acted as brakemen by an order from the depot-master here, M'r Piper; but M'r Piper would have had his orders from M'r Winslow, so that really it came from him, I suppose.

O. A. BRIGHAM.

1387 *Deposition of A. G. Batchelder, taken at Boston, Oct.* 12, 1872.

Direct examination by M'r Sayles in person:

Int. 1. What is your name, age, residence, and occupation?

A. My name is A. G. Batchelder; age, 52; residence, Lowell; occupation, manufacturer.

Int. 2. Are you one of the inventors of what is called the Tanner patent car-brake?

A. I am.

Int. 3. Soon after you invented this brake, did you or not apply the brake to a car or cars on any railroads in Massachusetts? If so, on what roads, and when?

A. I applied it on a car on the Fitchburg Railroad, in October, 1847, and also on the Lowell and Boston Railroad, in Lowell, in June, 1848.

Int. 4. Where did you locate the truck-levers when you applied the brake to these two cars you speak of?

A. I placed it inside the truck frame, back of the king-bolt—placed upright, so that the top of the lever would vibrate either way.

Cross-examination by M'r Whipple:

Cr. 1. How many cars did you apply this brake to on the Lowell road?

A. One.

Cr. 2. How long was that in use on that car?

A. I believe they ran it until some time in the fall of the same year.

Cr. 3. How long did they run the car on which you put the brake on the Fitchburg road with said brake?

A. Well, I don't know of my personal knowledge—only what I was told by M'r Thompson, one of the inventors. He had charge of it after I put it on.

1388 Cr. 4. What did he tell you?

A. Well, it was some time after. He told me he ordered it off by some misunderstanding or something—some trouble he had with some of the men on the road.

Cr. 5. Then you did not put it on, if I understand you, yourself?

A. I did.

Cr. 6. Did you give up the charge of the brake thereafter to M'r Thompson?

A. I did—on that road. He was living there at the time.

Cr. 7. Are you pecuniarily interested at the present time in the Tanner brake patent, so called?

A. I suppose I am.

Cr. 8. To what extent?

A. I have a certain interest in the extension.

Cr. 9. How large an interest?

A. I don't know as that has anything to do with this case.

Cr. 10. Do you refuse to answer the question?

A. If it is essential to the testimony in this case, I will answer it.

Cr. 11. Have you a half interest?

A. That is bordering on my refusal.

Cr. 12. Have you a quarter interest?

A. That is the same.

Cr. 13. Have you a tenth interest?

A. That is also the same.

Cr. 14. Have you any interest at all?

A. I have.

Cr. 15. On what other roads did you apply the so-called Tanner brake, besides the Lowell and the Fitchburg?

A. Not any.

Cr. 16. What you have already stated constituted your entire efforts in the way of introducing the same on railroads?

1389 A. I made some other efforts, as I have testified, in the beginning of this suit.

Cr. 17. What efforts; please name them?

A. I believe they are in print.

Cr. 18. If they are, please repeat them?

A. Well, I consider it introduced itself, after I made those trials. It soon found its way on other roads, as I found, by seeing them on those cars, I suppose. I had no reason to believe that it got on the cars in any other way than by seeing them on these that I put them on to.

Cr. 19. Then, if I understand you, the putting of the brake upon one car on the Fitchburg road and one upon the Lowell road constituted the sum and substance of your efforts to introduce the brake to the attention of railroad companies?

A. Well, we did a good many things; all we supposed we could do, or that it was possible for us to do at that time.

Cr. 20. Well, what things did you do more than is stated in the question?

A. Well, we employed others to get it introduced.

Cr. 21. Who were they?

A. Well, M'r Heath and D'r Bellows.

Cr. 22. What did these men do towards introducing it?

A. Our greatest trial was to get a patent out during all this time; therefore, we didn't probably try as hard as we should if we had had a patent.

Cr. 23. Then there was nothing done in the way of introducing it until you got a patent, other than you have already named, on the Fitchburg and Lowell roads; is that so?

A. Nothing that I remember of in particular.

Cr. 24. And even on those roads it was used but a short time; is that so?

A. On the Lowell road they used it until it was ordered to be
1390 taken off by M'r Winslow in order to put on some other kind of
brake. It was a spare car.

Cr. 25. What other kind took the place of it?

A. M'r Hodge's.

Cr. 26. Do you consider the Hodge brake a better brake than the Tanner brake?

A. I consider it an improvement.

Cr. 27. In that sense, do you mean that it is a better brake for operating a car, or holding the same?

A. I do not consider that it would hold a car any better—no further than it equalizes the force on the wheels—than the Tanner brake.

Redirect by M'r Sayles in person:

Int. 5. Did you travel on M'r Blood's train while the Springfield brakes were used; and, if so, about how often?

A. I made several trips to Boston on his train during April, May, and June, 1872.

Int. 6. When did you first know the Springfield brake on that train?

A. Somewhere about the middle of April.

Int. 7. Did you notice how the train was stopped at the stations?

A. I took notice that they usually ran the length of them by the stations; not every time, but a great many times.

[Int. 8. Did you or not hear the conductor or brakemen speak of the Springfield brakes, whether they worked well or badly, at any time?

A. I have heard the conductor, M'r Blood, speak of them several times. Up to the week's trial that he had, he always spoke against them.

Int. 9. Please state what you heard him say with regard to the Springfield brakes.

1391 A. He couldn't see why they were using that kind of a brake, when it was not so good as the Hodge brake. He didn't see into it. He thought that they could not get up the power that they got with the Hodge brake.

Int. 10. Did you or not hear him speak of those brakes a short time before the week's trial they had, to see what kind of stops they could make; if so, what did you hear him say?

A. On Saturday before the week of trial I talked with him concerning the brakes. He said he was having his train all adjusted right, and was going to make a week's trial of it for the purpose of seeing how good time they could make, or what it would do—I don't know the words he used, but that was the idea—for the purpose of testifying in the case.

Int. 11. Did he say where he was going to testify?

A. Springfield, Mass.

Int. 12. Did he at that time say what brakemen he was going to have?

A. He said he was going to put on his old brakemen, or have on his old brakemen.]

Int. 13. Have you often travelled on the train between Lowell and Boston when the Hodge brake was on?

A. I have.

Int. 14. Did you notice, when the Springfield brake was used, whether the brakemen worked as hard or harder than when they applied the Hodge brake?

A. Well, I have always noticed the working of the brakemen at the wheel, and I never saw them work as hard before as they did on the Springfield brake. Sometimes two of them would get hold of one wheel—one time, I noticed—in order to stop the train at a station.

A. G. BATCHELDER.

1392 *Deposition of Wesley R. Batchelder, taken at Boston, Oct.* 12, 1872.

Direct examination by M'r Sayles in person:

Int. 1. State your name, age, residence, and occupation.

A. My name is Wesley R. Batchelder; age, 29; residence, Lowell; occupation, clerk.

Int. 2. How often do you travel between Lowell and Boston?

A. Every day, down and back.

Int. 3. Have you ever traveled on conductor Blood's train since last October; if so, about how often?

A. From one to six times a week.

Int. 4. Did you know what brake was used on that train during this time?

A. I didn't know the name of it, or what it was called, until, I should say, the middle of June. I knew there was a different brake there from what had been, but I didn't know by what name it was called.

Int. 5. Did you notice the working of that brake?

A. I did.

Int. 6. How did it work in stopping the trains?

A. Well, sometimes it worked as well as any brake; at other times they would run by and back back. I don't think I ever saw it, though, more than five or six times when I was on the train.

Int. 7. You never saw it run back more than five or six times?

A. Back back more than five or six times.

Int. 8. Would they usually stop where they ought to at the stations, or run partially past the stations?

A. Yes; they would usually stop at the stations where they ought to. As I said before, it was only in a few instances that I saw that they did not stop. Not being a constant rider on that train, of course I
1393 didn't see the workings of it as much as I should if I had been.

Int. 9. Did you notice the brakemen's working on the train—whether they worked hard to apply the brakes, or as they did when they used the Hodge brake?

[A. I did in one instance, in particular, in the case of a brakeman, when I was in the smoking-car. He came in, and, as he sat down, he drew a long breath. I spoke to him and asked him if he was tired. He replied that he was. "These new brakes," was his expression, "are awful hard." I asked him what he meant by new brakes. He said there was a patent on the old brakes, for the use of which the owner had demanded a very large sum of money, and, as he understood it, the railroad company had put this on to show that they could use a brake and not pay him for his brake. I then told him, from seeing his hands so badly calloused—he could hardly open them straight or close them up tight. I think they were the worst calloused hands I ever saw. I suggested to him that he buy a pair of thick leather gloves, and a few days after that I saw him with the gloves on, and told him I was glad he had adopted my suggestion. He said, yes, he had, and thanked me for making the suggestion to him. In another instance, after this conversation with him, I asked M'r Emerson, the other brakeman, how they worked, and he replied that he was in the employ of the railroad and didn't want to say either way; that his bread and butter depended on his work, and if he didn't say anything he should not have anything to prove.

Int. 10. Did this brakeman say how his hands came to be so calloused?

1394 A. Well, because this brake was so much harder to operate—that was what he said.

Int. 11. Was this brakeman M'r Wing?

A. This brakeman was M'r Granger, who took M'r Emerson's place. M'r Emerson took Wing's place when he was promoted, about the first of July, and Granger was put on in Emerson's place. I had seen Granger on other trains. He was a spare brakeman before he was put on this train.

Int. 12. What, if anything, did you ever hear M'r Blood say about the working of these brakes?

A. I heard him—I should think it was late in the winter or early spring—he was in the depot, and the superintendent, M'r Winslow, and another gentleman stood there talking and pointing under the cars, and Blood soon stepped up to them and seemed quite excited, and I heard him make this remark: "I don't care a d—n. I have got just as good brakemen as there are in the world, and you give me a good brake and I will stop the train, if you will allow me the leverage of it, as quick with one hand as any man you can put on this train with this brake—I don't care if he weighs a ton"—meaning the brake they were growling about that was on the train at that time.

Int. 13. What brake was this they were growling about?

A. It was this brake which I afterwards found was called the Springfield brake.]

Int. 14. Who were the brakemen on this train at this time?

A. Wing and Emerson.

Int. 15. How long did they continue as brakemen on that train, if you know?

A. M'r Emerson was put on to the new train, as conductor,
1395 which leaves Lowell at five minutes past seven in the morning,
the last of May or first of June. I think that was put on about the last of May. The time-tables were changed about that time. Blood then run an express down, making only four stops, while Emerson's, five minutes later, was accommodation, and made all the stops, and they have so continued up to this time.

Int. 16. Do you know whether that Springfield brake is on that train now?

A. No, it is not, and has not been since about the middle of August.

Int. 17. What brake is on it?

A. The old Hodge brake.

Int. 18. On the same cars that had the other one on?

A. I am not positive about the baggage-car; but passenger-cars No. 1 and No. 2, and smoker No. 63 are Blood's regular cars; he has run those for a long, long while; but the baggage-car, which is No. 22—I don't know whether that had the Springfield brake on or not. That is the car that is running now and has been running for some time—three or four months.

Int. 19. While this Springfield brake was on Blood's train, were there any cars run in the train that had other brakes on; if so, what kind of brakes?

A. Blood left Lowell every morning at seven o'clock, and then ran to East Woburn, sixteen miles, and there attached two cars which came from Stoneham, and then ran two miles further to Winchester, and there attached four or five cars—almost always four—and brought them into Boston. At night he takes out those same cars, with the Hodge brake on (they always had the Hodge brake on) and drops them off where he takes them on in the morning, and then runs to Lowell with cars all
having the Springfield brake on. From East Woburn up, sixteen
1396 miles, after Emerson's train was put on in the morning, he had
no stop to make from Lowell until he got to East Woburn, where he put on the first Hodge brake.

[Int. 20. What was it that you say Blood seemed to be excited about?

A. I don't know. I came into the depot, and two gentlemen stood there, and Blood stood a little distance from them, and I should judge from the conversation that he had had something to say about it before, because he spoke right up again and made some remark. I didn't stop to listen to the conversation, but stopped a moment or two because I saw John was talking, and then stepped into a car and took my seat. I was conductor on the Concord and Lawrence road for a short time, and since that time I have noticed more about the cars than I ever noticed before in my life.

Int. 21. Did you ever hear M'r Blood say anything about these brakes on any other occasion?

A. I have heard him say that he has "blowed about them to the super." That is his expression.

Int. 22. Has he ever said anything to you as to whether he liked them or disliked them?

A. He has given me to understand a great many times in the early summer that he did not like them by any means.]

W. R. BATCHELDER.

Cross-examination waived.

1397 *Deposition of Charles Flagg, taken at Boston, Oct. 22, 1872.*

Direct examination by M'r Sayles:

Int. 1. Please state your name, age, residence, and occupation?

A. My name is Charles Flagg; age, 50; residence, Worcester; occupation, locomotive engineer on the Boston and Albany railroad.

Int. 2. How long have you been a locomotive engineer?

A. Eighteen years this fall.

Int. 3. How long in your judgment would it require to stop a train of four cars on a level road, where you had two first class brakemen and such brakes as have been used on the Boston and Worcester road for a number of years, and running 26 miles in an hour and five minutes, making say five stops? What in your judgment would be a fair average time of stopping from the time you shut off the steam until the train came to a stop?

A. Well, I should say, with a good rail and brakes in good order, they ought to stop in thirty seconds; it should not exceed that time. I should say that it ought to be done in that time, at any rate. That would be my judgment of the thing now.

Int. 4. Would it or not make a good deal of difference in stopping a train where it was understood there was a trial being made to see what stops could be made—in that case it is supposed that the brakemen would always be at their post? In that case would or not thirty seconds in your judgment be plenty of time to stop the train in on an average?

A. Well, I should say on an average they would do it, on a trial so.

1398 Int. 5. On the same road supposing they run the 26 miles in an hour and twelve minutes, making from thirteen to seventeen stops, what in your judgment would be a fair average time of stopping from the time steam was shut off until the train came to a stop?

A. Well I don't know. I should say, to make their time, they could not lose any more time in stopping. Still, they would have to use a little more speed. I suppose they would have to use a little more time to stop, and they would have to increase their speed.

Int. 6. The question is, how much time would be required for the stops in order to make the time?

A. I should think your speed would be enough faster to make ten seconds difference in your stops. You have got to make shorter stops; then you have got to stop quicker because you have got to run at a higher speed, and you have got to stop quicker, if you do it as quick as you did in the other case. The quicker you run, of course the longer it will take to stop.

Cross-examined by M'r Whipple:

Cr. 1. Do you wish to be understood that to the thirty seconds in a previous answer you would add ten seconds, making forty seconds—as your answer to the last question?

A. Well, I don't know but I might have made that a little different in this way; I don't know the exact thing; if you are going to increase the time according to the number of stops you make, you have not got to use any more time to stop. I don't know how it is—I haven't thought it over to know—as you figure—just in that way. I think you said an hour and five minutes in the first place to go 26 miles and make five stops. Now, if you are going in an hour and twelve minutes and make sixteen or seventeen stops, you are making twelve more stops in seven
1399 minutes more time. Well, you are not increasing your time a minute to a stop. That you can't do. You can't make a stop and start at any station in a minute. You must know that you can't stop a thing going forty miles an hour as quick as you can if it is going thirty, unless you run it against something that is solid—that won't move. That is the ground I go on. If it takes me thirty seconds to stop in going thirty miles an hour, if I have got to increase my speed ten miles an hour it will take me longer to stop.

Cr. 2. Do you mean by that that it takes ten seconds more added to the thirty?

A. No, I should not think it ought to take ten seconds exactly; but I think it would take five seconds certain.

Cr. 3. Which, added to thirty, makes thirty-five seconds?

A. Yes, sir.

CHARLES FLAGG.

Deposition of Wesley R. Batchelder (recalled), taken at Boston, Oct. 23, 1872.

Direct examination by M'r Cozzens:

Int. 1. Will you please state whether, since you were examined here on the 12th of October, 1872, you have become able to state any more accurately than you then did when it was that you first knew that the brake called the Springfield brake was on certain cars of M'r John C. Blood's train on the Boston and Lowell Railroad? If so, please state as nearly as you now can when it was.

A. It was the last of April this year, 1872—instead of the first of June that I first knew it.

1400 Int. 2. Over how long a period after this time—the last of April, 1872—did these trips which you made on M'r Blood's train while this Springfield brake was on any of the cars of that train extend?

A. From that time until the brakes were taken off—the middle of August, I think.

Int. 3. Did you go away on a vacation about this time; if so, when did you go away?

A. About the 1st of August, 1872, and returned about the middle of August; I can't state exactly the day. I don't think I saw them on the train but once after I returned. The next time I looked—the next time I went up over the road—they were all off.

Int. 4. Then the substantial period over which these trips extended was from the last of April until the time you went away on your vacation—the first of August—was it?

A. Yes, sir.

Int. 5. During this period what days in the week did you ride on said Blood's train?

A. Seldom any day except Saturdays—and that up in the afternoon at 4 o'clock.

Int. 6. Did you ride on said train every Saturday afternoon during that time, and if not, state the facts about it?

A. Almost always, with the exception of afternoons when I went to the matinees at the theatre. Then I could not catch that train and had to go later—on the five or six o'clock train.

Int. 7. Did these later trains have any Springfield brakes on them?

A. They did not.

Int. 8. Now deducting the Saturday afternoons when you went to the matinees during said period, about how many Saturday afternoons would it leave during the period that you went on Blood's train, as near as you are able to recollect?

A. I should say not over eight or ten times. I went very frequently then to the theatre—more frequently than I had before or have since.

1401 Int. 9. During these eight or ten times, at how many of them did you see said Blood's train that had the Springfield brakes on, run by stations when attempting to stop?

A. I should say some five or six times; so much so that I noticed it.

Int. 10. You said in your deposition here on the 12th of October that you travelled on Blood's train, since last October, as often as from once to six times a week. Please state how many weeks during this period you travelled on said train as often as six times a week.

A. Only one week—in the spring of 1872.

Int. 11. Can you state what part of the spring of 1872 this week was?

A. The very last of March or the very first of April.

Int. 12. Before you knew that the Springfield brake was on any of the cars of said Blood's train, how much attention, if any, had you paid to the working of the brakes on said train?

A. Comparatively none.

Int. 13. When on said Blood's train during the time before you knew that the Springfield brakes were on any of the cars of that train, what were you usually doing while riding in the cars?

A. Almost always reading.

Int. 14. You spoke in your deposition here on October 12th, about Emerson's train being put on in the morning, and then Blood had no stops to make from Lowell until he got to East Woburn where he put on the first Hodge brake. Do you recollect about when it was that Emerson's train was put on?

A. The very last of May or first of June, 1872. I think it was the last of May.

Int 15. After Emerson's train was so put on, how many stops would it leave for Blood's train—with the Springfield brake cars alone on it—at which you could notice the operation of the brakes in stopping?

1402 A. None in the morning. On the four o'clock train in the afternoon he was liable to stop five times, but seldom stopped more than four.

Int. 16. You mean, do you, seldom more than four when he had only the Springfield brake to rely upon?

A. I do. Of the eleven stops which he was liable to make going up from Boston to Lowell at four o'clock in the afternoon, only four or five would be made with the Springfield brake alone; the rest would be made with the help of the Hodge brake.

Cross-examined by M'r Whipple:

Cr. 1. How many feet, according to your judgment, did the train with the Springfield brake on run by the stations?

A. I should not have noticed it to have made any minute of it, unless the train had made a bad run by. What I mean by a bad run by is almost the whole length of the four cars that constitute the train with the Springfield brakes on it.

Cr. 2. Did the train invariably run by at each station?

A. These five or six times that I have reference to the rear car stopped where the first car ought to have stopped and usually did stop with the Hodge brake on.

Cr. 3. Did you ever know a train to run by the length of it with the Hodge brake?

A. Never.

Cr. 4. Did you ever know it to run by the length of one car?

A. Yes, I have.

Cr. 5. The length of two cars?

A. Not if it was fully understood that the train was to stop there.

Cr. 6. Does not that train run at a high speed?

A. Very.

1403 Cr. 7. Is there any train on the road that runs at a higher speed?

A. None, unless they are late.

Cr. 8. What should you judge to be the speed which the train must run in order to make its time?

A. I should judge that M'r Blood's four o'clock train out of Boston—between the stations at which he is liable to stop between Winchester and Lowell—ran at the rate of thirty miles an hour.

Cr. 9. In running this train is it necessary that very slow time should be made out of the city of Boston and into the city of Lowell?

A. They make very slow time until they get to Winchester.

Cr. 10. What is the distance from Boston?

A. Eight miles.

Cr. 11. And what is the time for the last mile in going to Lowell?

A. I can't state exactly the time. The last mile is from the Bleachery in, and they run there, I should say, at the rate of 18 to 20 miles an hour.

Cr. 12. From the lower to the upper station do you think they run at the rate of 18 or 20 miles an hour?

A. I am only speaking about coming up to the Middlesex street depot. Between the Merrimack street and Middlesex street depots I never go.

Cr. 13. The hour and five minutes, or the hour and twelve minutes, in which the time-table requires the trip to be made, you understand includes the starting at Boston and arriving at the Merrimack street depot in Lowell?

A. Yes, sir; I so understand.

Cr. 14. What should you judge to be the time in the city of Lowell between the two depots?

A. I go there so seldom I cannot state with any accuracy.

Cr. 15. It is very slow, is it not?

1404 A. The engine is detached, I should say, more than half way between the depots and the cars run in of their own accord, because they have to cross a street. It is all a level street going in after the engine is detached, but they have to cross this street and they go down at a pretty slow rate.

Cr. 16. Then whatever time is lost in getting out of Boston and getting into Lowell, to the Merrimack street depot, must be deducted from the hour and five minutes or the hour and twelve minutes, which constitutes the time of the train, must it not?

A. Yes, sir; I should think it would leave them about an hour to run it.

Cr. 17. Then would not the train, in your judgment, have to make more than thirty miles an hour between the stations, and between the two cities, in order to make the time and make the stops?

A. Not that train; no, sir; I don't think it would.

Cr. 18. Supposing it had to make 13 stops between Boston and Lowell, would not a higher speed be required between some of the stations than thirty miles an hour?

A. I don't think the train ever runs over thirty miles an hour.

Cr. 19. Did you ever time the train so as to determine accurately the speed?

A. I have; yes, sir.

Cr. 20. In what way?

A. By the watch.

Cr. 21. In what method by the watch?

A. By minutes and seconds.

Cr. 22. Well, what data did you have other than the minutes and seconds; you must have had some data to go by?

A. Well, when we would start from a station, or when we would pass a station—for instance we always pass Wilmington—I have noticed that, taken my watch in hand, and seen how long we have been in going
from one station to another. This was brought about by a con-
1405 troversy which I had in relation to the speed of trains, having no
reference to this case whatever.

Cr. 23. Did you take into account the number of miles from one station to the other?

A. Yes, sir.

Cr. 24. And then the time in which the train was passing over that distance?

A. Yes, sir.

Cr. 25. And you came to the conclusion that the average speed of that train is thirty miles an hour?

A. Yes, sir; after leaving all the Hodge brakes off. They run faster then. The average speed would be about thirty miles an hour.

Cr. 26. What was the speed of the train when the cars having the Hodge brake on were in it?

A. It takes us twenty minutes to go eight miles.

Cr. 27. Well, what would be the number of miles per hour at that rate?

A. Three times twenty are sixty, and eight times three are twenty-four.

Cr. 28. Well, how many miles per hour is it, as you figure it?

A. I should say that, at the rate they run out, it is about twenty-four miles an hour, if I am anything of a mathematician.

W. R. BATCHELDER.

Deposition of A. G. Batchelder (recalled), taken at Boston, Oct. 23, 1872.

Direct examination by M'r Cozzens:

Int. 1. Have you any correction to make in the testimony you gave here Oct. 12, 1872, in reference to the name of the person by whose order the Batchelder and Thompson brake was taken off of the Lowell Railroad, as you stated the other day? If so, please make it.

1406 A. I stated the other day that it was by the order of Superintendent Winslow. But on reflection, M'r Godfrey King told me that he had orders (that is the correct statement of it) to put on M'r Hodge's brake, and he would have to take off the Batchelder and Thompson brake from that car in order to put on the Hodge brake.

Int. 2. Was, then, the Batchelder and Thompson brake running on the Lowell road until the Hodge brake was ordered to be put on?

A. It was running up to that time.

Int. 3. About what time was it that the Hodge brake was ordered to be put on?

A. I think it was about the time that M'r Hodge took out his patent. It was in the fall of the year; the first of November, I think it was.

Int. 4. Which year was this? The year that you first put the Batchelder and Thompson brake on the Lowell road, or some other year?

A. I put it on in 1848; and this was at the time that Hodge received his patent. I don't know the date of his patent. I can't tell whether it was the same year or the next year. All I can judge by is by Hodge's patent. I know that Hodge was round himself assisting to put it on, for he called to see me at that time and told me about his patent.

Int. 5. Then, do you mean that the Batchelder and Thompson brake continued on the Lowell road from the time you put it on, as you stated the other day—in the summer of 1848—until soon after Hodge's patent was obtained and the Hodge brake was ordered to be put on?

A. Yes; that is what I mean to state.

Int. 6. Have you reflected on this subject with reference to arriving at this length of time, since you made your second cross-answer on your examination here, Oct. 12, 1872?

1407 A. I have. I was thinking it over going up to Lowell that same day. The circumstance that it was on the car at the time that Hodge came round with his, led me to think that I might have been mistaken whether it was the same year or the next year.

Int. 7. You stated, in your deposition of Oct. 12, 1872, that when you applied the Batchelder and Thompson brake on the Fitchburg road, in October, 1847, and on the Boston and Lowell road in the summer of 1848, you placed the truck-levers inside the truck frames, back of the king-bolt; and placed them upright, so that the top of the lever would vibrate either way. Please state what, with this arrangement, would be about the line of draft from the centre-lever to the truck-levers when the brake was applied.

A. Well, it would be nearly on a line with the body of the car when it stood on a straight track.

Int. 8. In this arrangement, how would the line of draft be with reference to the king-bolts of the car when the brake was applied?

A. It would be in a direct line with the king-bolts.

Cross-examined by M'r Whipple:

Cr. 1. From your best judgment, how many months was the Batchelder and Thompson brake on a car of the Boston and Lowell road before it was superseded by the Hodge brake?

A. Well, it might have been six months, and might have been a year and six months; but my impression is now that it was one year, and from June to November of the next year.

Cr. 2. Did M'r Godfrey King, the master mechanic at that time on the Boston and Lowell Railroad, think enough of the operation of the Batchelder and Thompson brake, during the time it was on that car, to wish to put it on any other cars of that road?

A. I presume he did. From what he said to me, he thought considerable of it, but they had no authority to put it on any cars at all.

1408 Cr. 3. Who was superintendent of that road at that time?

A. I don't know. I can't say now. I presume I knew at the time, but I don't recollect now.

Cr. 4. In the case of Thomas Sayles vs. The Philadelphia, Wilmington and Baltimore Railroad Company, did not Godfrey King testify that you put a Batchelder and Thompson brake on a car of the Boston and Lowell road, with the large thrust-rods, such as are seen in the Patent Office model filed in the office in June, 1847?

A. I believe he did; but he did not testify correctly. He was mistaken; because I put it on with my own hands, and know how it was put on.

A. G. BATCHELDER.

Deposition of Benjamin F. George, taken at Boston, October 23, 1872.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. My name is Benjamin F. George; my age is about forty; I reside at Nashua, New Hampshire; and my profession is that of a civil engineer.

Int. 2. About how many years have you been a civil engineer?

A. About twenty years.

Int. 3. Are you at the present time engaged as civil engineer on any railroad? If so, what railroad?

A. I am. I am engaged as principal assistant engineer of the Boston, Lowell and Nashua Railroad. In the absence of the chief engineer I act in his place.

Int. 4. How long have you been so engaged on that road?

1409 A. Going on six years.

Int. 5. Are you familiar with the degrees of curvature on the curves of said road? If so, please state the minimum degree of curvature of some of the curves on the Boston and Lowell road.

A. Yes, sir; I am. Not with all of them, however, but most of them. Such as I have had occasion to examine I have found to be in the vicinity of 2,865 feet radius, in the main line proper.

Int. 6. Can you mention the places where these curves are?

A. There is one at Somerville Centre, one at North Billerica, and one near the Woburn watering station. That is all that occur to me just at this moment.

Int. 7. Are these curves of 2,865 feet radius the sharpest curves on the main line between Boston and Lowell?

A. From East Cambridge to Boston we have a passenger track that is separate and distinct from the main line. On that there is a curve of one thousand feet radius, or 955 feet are the exact figures. With that exception those are the sharpest curves there are on the main line between Boston and Lowell. I know of none sharper.

Int. 8. Are you familiar with the radius of the curves which are usually formed when turn-outs are made from main tracks or elsewhere? If so, please state what is the usual or frequent radius of such curves.

A. Yes; I am somewhat familiar with them. In answer to the second part of the question I would say that our rule for the minimum radius is 500 feet from the mouth of the switch until we pass the rail on the main track.

Int. 9. Does this apply to turn-outs which run from the main line of the roads?

A. Yes; on our road.

Int. 10. You say the rule for the minimum radius is 500 feet.
1410 Please give us some idea how frequently curves on such turn-outs as inquired about are of 500 feet radius or in that vicinity.

A. I should say that more than half were 500 feet radius.

Int. 11. Will you please state how many feet are represented by one degree of curvature?

A. In round figures, 5,730 feet radius. That is not exact, however. The mathematical answer to that would be 5,729.69. We call it for practical purposes in our work 5,730 feet.

Int. 12. Then, if a curve is given you as a one-degree curve, does that mean a curve of 5,730 feet radius?

A. Yes, sir.

Int. 13. And if a curve be given you of two degrees or three degrees, how do you arrive at the number of feet of radius from those data?

A. Divide 5,730 by the degree of curvature.

Int. 14. That is, two or three in the case supposed?

A. Yes, sir.

Cross-examined by M'r Whipple:

Cr. 1. Are there any curves of 500 feet radius connecting the main tracks either in Boston or in Lowell over which passenger trains run?

A. Yes, sir.

Cr. 2. At what places?

A. At Lowell.

Cr. 3. Are there any in Boston?

A. There may be, but I do not think of any now.

BENJAMIN F. GEORGE.

1411 *Deposition of John McAlister, taken at Boston, October* 23, 1872.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. My name is John McAlister; I am about 25 years of age; residence, Boston Highlands; I am a car builder by trade.

Int. 2. Are you at present employed on any railroad; and, if so, on what railroad?

A. I am; on the Boston and Lowell Railroad.

Int. 3. About how long have you been employed on that road?

A. Very near three years.

Int. 4. What have been your duties on that road during those three years?

A. Most of the time in the shop building cars, and when they wanted any extra help up at the car-house I was sent up there to inspect cars.

Int. 5. What are your duties at the present time?

A. I am inspecting at the present time because the man broke his toe, I believe, and he is off, and I am to stay there for a while. I don't know how long.

Int. 6. Have you had a good deal of experience in inspecting cars when they come in on trains?

A. Yes, sir; not on this road alone, but on other roads.

Int. 7. What sort of things do you have to do when you look over cars?

A. I have to sound the wheels and look over the brakes and see if there are any bolts broke or loose; and if there is any broke or loose I tighten it up or repair it if I can.

Int. 8. What do you have to do with the brakes?

A. Take them up sometimes. If there is a nut loose on the
1412 bottom of the rod I have to tighten it up a little. Sometimes a
shoe will be loose, and I have to tighten that up.

Int. 9. Do you remember a train of cars known as John C. Blood's train, or Conductor Blood's train, on the Boston and Lowell Railroad, which had in it four cars having on them what is called the Springfield brake?

A. Yes, sir.

Int. 10. Do you remember a certain trial week during which that train with those four Springfield brake cars in it was run on said road?

A. Yes, sir.

Int. 11. During that trial week, who inspected or looked over the cars in that train that had the Springfield brakes when they came into the car house at Cambridge at this end of the road?

A. I did.

Int. 12. Did you have to adjust the Springfield brakes on those four cars during that trial week; and, if so, how often?

A. Every time they came in; that is, every time they came over into the car house. Of course, when they came into the depot I was not there to look after them.

Int. 13. You mean the car house at Cambridge?

A. Yes, sir.

Int. 14. During that trial week, how often did they come into that car house at Cambridge?

A. I don't think they came in there but once a day, and that in the morning.

Int. 15. How often do you say you adjusted them?

A. Once a day.

Int. 16. When they so came in in the morning?

A. Yes, sir.

Int. 17. About how much time did you sometimes have to spend during this trial week adjusting these Springfield brakes?

A. Well, if I knew how long that train was in I could tell.
1413 For some days—almost every day during that week—I was out
there from the time they came in until they went out.

Int. 18. You were at work adjusting all the time?

A. Yes, sir.

Int. 19. Can you give us some idea how long that would be sometimes?

A. About one hour and a half.

Int. 20. Did you have anybody helping you adjust these Springfield brakes during this time?

A. Yes, sir.

Int. 21. Did you when, as you have stated, you were adjusting those brakes all the time from the time the train came in until it went out, always get the adjustment finished?

A. No, sir.

Int. 22. At any of these times when you say you failed to complete the adjustment in time for the train to go out, did you have anybody helping you during part of the time?

A. Yes, sir.

Int. 23. You say you have been employed upon other roads—about how long have you been engaged in railroading?

A. About fifteen years.

Int. 24. What have been your duties in railroading during that time?

A. I have been firing. I have been engineering and car-building. I didn't go a great deal engineering, because I only ran a gravel train a little while. I was firing a few years.

Int. 25. Are you a practical car-builder?

A. Yes, sir.

Int. 26. Practically familiar with the business?

A. Yes, sir.

Int. 27. From what you saw of these Springfield brakes during the time they were on the Boston and Lowell Railroad, what is your opinion of them as a brake to be used on a railroad?

A. I think they are a very poor thing.

1414 Int. 28. Do you know about how many cars there are belonging to the Boston and Lowell Railroad that use the double brakes?

A. I know how many passenger cars we have got, I think, but I don't know the exact number of cars we have got on the railroad.

Int. 29. State the number as nearly as you can.

A. I think we have got 67 passenger cars. How many smoking cars and baggage cars there are I can't say. That is, running with passenger trains. I do not mean the freight trains.

Int. 30. Now suppose that all the cars belonging to the Boston and Lowell Railroad which run on passenger trains were equipped with the Springfield brake, how many men do you think it would take to adjust those brakes properly?

A. I should think it would take about fifteen or twenty.

Int. 31. How many men are there now employed on the Boston and Lowell Railroad inspecting and looking after the cars and adjusting the brakes?

A. We have only got three men, I believe, in the car house to look after the whole of the cars and adjust the brakes. Well, there is no adjusting at all to amount to anything. The most that we have to look after now is to look and see if there is anything broke on the train—to see if the wheels are not broke, or anything loose—and so on. They don't have to touch one of these other brakes once in a dog's age, without it is to put on a brake-shoe. If the brake-shoe is worn down a little, then we may have to take up a little of the slack.

Int. 32. What brake do you refer to when you say "these other brakes"?

A. The Hodge brake.

Int. 33. How often do you say you have to adjust the Hodge brake?

1415 A. We don't have to touch them any oftener than a shoe is worn down, and perhaps that won't be more than once in three months.

Int. 34. You say that three men do the whole duty of looking over the cars—inspecting them, and adjusting the brakes—on the Lowell road at the present time?

A. Yes, sir; and put in the wheels too.

Int. 35. What are the wages of yourself and the men who have this duty of inspecting and looking after the cars and adjusting the brakes?

A. I am getting $2.75 a day, and I think some of the other men are getting $2.50.

Int. 36. While these Springfield brakes were on this train of M'r Blood's, did you see any of the brakemen who ran on that train?

A. Yes, sir; I used to see both of them every morning.

Int. 37. Did you ever hear any complaints from these brakemen as to how the Springfield brakes worked on that train?

A. Yes, sir.

Int. 38. About how frequently did they complain?

A. Almost every morning when they came in unless it was during the trial trips, when they did not seem to find so much fault, because I kept them up as well as I could.

Int. 39. What do you mean by keeping them up?

A. Keeping the brakes adjusted as well as I could.

Int. 40. Are there any cars that run over the Boston and Lowell road which run beyond Lowell or Nashua?

A. Oh, yes; we have a number of cars that run up to Concord and way up to Montreal—Vermont Central cars. Then we have cars that run up to Winnipisseogee, and Plymouth, and Littleton.

Int. 41. Do you know about how many cars run through to Montreal?

A. Yes; I think there are four. I don't know exactly how
1416 many run through to Montreal. There are two Vermont Cen-
trals and two Pullman cars. I don't know whether they all run
to Montreal or not.

Int. 42. How many do you know of that run to Montreal?

A. I think there are only the two Pullman cars.

Int. 43. Are these Pullman cars sleeping cars?

A. Yes, sir; both of them are sleeping cars.

Int. 44. In your opinion, as a railroad man, how would the Springfield brake answer for cars that have to run as far as these sleeping cars do—namely, from Boston to Montreal?

A. I don't think they would answer very well.

Int. 45. Why not?

A. Because, by the time they had run up there and back again, they would have got pretty well shaken to pieces. I should not think there would be much of them left, the way those worked.

Int. 46. To what do you refer when you say "the way those worked"?

A. The Springfield brake that was on Blood's train—for sometimes when they got in the bolts on the connecting rod from one brake to another would be worked loose and be half-way out—almost all of them, sometimes.

Int. 47. Did you ever have any difficulty with these Springfield brakes on Blood's train in adjusting them so that they would operate equally?

A. Yes, sir; I couldn't do it.

Int. 48. Why couldn't you do it?

A. Well, that is something I couldn't see into hardly—why I couldn't do it. When I would tighten up one of the rods that run through the brake-beam to bring the shoe up to the wheel, in drawing up one I would perhaps draw up the other one too tight, and the other would not be tight enough, and that is the reason why I couldn't adjust them properly. Say one brake hung off from the wheels two inches and the other
half an inch, or an inch—when I tried to bring up the one farthest
1417 off as near up as the other one was, I would bring the one that
was nighest close up, and the other one would not be up close
enough.

Int. 49. How often did you have such a difficulty as this?

A. Well, as often as I had a mind to go to work at it to do it.

Int. 50. While this Springfield brake was on these cars, did you have occasion to put any new brake-beams into the cars?

A. No, sir; it would not break a brake-beam.

JOHN McALISTER.

Deposition of Julius P. Searle, taken at New Haven, Oct. 14, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. Julius P. Searle; 56; New Haven, Conn.; baggage master in depot at New Haven.

Q. 2. How long have you been engaged in railroading?

A. Twenty years and one-half.

Q. 3. In what capacities?

A. Most of the time stationed in New Haven; occasionally was in the habit—from 1853 to 1860—of running from Boston to New York in the baggage car, taking the place of regular baggage-master.

Q. 4. Do you recollect of a brake being put on the New York line cars about fifteen years ago called the Springfield brake?

A. Yes; about 1856 or 1857.

Q. 5. How did that Springfield brake work?

A. The brake didn't give very good satisfaction—wasn't considered reliable.

Q. 6. Was it, or not, considered a safe brake by the men on the train?

1418 A. It was not considered very safe. It caused considerable trouble to brakemen in bringing the cars to a stop.

Q. 7. About how long was this Springfield brake used on said line cars?

A. I should think about a year.

Q. 8. Did you run as baggage-master on the train some considerable time—while those brakes were in use—between New York and Boston?

A. I made several trips on the road while these brakes were in use, from New York to Boston.

Q. 9. Did you, or not, often run by stations when those brakes were used?

A. Could not say as to running by stations, but found difficulty as to bringing cars to a stop coming into depots with that brake.

Q. 10. Did you have occasion to switch cars with brakes on at depots?

A. No, sir; I had nothing to do with switching them.

Q. 11. What do you mean by finding "difficulty as to running into depots" with that brake?

A. Particularly the Springfield depot. Were in the habit of cutting the baggage car off above the crossing from the train, and let it run down to where the baggage car should stop. Used to run by sometimes, and had to back up, stopping the passenger cars above; also in going into the yard in New York; because the brake didn't always hold; couldn't rely upon it. Caused considerable trouble to employés; and a good deal was said about it by men on the train that operated the brakes.

Cross-examined by M'r Whipple:

Cr. 1. How many different engineers hauled the trains on the express line at that time?

1419 A. Four. One from Boston to Worcester, Worcester to Springfield, Springfield to New Haven, New Haven to New York.

Cr. 2. As a general rule, did the train come in on time at Worcester, Springfield, New Haven, and New York, when the Springfield brake was in use on said train?

A. Couldn't say; don't remember.

Cr. 3. Can you say that they did not come in on time?

A. I couldn't say that they did not come in on time from that cause; not positively.

Cr. 4. Do you think that, as a general rule, the trains arrived at these points on time?

A. I think occasionally, from that brake, the trains were in the habit of running by stations and backing up, so using up time. I don't think anything about it. I don't know, because it isn't clear to me; it's a long time ago. I know that we had a good deal of trouble with the brake.

Cr. 5. Is it clear to you that you had trouble with the brake?

A. Yes, sir.

Cr. 6. But it isn't clear to you that that train was run on time? Is that so?

A. I say a train might have run past a station by a bad brake and lost time, and still arrive at a station on time by making up the time.

Cr. 7. Did the train, as a general rule, arrive at stations on time?

A. I couldn't say.

Cr. 8. Do you think the officers of the New York and New Haven road, Springfield and Hartford, the Western road, and the Boston and Worcester Railroad, would run a train for more than a year on a fast express line with a brake thereon that was unreliable and unsafe?

A. I don't know.

Cr. 9. How long did they run this brake that you say is unreliable and unsafe?

1420 A. I think about one year is my answer.

Cr. 10. Do you think the officers of a railroad feel the responsibility of running a train safely, as much so as the employees of the road?

A. One brake to a car might stop a train when another would not work. There are other brakes as well as that which might be out of order. Sometimes a brake catches and throws men off. I think the officers do feel the responsibility.

Cr. 11. And yet you think they would run a train with brakes thereon which were unreliable and unsafe, do you?

A. I think they would not run a train with a brake that they considered unsafe.

Cr. 12. Did they run a train the brakes of which were said to be unsafe?

A. They ran a train with brakes said to be so by the employees. I don't know as the officers considered them unsafe.

JULIUS P. SEARLE.

Deposition of E. Upson, taken at New Haven, Oct. 14, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. E. Upson; 41; New Haven; baggage-master in depot at New Haven.

Q. 2. Were you ever brakeman on the New York and Boston line cars; if so, when and how long?

A. I was, about 15 years ago, for about two years.

Q. 3. What brakes were used on the Boston line cars while you were brakeman?

A. The Springfield brake.

Q. 4. About how long were those Springfield brakes used as near as you can remember?

1421 A. I couldn't tell exactly how long. I think one year. Might have been longer.

Q. 5. How did those Springfield brakes work?

A. Did not work very well.

Q. 6. What seemed to be the difficulty with them?

A. They didn't seem to have any power. Didn't seem to hold the train.

Q. 7. Did you consider them a safe brake?

A. I did not.

Q. 8. Did you or not feel safe on the train while those Springfield brakes were in use, or were you in fear?

A. I did not think they were safe, nor feel as though it was safe to ride on the train with those brakes.

Q. 9. Were you able to make good stops while those brakes were used?

A. Did not make very good stops; used to run by.

Q. 10. What brake was put on after they were taken off?

A. Hodge's brake, and I think it has been continued ever since.

Q. 11. Were you or not able to make goods stops with the Hodge brake, and did you feel safe on the train?

A. I considered them a good brake. Made very good stops, and considered them safe.

Cross-examined by M'r Whipple:

Cr. 1. Did you make good time with the Hodge brake?

A. We did.

Cr. 2. Did you make the same time with the Springfield brake between the two points, that is, Springfield and New Haven; and with this I mean to say did you arrive in Springfield and also New Haven on time?

1422 A. Used to have to run faster to make time. Were hindered a good deal by running by and backing up with the Springfield brake. Generally—sometimes were five or ten minutes late.

Cr. 3. Were you ever five or ten minutes late with the Hodge brake?

A. Might have been, sometimes. Generally made time with it.

Cr. 4. Did you generally make time with the Springfield brake?

A. We could not.

Cr. 5. Did you as a general rule arrive at New Haven on time with the Springfield brake?

A. Generally somewhat late.

Cr. 6. How much late?

A. From five to ten minutes.

Cr. 7. Was this always due to the brakes?

A. Not always. Sometimes had a hot box, or were hindered about getting baggage in; but as a general thing were hindered by the brakes.

Cr. 8. May not there have been other causes to delay a train besides hot boxes and taking in baggage? If so, state them.

A. There were various causes. Sometimes by waiting for trains; sometimes by heavy trains; might be by obstructions on the track.

Cr. 9. When all things were favorable did you you arrive at Springfield and New Haven on time as a general rule?

A. I think not.

Cr. 10. How many times in a week, should you judge, did you arrive in Springfield and New Haven behind time in consequence of the brakes?

A. Most every day.

Cr. 11. Are you quite sure that such is the fact?

A. I think I am.

Cr. 12. Do you feel perfectly safe on trains with the Hodge brake?

A. I do.

1423 Cr. 13. Is the Hodge brake a perfect immunity against accidents?

A. I think it is.

Cr. 14. Did you ever know of an accident to a train on the New Haven road the cars of which were equipped with the Hodge brake?

A. Accidents might have happened by running off the track or something of that sort; couldn't state every particular in regard to it.

Cr. 15. Do you consider trains equipped with the Westinghouse air brake, now in use on the New York and New Haven road, any more safe than when the same trains were stopped by man power and the hand brake?

A. I haven't been on the train since the air brakes have been put on.

Cr. 16. Do you think the officers of the New Haven, Hartford and Springfield road would run the express line of cars with the Springfield brake thereon if it was unsafe, as your testimony would seem to indicate?

A. I do not, if they found a better one.

Cr. 17. What better brake did they find?

A. Hodge's.

Cr. 18. What brake did they use on this line before they put the Springfield brake on?

A. Couldn't say.

Cr. 19. Have they ever used any other double brakes on the cars of the New Haven, Hartford and Springfield road besides the Hodge brake?

A. I couldn't state that.

Cr. 20. In running the express line of cars from Springfield to New Haven, did they run any other cars than the express line cars when the Springfield brake was on said cars?

A. I think not.

Cr. 21. Was it customary to run any New Haven cars on said express line from New Haven to Springfield, or any other cars than express line cars?

1424 A. They might sometimes.

Cr. 22. If they did so run such cars, for what purpose were they run?

A. To carry passengers.

Redirect by M'r Sayles:

Q. 12. Might they not have run some of the New Haven, Hartford and Springfield cars occasionally on the express trains from Springfield to New Haven when the Springfield brake was used?

A. They might.

Recross by M'r Whipple:

Cr. 23. For what purpose were these cars run if at all occasionally on said express line?

A. To have room, I suppose, for passengers.

Cr. 24. Do you know of their being put on for any other purpose than to convey passengers?

A. I do not know any other reason.

ERASTUS UPSON.

Deposition of L. F. Crane, taken at New Haven, Oct. 14, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. L. F. Crane; 47; New Haven; tallyman for steamboat company.

Q. 2. Have you ever been employed on railroads; if so, in what capacity, and when were you so employed?

A. I have been employed on railroads as brakeman, baggage master, and conductor on the New Haven, Hartford and Springfield Railroad, between 1857 and 1865.

1425 Q. 3. Were you a brakeman on said railroad in 1857; if so, on what trains?

A. On the day express in 1857.

Q. 4. Do you remember a brake being used on the New York and Boston express-train about that time called the Springfield brake?

A. I do.

Q. 5. Did you use that brake?

A. I did.

Q. 6. About how long was that brake used on those express-trains?

A. I should say it was a year or more.

Q. 7. From what point to what point did you run on those trains at that time?

A. I ran from New Haven to Springfield, and back.

Q. 8. How did those Springfield brakes work?

A. They didn't work to suit me.

Q. 9. What seemed to be the trouble with them?

A. The brake wouldn't hold the car.

Q. 10. Were you able with those Springfield brakes to stop the train properly at stations?

A. Not at all times.

Q. 11. Did you consider them a safe brake for stopping trains?

A. I did not if all the brakes were that same kind on the same train.

Q. 12. How did those Springfield brakes operate in switching cars in making up trains; could you hold the cars with them?

A. Could not.

Q. 13. What kind of brakes were used on the cars belonging to the New Haven, Hartford and Springfield Railroad at the time these Springfield brakes were being used on the line cars, and before and since?

A. The brake used at that time was a lever across under the centre of the car.

1426 Q. 14. Were any of those cars ever attached to the express-trains at Springfield and run through to New Haven?

A. They were.

Q. 15. Did you often brake upon them?

A. I did.

Q. 16. How did they answer the purpose of stopping the train at stations, compared with the Springfield brakes?

A. The brakes on cars that belonged to the Hartford and Springfield road worked well.

Q. 17. Did you brake on the local trains between New Haven and Springfield while those centre lever brakes were on the cars; and, if so, how did they work?

A. I did, about one year and one half—might have been more than that. The brakes on the local cars worked well.

Q. 18. Did you consider the Springfield brake a safe brake, and did you feel safe on the trains while they were used?

A. I did not consider it a safe brake. I did not.

Cross-examination by M'r Whipple:

Cr. 1. Did you ever brake on a train on which the Hodge brake was used, the same as are now in use on the cars of the Hartford and Springfield road?

A. I have.

Cr. 2. Of the three brakes, Springfield brake, centre lever brake, and Hodge brake, which do you prefer?

A. I should prefer the Hodge brake.

Cr. 3. What reason can you give for such preference?

A. The reason is this. The brake that I was using at that time I took to be the Hodge brake, although I didn't examine nor know what the name of it was, although I knew it was a good brake.

1427 Cr. 4. May not the Hodge brake, the centre lever brake, and the Springfield brake, be all good brakes if properly applied, mechanically, and adjusted, and the wear of the shoes taken up?

A. The Hodge brake, and the Hartford and Springfield brake are a good brake. But the Springfield brake I don't consider good.

Cr. 5. Are you sufficiently acquainted with the construction and application of brakes to cars to say that the Springfield brake cannot be so constructed and adjusted as to hold a car as well as the Hartford and Springfield brake?

A. I do.

Cr. 6. You will please describe the construction and operation of the Springfield brake, and state wherein it is not capable of holding the car as well as the Hartford and Springfield brake?

A. The Hartford and Springfield brake would hold the car, and the Springfield would not; I could depend on that when I couldn't on the other.

Cr. 7. What was there defective in the construction of the Springfield brake that would not hold as well as the Hartford and Springfield brake?

A. The reason is this. When I applied the brake I knew as soon as I wanted to get a car to a certain point that I was on that brake (the Springfield) because it wouldn't hold. It wouldn't hold the car.

Cr. 8. May not the Springfield brake be so constructed and applied to a car as to hold it as a car ought to be held by the brakes?

A. I never saw it.

Cr. 9. Did the train with said Springfield brake on usually make time between New Haven and Springfield and return?

A. I never had anything to do in regard to the time at all.

Cr. 10. Did not you as a brakeman know whether a train made its time or not?

A. Sometimes the train was late from causes I didn't know—south and north.

1428 Cr. 11. How frequently was it late in which you could properly attribute it to the brakes?

A. At one time at Springfield we had to switch out a car and put it into the car-house; at this time, in switching this car—in running into the car house—supposing I could hold it at the same distance I usually did other cars, I applied the brake as I would any other car with a proper brake, and I run against the side of the building and the bunter went through the brick wall. The switching of this car made it late.

Cr. 12. Is that the only instance in which a late arrival of the train can be attributable to the brake?

A. None that I remember of. I don't remember of any time that the train was late in consequence of the brakes.

Redirect:

Q. 19. Did you not add to the answer to the last cross-question that you would sometimes run by stations and have to back up, and then run fast to make up time?

A. I did.

L. F. CANE.

Deposition of Edward Reynolds, taken at New Haven, October 14, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. Edward Reynolds; age, 47; residence, Springfield, Mass.; occupation, baggage-master New York, New Haven and Hartford Railroad.

Q. 2. Were you ever brakeman on the New York and Boston express trains?

A. I was.

Q. 3. Were you brakeman on said trains in 1857 or 1858?

A. Yes.

1429 Q. 4. Do you remember of a brake called the Springfield brake being used on said New York and Boston line of cars about 1857 or 1858?

A. Yes.

Q. 5. How did they work? Answer fully.

A. They didn't work, as you may say. Furthermore, they were not a safe brake to use, as we found out since. That's pretty plain too.

Q. 6. Were you, or not, able to stop trains at stations as a general rule, or did you run by often?

A. Couldn't depend upon them at all.

Q. 7. Did you, or not, feel safe on the train while those brakes were in use?

A. I couldn't say that I did.

Q. 8. In what capacity were you acting on the train when those Springfield brakes were used, and from what points did you run?

A. From New Haven to Springfield, as brakeman.

Cross-examination by S. M. Whipple:

Cr. 1. In answer to fifth direct question you say that the Springfield brakes were not a safe brake to use, "as we found out since." What do you mean by the words "as we found out since"?

A. As far as this, they were not a brake you could depend upon. The cars were liable to come together any moment.

Cr. 2. Question repeated. What do you mean by the words "as we found out since"?

A. That we had better brakes since the time they had them on.

Cr. 3. What brakes have you had since you had those on?

A. I can't say what the name is; for I pay no attention to the names of the brakes.

Cr. 4. Is that the way you found out that the Springfield brake was not a good brake, by the company's putting on afterwards a better brake?

1430 A. It was.

Cr. 5. How long did the company use this Springfield brake, and in what years did they use it?

A. I should think about two years or so, as near as I can recollect. About 1857.

Cr. 6. Is this New York express line, on which these brakes were used, a fast train?

A. It was the fastest train on the road.

Cr. 7. Did the engineer make his time with these brakes from one end of the road to the other?

A. Not at all times.

Cr. 8. How often did he fail?

A. Well, I can't say; but very often.

Cr. 9. Was his failure to make time always attributable to the brakes on the train?

A. That was the fault claimed by the engineer; most generally he complained that it was the bad braking.

EDWARD REYNOLDS.

Deposition of John D. Sherwood, taken at New Haven, Oct. 14, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. Name, John D. Sherwood; 38 years; New Haven; hotel keeper.

Q. 2. Were you ever brakeman on a railroad; if so, what road?

A. On the Harlem and New York and New Haven.

Q. 3. What trains were you brakeman on on the New York and New Haven road?

A. On nearly all the trains.

Q. 4. Were you or not brakeman on the New York and Boston express trains about 1858?

A. About that time I was.

1431 Q. 5. Do you remember, while you were braking on that train, of a brake being used on cars of that train, called the Springfield brake?

A. I do from reputation, and we used to curse it.

Q. 6. How did that Springfield brake work? Please answer fully.

A. As far as I had any connection with them, they were a very poor brake. It was very hard work to stop a train with them; required a good deal of manual labor. We had not the purchase, and they were not as elastic as the brakes used on the New York and New Haven road; would not hold a train near as well as the brakes on that road; did not consider those cars that those brakes were attached to as safe cars to get between to couple—that is, in all cases—that is, at all times. Sometimes the brakes were better than at other times.

Q. 7. Could you not rely upon them to stop the trains at stations, as a general thing?

A. As a general thing we stopped the trains at stations where we were ordered to stop. At times we would run by. We will, with most any brake, do that. Only difference was, if we had a poor brake, we would brake quicker than with a good brake. I mean by that, we would commence to brake quicker.

Q. 8. Was this Springfield brake considered a safe brake by the men on the train that you were on?

A. I can't answer for the men. To the best of my knowledge, young as I was in the business, I didn't know the difference—that is, as far as safety.

Q. 9. About how much quicker could you stop a train with the brakes that were on the New York and New Haven cars, than with the Springfield brakes on the line cars?

A. I am undecided about that. Shouldn't wish to answer anything I don't know about.

Cross-examination by M'r Whipple:

1432 Cr. 1. Between what points did you run as brakeman on the New York and Boston express line when the cars of said line had the Springfield brake on?

A. From New to New Haven, and return, each day; what is called the day express.

Cr. 2. Is that train the fastest train that runs over the New York and New Haven road?

A. I think at that time the night and day expresses were considered the fastest trains.

Cr. 3. What was the time between New York and New Haven?

A. I could not tell; should think about three hours.

Cr. 4. Whatever the time was between the two points named in your previous answer, did you make it?—that is to say, did you arrive at New Haven on time when said Springfield brakes were in use on the cars of said express line?

A. As a general thing, we did.

Cr. 5. Did you also make your time from New Haven to New York?

A. As a general thing, when the eastern trains were on time.

Cr. 6. Did you run as brakeman on said express line before and after the Springfield brakes were used on said line?

A. Never but one kind of brake while I ran on said train—to my knowledge.

Cr. 7. Do you know that that kind of brake was the Springfield brake?

A. Only as I heard it called so. Not to my personal knowledge.

JOHN D. SHERWOOD.

1433 *Deposition of John T. Dade, taken at New Haven, Oct.* 14, 1872.

Direct examination by M'r Sayles in person:

Q. 1. What is your name, age, residence, and occupation?

A. John T. Dade; 43; New Haven; U. S. mail carrier.

Q. 2. Have you ever been engaged on a railroad; if so, when and in what capacity, and on what road?

A. I have; on New York and New Haven Road; about sixteen years; in various capacities.

Q. 3. Were you brakeman on the New York and Boston line cars about fifteen years ago?

A. I wasn't a regular brakeman on them—I was running more or less at times when they required an extra man.

Q. 4. Do you remember a brake being used on those line cars about that time called the Springfield brake?

A. I do.

Q. 5. Did you use that Springfield brake when it was on said line cars; if so, how did it work?

A. I did. It worked very unsatisfactory. Didn't consider it a safe brake. Almost impossible sometimes to hold a car by itself while the car was in motion. As a general thing—when making up trains—when cars with those brakes on came along we would generally sing out to one another, "Here comes an old Springfield brake. Look out for it."

Q. 6. Was it or not difficult to hold a single car by itself and keep it from running against other cars harder than it should—when making up trains?

A. Yes, it was; you could place no dependence on the brake.

1434 Q. 7. Did you or not often run by stations when using these Springfield brakes?

A. Yes, we did.

Cross-examined by M'r Whipple:

Cr. 1. When did you first hear this brake called the "Springfield brake"?

A. About the time it first came on the road; fourteen or fifteen years ago. I couldn't state any particular time.

Cr. 2. May it not be possible that you never heard the term "Springfield brake" until M'r Sayles told you the name it was called by?

A. No.

Cr. 3. Did the trains arrive as a general rule at stations on time when this brake was on?

A. That I couldn't say. We might lost time in running by a station and made it up. In those days we used to run at pretty big speed to make up the time.

Cr. 4. Does that train, as a general rule, now arrive at stations on time?

A. Well, this summer and this fall they haven't—run very heavy trains—double the amount of cars on trains that they used to run in those days.

Cr. 5. Did you run on that train after the Springfield brake was taken off; if so, did it arrive at stations as a general rule on time?

A. I did. As a general rule it did. We stopped the trains easier—could place more dependence on the brakes. Could stop at stations and at water-tanks with more dependence on the brake. As a general thing—with good brakes—could stop almost within three feet.

Cr. 6. Could you stop at stations and water-tanks with the Springfield brake?

A. We might one time out of ten—but chances are we would go a train's length by them.

1435 Cr. 7. Then as a general rule you wish to be understood, do you, that you brakemen were obliged to let the train run the length of it by a station, while with another brake you could stop within three feet of where you wished to?

A. I do.

Cr. 8. How many lengths of train does it require ordinarily to stop a train, at ordinary speed on level grade, at about twenty-five miles an hour?

A. About two hundred and fifty feet.

Cr. 9. How many feet do think it required to stop a train with the Springfield brake?

A. I think in cases I see them work sometimes, it would be almost impossible to stop them anyway.

Cr. 10. A train would stop, I presume, if it hadn't any brakes, sometimes.

A. I suppose if it struck an up grade, and the engineer might stop it by reversing his engine.

Cr. 11. You will please now state how many feet in your judgment it would require to stop a train, say of six cars, three brakemen; the train running at a speed of twenty-five miles an hour, level grade and no reversing of the engine, with the Springfield brake on the cars?

A. I should think, in the best of my judgment, from five hundred to seven hundred feet.

Cr. 12. Do you think, as a general rule, the train was stopped with the Springfield brake within from seven hundred to one thousand feet?

A. I do not.

Cr. 13. What number of feet would you like to add to seven hundred feet?

A. The possibility was that they might be stopped, and then again there was no dependence to be placed as to what you could stop them at.

Cr. 14 Stopped at what?

A. They might run 1,200 feet.

Cr. 15. How often did they exceed 1,200 feet in your judgment?

1436 A. Couldn't say.

Cr. 16. Did the stopping of the train sometimes fall short of 1,200 feet as well as run above?

A. I never knew them to stop short of station. You couldn't stop the train with those brakes within the same distance of those brakes they are using now; not by one half. I mean the Hodge hand-brake.

Cr. 17. You said those brakes they are using would stop a train in 200 to 300 feet; how many more feet would you wish to add to that?

A. I would say in 3 train lengths, now, if the brakes were in good order; couldn't say about the feet.

Cr. 18. How many train lengths do you think it would require to stop the train with Springfield brakes on level grade; speed 25 miles an hour?

A. I should think to the best of my judgment it would take double the length it would to stop with the other ones.

Cr. 19. You say in making up trains you used to call out to the brakemen: "Look out for the Springfield brake;" what other cars and other brakes were used to make up this train called the express line?

A. We used our own local cars; the New York and New Haven road. Generally left those cars at Stamford; sometimes brought them to New Haven.

Cr. 20. For what purpose were these local cars put into this express line?

A. At times when they had a rush of travel to Stamford to carry passengers; sometimes to use on morning trains.

Redirect by M'r Sayles:

Q. 8. In your cross-examination you have spoken of stopping trains at a certain number of feet. Had you any idea of the number of 1437 feet it required to stop a train at the time you made those answers; and you afterwards stated number of lengths of trains. How do you wish to be understood?

A. I had no definite idea of the number of feet it required. Would be understood that we calculate to stop a train within about three lengths of an ordinary train.

JOHN P. DADE.

1438 Depositions of George Churchill and W'm Geddes, both of Greenbush, New York, taken before me, Amasa J. Parker, j'r, a United States commissioner in and for the northern district of New York, at the city of Albany, in the State of New York, on the 16th day of October, A. D. 1872, to be used on a final accounting before the master. Present, complainant in person, and S. M. Whipple for defendant.

Direct examination by M'r Sayles in person:

Q. 1. What is your name, age, residence, and occupation?

A. Name is George Churchill; age, 22 years; residence, Greenbush, New York; and occupation a fireman on the Boston and Albany Railroad.

Q. 2. How long have you been a fireman on said railroad?

A. I have been there about four years.

Q. 3. What train were you fireman on previous to July last?

A. J. B. Adams' train. William Geddes was engineer.

Q. 4. How long were you fireman on that train?

A. About six months.

Q. 5. During the time you were fireman on Adams' train did you notice any difference in the stopping of the trains at the stations; if so, what was the difference?

A. I noticed every other day that the trains did not stop so well at the stations as they did every alternate day.

Q. 6. Please state, if you know, the cause of their not stopping one day as they did another.

A. I asked M'r Taylor, the brakeman on the train, what the cause
was. He said he had the double chain-brakes, or the Springfield
1439 brakes, every other day, and he could not hold the train so well
as when he had the Hodge brake.

(Answer objected to as hearsay.)

Q. 7. How was the train stopped the days when they had those Springfield brakes on the train?

A. They were dragged into the stations. What I mean is, they applied the brakes so far back from the station. It took so long to stop that we could not make up the time between stations.

Q. 8. While those Springfield brakes were on the train that you were fireman on, what, if anything, did the engineer do to assist in stopping the train at the stations?

A. He would reverse his engine.

Q. 9. About how often did the engineer reverse his engine to stop the train?

A. About half the time. At about every other station.

Q. 10. Between what points did you run on that train?

A. Between Pittsfield and Albany; every other day.

Q. 11. While running the train, alternate days, which had on the Hodge brake, did you have any trouble in stopping at stations?

A. We did not.

Q. 12. Did M'r Geddes have to assist in stopping the train, by reversing his engine, when the Hodge brake was used?

A. I think not.

Cross-examined by S. M. Whipple:

Cr. 1. Are you still in the employ of the Boston and Albany Railroad Company as fireman?

A. I am.

Cr. 2. On what train do you now run, and who is engineer?

1440 A. I fire for W'm Geddes. I have no regular train now. My
engine has been in the shop for repairs.

Cr. 3. How are you employed at the present time?

A. I am employed as a fireman on a freight train run by W'm Geddes.

Cr. 4. At what time did you leave firing for W'm Geddes on M'r Adams' train?

A. The 4th of July last.

GEO. CHURCHILL.

Deposition of William Geddes, above named.

Direct examination by M'r Sayles in person:

Q. 1. What is your name, age, residence, and occupation?

A. W'm Geddes; about 35 years; Greenbush; and a locomotive-engineer.

Q. 2. How long have you been a locomotive-engineer on the Boston and Albany Railroad?

A. Ten years. This railroad was formerly known as the "Western Railroad Corporation."

Q. 3. What train did you run previous to 4th of July last, and how long did you run it?

A. John B. Adams' train I ran previous to 4th of July last for about six months.

Q. 4. What kind of brakes were used on M'r Adams' train?

A. One day we ran the Hodge brakes and the next day we used the Springfield brakes, as I was informed.

Q. 5. About when did the Springfield brakes appear on the train, as you were informed?

1441 A. I cannot say as to that. I found, about a month or so after I had been on this train, that they claimed there was a difference every other day about the brakes. All I know is through M'r Taylor, the brakeman. At some of the stations they missed holding the train as they ought to hold.

Q. 6. Did they, or did they not, often run by the stations when those Springfield brakes were on the train?

A. There were times when they could not hold the trains at the stations as they ought, and I could not say which the brakes were—only from what M'r Taylor said. M'r Taylor said it was the Springfield brake that would not hold the train at these times.

Q. 7. Did or not the brakemen apply the Springfield brakes, as they call them, so far back from the stations and drag the train into the stations so far that you found fault with the brakeman for so doing?

A. They claimed that they commenced to hold the train back far enough, and I asked them why they did so, and the brakemen told me they could not depend upon the brake unless they commenced so far back. They also said they were short-handed sometimes. They had but two brakemen on that train.

Q. 8. What, if anything, did you do to assist in stopping the train at stations, every other day, when they said they had the Springfield brake?

A. I applied the tender brake at times, and then again I reversed the engine to assist them, but I cannot say which day it was I assisted them. I assisted them when I saw they were running past the stations.

Q. 9. Was it the days they said they had the poor brakes that you assisted them in the manner aforesaid?

A. I cannot say that. I may not have spoken to them on all those days.

Q. 10. Who was your fireman while you ran Adams' train?

A. George Churchill—the man who has just testified in this case.

Q. 11. Did you hear his testimony this evening?

1442 A. Yes, a good portion of it. I did not pay particular attention to all of it.

Q. 12. Did you or not hear the brakemen on Adams' train often complain of the Springfield brakes working very badly?

A. I have often heard them speak of bad brakes. They called them the Springfield brakes, and said they could not hold with them. Sometimes I thought the brake might be out of order, and sometimes I thought the brakemen might be to blame.

Q. 13. Did you ever hear them complain of the Hodge brakes not working well before the Springfield brakes were used on that train, or after?

A. Not that I know of.

Q. 14. Between what points did you run on Adams' train?

A. Between Pittsfield and Albany.

Q. 15. Did you or not tell M'r Taylor, the brakeman, not to apply the brakes so far back from the stations, for it took too long a time to stop, and that you would prefer to reverse your engine to assist him in stopping?

A. Yes, sir; I did.

Q. 16. Was this said to M'r Taylor, the brakeman, at a time when he had commenced to brake a long ways back from the station?

A. Yes, and when they had dragged me into the station for a long way.

Cross-examined by S. M. Whipple:

Cr. 1. How long after the Springfield brake was applied to M'r Adams' train did you find by hauling the train that there had been a change in the brakes?

A. I cannot say when I found out exactly. It might have been a month or longer before I heard any fault found.

Cr. 2. So far as holding M'r Adams' train each and every day, do you wish to be understood that you discovered no difference for a month or more?

1443 A. I did not notice any difference for a month or more.

Cr. 3. Did you ever discover any difference in holding the trains, except when you were told by the brakemen that there was a difference?

A. No, sir.

Cr. 4. Are you still in the employ of the Boston and Albany Railroad Company?

A. Yes, sir.

Cr. 5. Did you ever run past stations with the Hodge brake?

A. I cannot say.

Cr. 6. Did you ever run past stations with the Springfield brakes?

A. So far as I knew I did not know one brake from another—only as the brakemen told me.

Cr. 7. So far as you know were you as likely to run by the stations one day as another?

A. Yes, sir; as far as I knew what brakes they were.

Cr. 8. Was there so much difference between the Hodge brake and the Springfield brake that you could tell by stopping the train which brake was on?

A. No, sir; for the reason it might be the fault of the brakeman as well as the brake.

Cr. 9. How many brakemen were on this train?

A. Only two brakemen; the regular train was five cars. Sometimes we ran six or seven cars.

Redirect:

Q. 17. Did you or did you not know that there was a difference in the brakes when the trains did not stop at the stations without the brakemen telling you so?

A. No, sir; for the reason that the brakemen might not have done their duty.

1444 Q. 18. Did you or not ask the brakemen why they did not make as good stops one day as they did another—that you had noticed every other day that they made poorer stops?

A. Yes; I did ask them that.

Q. 19. Was that true that you had noticed that they did not stop as well one day as they did the next—that is, that they made poorer stops every other day?

A. Yes; I did notice a difference some days. I cannot say every other day that they made poorer stops.

Recross-examination:

Cr. 10. May not the brakemen have made poorer stops on the days when the Hodge brakes were used?

A. Yes, as far as I know. I did not know when they had the Hodge brake—only what I was told.

Cr. 11. How many times in a week did you reverse to help the brakemen?

A. I cannot say as to that.

Cr. 12. Would you be as likely to reverse one day as another?

A. Yes, for all I know. I did not know which days I had on the Hodge brake.

Cr. 13. Did you know which days the Springfield brake was used?

A. No, sir; I did not.

Redirect-examination:

Q. 20. In your last answer you say you did not know which days the Springfield brake was used; do you mean that you did not know one brake from another of your own knowledge?

A. No, sir; I did not know one brake from another. That is what I meant.

1445 Recross-examination:

Cr. 14. Do you know anything about the Hodge or Springfield brake used on John B. Adams' train, except what has been told you?

A. No, sir; I do not.

(Objection made to use of this evidence on accounting, by defendants' counsel, as it did not come to knowledge of witness, but is mere hearsay evidence.)

W. GEDDES.

Taken before me, after being duly sworn, this 16th day of October, 1872.

AMASA J. PARKER, J'R,
U. S. Commissioner in and for N. D. of N. Y.

1446 TESTIMONY ON BEHALF OF THE COMPLAINANT, TAKEN AT THE CITY OF NEW YORK.

Deposition of G. A. Fuller, taken at New York, Oct. 8, 1872.

Direct examination by M'r Sayles in person:

Q. 1. What is your name, age, residence, and occupation?

A. G. A. Fuller; age, 45; residence, New York City; occupation, expressman.

Q. 2. Were you employed on the Boston and New York line cars some fifteen or sixteen years ago?

A. Yes, sir.

Q. 3. In what capacity?

A. Through baggage-master from New York to Boston.

Q. 4. Do you remember about that time a certain brake being put on the cars of that line by the Western Railroad Company, called the Springfield brake?

A. Yes, sir.

Q. 5. How did that brake work?

A. Not so well as the brakes that they had had on previously and afterwards.

1447 Q. 6. About how long was this Springfield brake used?

A. About a year.

Q. 7. Did you feel safe on the train while those Springfield brakes were used?

A. I didn't think they were as safe as the old brake. I didn't think they could stop a train as quick. We didn't rely on them as well as we did on the cars that had the old-fashioned brake on that was used before this Springfield brake was put on.

Q. 8. Were the trains stopped as regularly at stations while those brakes were used as they were before and after?

A. Well, there wasn't so much difference in stopping a train at a station, because the engineers would shut off in time to give all the brakemen and baggage-masters time to stop at stations. In them days we didn't have any steam brakes as they have now.

Q. 9. Were those brakes complained of very much by the men running on the trains while they were used?

A. I didn't hear much complaint, because I wasn't with the men on the Boston and Albany Railroad.

Q. 10. I mean on the road that you run clear through on.

A. They didn't like them as well as the old brakes. It is so long ago I have forgotten a great deal about it.

Cr. 1. On what road are you running as an expressman now?

A. Expressman on the Erie road, between here and Paterson.

Redirect:

Q. 11. You spoke of the engineer shutting off so as to give 1448 baggage-masters and brakemen a chance to stop at stations. Did you mean that they shut off further back than they did when they used the other brake?

A. I think they did.

G. A. FULLER.

Sworn to before me this 8th day of October, 1872.

T. B. BEECHER,
Notary Public, N. Y. County.

Deposition of Samuel P. Rand, taken at New York, Oct. 9, 1872.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Samuel P. Rand. I am locomotive-engineer; reside in New Haven, Conn., and am 49 years of age.

Q. 2. Upon what railroad are you engaged?

A. The New York and New Haven it has been always called. It is now called the New York, New Haven and Hartford Railroad.

Q. 3. How long have you been locomotive-engineer upon that railroad?

A. Since the 27th of November, 1851.

Q. What train at the present time do you run on?

A. The way and express passenger; it is the way one way, down from New Haven, and express up.

Q. 5. Is it the Shore Line express going up?

A. Yes, sir.

Q. 6. What kind of trains have you been running on as locomotive-engineer most of the time since you have been on said road?

1449 A. For the first fourteen months I was on the freight train; since that I have been on the passenger train.

Q. 7. Since you have been engineer on that road, have you run on the New York and Boston night express line?

A. Yes, sir; for twelve or thirteen years.

Q. 8. At any time while you ran as locomotive engineer on that night express line, do you recollect a peculiar kind of brake put on the cars of that line by what was then called the Western Railroad Company of Massachusetts?

A. I do, perfectly well. I couldn't designate the time when it was put on, but I was running the train both before and after, and all the time it was on.

Q. 9. While you ran that train with those brakes on it, how well did said brakes answer:

A. Well, we couldn't depend upon the brakes at all. We had to shut off steam a long ways further back than usual, in order to fetch up at stations or drawbridges. There wasn't much dependence to be placed on the brake. They only run to Forty-second or Thirty-second street with steam, and then they had to run the cars to the depot with horses; and oftentimes they had to cut the horses off—the brake wouldn't hold a single car. They would cut the horses off for fear the car would run over them in going into the yard at the depot.

Q. 10. While these brakes were used on that train, how did you feel as to the safety of the train?

A. Well, we didn't of course feel as safe with what we knew was a poor brake as we did with a good brake. The brake which we were using at that time gave a great deal of dissatisfaction.

Q. 11. Do you recollect an accident happening to the night express train while these brakes were on it?

A. I do, perfectly well.

1450 Q. 12. What was the accident? Please state it fully.

A. I was running the train at that time—coming down from New Haven. We got signals of danger about two miles, I should judge above Stamford. First there was torpedoes—two of them—put on the rail as a signal of danger, and then we got around the curve and saw a red light; I should judge it was fully half a mile from the hind end of the train that we ran into, that I saw the red light. It might have been further. Well, we run into the hind end of the train, as I said. I should judge we were going nearly as fast as we were when we saw the red light. I gave the signals to brake. The caboose car that was on the hind end of the freight train was an old passenger-car. It was one that was broken in two at the Norwalk accident, and they refitted it and put it on for a caboose. Well, the hind trucks of that caboose car was up on the dome part of my boiler—next to the house, and the forward pair of trucks were up on the smoke arch of the engine; the smoke-stack was off in the lot.

Q. 13. To what do you ascribe the failure to stop the train on this occasion in time to prevent the accident?

A. Poor brakes.

Q. 14. What brakes do you refer to when you say "poor brakes"?

A. The brakes put on by the Western Railway Company.

Cross-examination by M'r Whipple:

Cr. 1. Did you reverse your engine at the time?

A. I did, sir.

Direct examination resumed:

1451 Q. 15. In your judgment was the distance from the point where you saw the red light to the place where the accident occurred sufficient or not to have stopped the train, if you had had the kind of brakes on the cars which were on before and after these Western Railroad Company brakes were put on?

A. It is my candid opinion we would have been stopped in half the distance with proper brakes, or with the brakes we used before and since. I think that a quarter of a mile is ample distance for braking, with the train we was running at the time.

Q. 16. Do you know John Charts, now baggage-master on the New Haven Railroad?

A. I do.

Q. 17. Was he a brakeman on the train at the time of this accident at Stamford?

A. Yes, sir; hind brakeman on the train.

Q. 18. While this brake put on by the Western Railroad Company was on that Boston and New York express line which you ran, were any cars with another kind of brake on them run in said train?

A. On leaving New Haven we would take on one of our local cars for the purpose of holding the train.

Q. 19. What kind of brake did those local cars have?

A. The same as we used before and after.

Q. 20. Do you remember the name of that brake?

A. It was called the "Hodge brake."

Q. 21. When taking on a car at the rear of the train at New Haven, as stated, and none of your local cars were convenient for the purpose, what other car, if any, did you frequently put on?

A. We used to take one car that was brought through from Springfield, belonging to the Hartford and New Haven Railroad Company; we would take one of those cars along and let it remain on, instead of cutting off and taking on one of our local cars.

1452 Q. 22. And on such occasions did such Hartford and New Haven car run through to New York on the rear of the train?

A. It did.

SAMUEL P. RAND.

Sworn to before me this 9th day of October, 1872.

T. B. BEECHER,
Notary Public, N. Y. County.

Deposition of Henry Blessing, taken at New York, Oct. 9, 1872.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Henry Blessing; I am 35 years of age; reside at 127th street, between 9th and 10th avenues, New York, and am engineer in the New York fire department.

Q. 2. Were you ever in the employ of the New York and New Haven Railroad Company; if so, when, and in what capacity?

A. Yes, sir; I commenced there in 1856 as fireman.

Q. 3. Fireman on what?

A. Fireman on the Boston express.

Q. 4. About how long did you work for them as fireman?

A. Well, I worked six or seven years. I didn't commence exactly on the start on the express; I was eight or nine days on another train before I commenced on the express train.

Q. 5. Did you remain on the express train all the rest of the time as fireman?

A. Yes, sir; all the time till I left the road.

1453 Q. 6. You say you were on the Boston express train. Was it the day or night express?

A. On the day-express and on the night-express. On the day-express four months, as near as I can recollect.

Q. 7. And the rest of the time on the night-express?

A. Yes, sir; on the Boston night-express.

Q. 8. While you were fireman on the Boston night-express, who was the engineer that you ran with?

A. Samuel P. Rand.

Q. 9. Do you remember what kind of brakes were on the cars of this night express train on which you ran?

A. Yes, sir; there was a brake they called the "Springfield brake"; and there was another brake there I think they called the "Hodge brake," if I am not mistaken. I won't be positive about that.

Q. 10. Did you run on the train as fireman all the time these Springfield brakes were on?

A. Yes, sir; I believe I did. They were on in the winter of 1856 and in 1857. I was on till coming on 1862. I was all the time on that train.

Q. 11. While these Springfield brakes were used on that train, how well did they answer to hold the train?

A. Well, they didn't act very well; they didn't work well; the men were always finding fault with them. They couldn't make good stops. We often run by stations and water-tanks, and had to back up. The engineer had to reverse the engine and back back, and they always laid it to those Springfield brakes.

Q. 12. Why did the engineer reverse his engine?

A. Well, the brakes wouldn't hold the train. He said that was the cause of it. I know I often used to take hold of the brake on the tender to help brake the train up when I saw the train running by stations, the engine being reversed at the same time.

1454 Q. 13. Do you remember, while these Springfield brakes were used on that train, of any accident happening to the train while you were on it?

A. Yes, sir.

Q. 14. Please state what that accident was.

A. Well, we run into the tail-end of a train the other side of Stamford, coming from New Haven—a freight-train ahead of us. They were stopped there, and they came back with a torpedo and put it on the track, and had a red signal to stop; and the engineer he shut off and reversed his engine, and pulled open the sand-pipes—that is, to let the sand run down on the track, and I put the brake on the tender, and he blowed for the brakes. The consequence was, we didn't stop; we run into the freight-train, and there was a caboose-car on the tail-end of the train. We struck that first and smashed it all to pieces, and broke several other cars. The truck of the caboose-car was drove up on top of the boiler—on the front end of it.

Q. 15. Who was fireman on the engine that ran into this freight-train at this time?

A. I was fireman.

Q. 16. About how far back were you signaled to stop by the red light referred to by you?

A. I don't know exactly how far it was, but I should judge it was a half mile or over. I never measured it, but I should judge it was that distance. I see the distance next day.

Q. 17. What do you think was the cause of the express-train not being stopped in time to prevent this accident?

A. I think those brakes were the cause of it.

Q. 18. What brakes do you refer to by "those brakes"?

A. The Springfield brakes—what they called the Springfield brakes.

Q. 19. If you had had on the train the other brake, which you have called the "Hodge" brake, do you think the distance was suffi-
1455 cient to have enabled you to have stopped the express-train in season to have avoided the accident?

A. Yes, sir; I think it would.

Q. 20. After the Springfield brakes were taken off that train, what brakes were put on in their place?

A. I believe the same brakes that were there formerly.

Q. 21. Called the Hodge brake, do you mean?

A. Yes.

Q. 22. When this Hodge brake was used on the train, how well were you able to stop at stations?

A. Well, they always made very good stops; always made good stops.

Q. 23. Did, or not, the engineer have to reverse his engine to help the train stop at stations while the Hodge brake was used?

A. No, sir; not to my recollection.

Q. 24. While the Springfield brakes were used on this train were cars with other brakes on them running in the train?

A. Yes, sir; we used to take on a car at New Haven on account of those brakes—one of the local cars of the New York and New Haven Railroad—on the tail end of the train, on account of the brakes being bad, to stop the train.

Q. 25. What sort of brake was on these local cars?

A. Well, I don't know exactly the name of the brake that was on those cars, but they were a good brake and never any fault found with them. I don't know the maker's name, nor the man's name that put them on. They was considered a good brake, and considered safe.

Q. 26. Were they, or not, the regular brake that was used on the local cars of the New Haven Railroad?

A. I believe they were the regular brake that is used on the local trains.

1456 Cross-examined by Mr Whipple:

Cr. 1. Was there on this train, at the time of the accident referred to by you, one of the local cars of the New Haven Railroad?

A. Yes, sir; I believe there were, to the best of my knowledge—to the best of my memory.

Cr. 2. Was this brake applied at the time of the accident?

A. Well, that I couldn't say.

Cr. 3. Was there any of the brakes of that train applied at the time?

A. Well, that I couldn't say. I wasn't on the train; I was on the engine.

Cr. 4. Why was the Hodge brake taken off from that train and the

Springfield brake put on; and then afterwards that taken off and the Hodge brake put on in its place?

A. All I knew about that was, I heard there was some difficulty about the brakes.

Cr. 5. From what source did you understand this difficulty to come?

A. Well, that is a question I couldn't answer. I never made any inquiries about that.

HENRY BLESSING.

Sworn to before me this 9th day of October, 1872.

T. B. BEECHER,
Notary Public, N. Y. County.

(Counsel for complainant notifies defendants' attorney that as these last two questions of the cross-examination are upon new matter, he makes the witness his own and will be held bound by them.)

1457 *Deposition of Edward S. Renwick, recalled on the part of complainant, taken at New York, Oct. 25, 1872.*

Direct examination by M'r Cozzens:

Q. 1. Please state whether you have examined any drawings or diagrams representing the car-brake known as the Springfield brake; and, if yea, whether you understand the construction and operation of that brake?

A. I have examined the diagrams, and believe that I understand the construction and operation of the brake as represented in them.

Q. 2. Please state what disadvantage, if any, would, in your judgment, attend the use of a brake like the Springfield brake in practice?

A. In my opinion, such a brake would not be a reliable one for stopping trains under the ordinary circumstances which occur in practice, because the construction of it is such that in cases which are continually arising in practice the whole strain from one of the brake standards would be thrown upon the shoes of one truck, and in case the brakeman had applied the shoes of both the trucks while the car was running upon a straight portion of the track, a transference of the car from such a straight portion to a curve would have the effect of slacking the strain upon the shoes of one truck, and of greatly increasing the strain upon the shoes of the other truck, so as, in all probability, to cause the wheels of such truck to slide upon the track. In fact, I should regard the Springfield brakes as less reliable than single brakes for the purposes of stopping a train under the cases which ordinarily occur in practice, and that the incidental disadvantages of a defective brake system—such as the risk of collisions and the injury of the wheels by sliding—would be greater with the Springfield brake than they
1458 are with the ordinary single brakes which were in use before the present system of double brakes.

Q. 3. Will you please state what it is in the construction of the Springfield brake which causes these results you have referred to?

A. In the Springfield brake the connections between the brake levers of each truck and the windlass at one end of the car are at the same side of the central line of the car. Now, when the railroad car is running upon a curved portion of the track the two trucks are canted in reference to the central line of the car, and the canting of the two trucks is in opposite directions; hence the effect of this canting is to shorten the distance between the brake lever of one truck and its brake standard, and to lengthen in a corresponding degree the distance

between the brake lever of the other truck and the same brake standard. Hence, if the brakes were applied properly when a car was running upon a straight portion of the track, and after such application the car passed to a curved portion of the track, the canting of one of the trucks, by increasing the distance between its brake lever and the brake standard, would greatly increase the strain upon the brake system and brake-shoes of that truck, while the strain upon the brake system and brake-shoes of the other truck would be reduced in like proportion. On the other hand, if the brakes were applied while the car was running upon a curved portion of the track, the brake-shoes of that truck whose brake lever was canted furthest from the brake standard would be brought into operation and pressed against the wheels to the greatest required extent, before the brake-shoes of the other system could be brought to bear against their respective wheels; so that practically, in such cases, the brake-shoes of only one of the two trucks of the car would be available for the purpose of stopping the car.

1459 Q. 4. Would a brake operating in this way be in your judgment a practical brake for a double-acting brake?

A. In my opinion it would not, because in cases which continually occur in practice of the passage of cars from straight portions of the road to curved portions—while the brakes are applied—and of the application of the brakes while the cars are running upon curved portions of the track, the brake-shoes of only one truck would be borne forcibly against their wheels, and the presumption is that in a majority of cases they would be borne against their wheels with sufficient force to cause the wheels to slide while the wheels of the other truck continued to revolve. In addition to the difficulty arising from the variation in the distance due to the canting of the trucks, the presumption is that a greater strain would be applied by the brake standard itself to the brake system of one truck, during such canting, when the car passes from a straight to a curved portion of the track, than to the brake system of the other, from the fact that the brake standard is mounted upon a wooden framing which is the wooden framing of the car and which is more or less elastic; consequently when the variation in distance arising from the canting of the trucks relaxed the strain upon the brakes of one truck, the elasticity of the frame-work of the car would in all probability cause an increased amount of strain to be applied to the brake system of the other truck.

**Q. 5. Assume that in the diagram marked "Hervey Waters' Radius Diagram Sheet No. 1," the radius of one of the curves there represented is 500 feet, and that when a car having upon it the Springfield brake passes from a straight track on to a curve of 500 feet radius, the relation of the top of the truck-lever to the windlass at one end of the car is varied an inch and a half at one end, and that the relation
of the top of the lever of the other truck to the same windlass is
1460 varied, say an inch and a quarter in the opposite direction; please
state how serious in your judgment would be the effect of these variations upon the wheels of the trucks in reference to efficient braking of the car?**

A. The effect would be substantially the same as that produced by making the connection between the brake standard of the one truck 2¾ inches longer than the connection between the same brake standard and the other truck when the car was running upon a straight portion of the track. The result in my opinion would be so serious that if the brakes had been applied when the car was running upon a straight portion of the track, the passage of the car to a curve of the radius mentioned

would, in all probability, so increase the strain upon the brake-shoes of one truck that the wheels would be forced to slide upon the track, while it would slack the strain upon the brake-shoes of the other truck. On the other hand, if the brakes were applied while the car was running upon a curve of the radius mentioned, the brakesmen might readily apply sufficient force to prevent the revolution of the wheels of one truck, without materially affecting the revolution of the wheels of the other truck.

Q. 6. Will you now look at "Hervey Waters' Radius Diagram Sheet No. 2," and answer the same question, on the assumption that the curve shown on said diagram sheet is of a radius of 800 feet, and that a car with the Springfield brake upon it properly applied upon a straight track, and passing upon said curve, causes an aggregate variation in the relations of the tops of the brake-levers in each truck to the windlass from which the power is applied, of about an inch and a quarter?

A. The risk of sliding the wheels of one truck would in such case not be so great as in the preceding case with the radius of 500 feet; but still a much greater amount of pressure would be applied to the brake-
1461 shoes of one truck than to those of the other, and there would be considerable risk of causing the wheels of one truck to slide; and the brake-shoes of the wheels of the other truck would not be applied with nearly as great force as they would be if they had been operated by a separate brake standard, as in the single brake system, and would not be as effective in stopping the motion of the train.

Q. 7. If, then, the effect of this variation on an 800 feet curve was to cause the wheels of one truck to slide, and the brake shoes of the other truck to be materially slackened in their pressure, would, or not, such a brake in your judgment be a practical brake to use on railroads?

A. Whether it would or would not be a practically valuable brake would depend upon circumstances. If no other brake system was known, the Springfield brake would be a valuable system; but if the single brake system were known, I should regard the Springfield brake system as of less value practically than the single brake system, because there would not only be a greater risk of causing the wheels of one of the trucks to slide, but it would be relied upon to do more work than the single brake system—while in point of fact it would be less reliable and more likely to increase the expense of running trains than the single brake system.

Q. 8. You have, in your previous examination upon this accounting, stated certain defects which exist in the single brake system. Will you also state the reason why the Springfield brake would be less reliable than said single brake system—although the latter has the defects referred to?

A. It would be less reliable than the single brake because one of the defects of the single brake system could be obviated, to a certain extent, by increasing the number of brakesmen; but in the Springfield system an increase in the number of brakesmen would really increase the risk of sliding the wheels of one truck, because the effect of the cant-
1462 ing of the trucks upon a curve would be to throw the strain from both brake standards upon the brake shoes of one truck. Moreover, the increase in the number of brakesmen operating the Springfield brake would for the same reason not increase the number of shoes which were brought properly into action by the operation of those brakesmen. Whereas, in the single system the increase in the number of brakesmen would increase the number of brake shoes brought into practical operation.

Q. 9. Also please state why it is that the Springfield brake—although it is an attempt to operate upon both the trucks of a car—is an inferior brake system as compared with a single brake at each end of a car with a brakeman at each of such single brakes.

A. It is inferior for the reason that in the Springfield brake both trucks of the car are connected with both brake standards, and the change in the relationship of the brake levers of the two trucks to one standard arising from the canting of the trucks when the car is running upon curved portions of the track is attended with a corresponding and equal change in the relationship of the brake levers of the two trucks to the other brake standard, but in the opposite direction—so that the connections of the brake levers of one truck with both brake standards would be shortened, while the connections of the brake levers of the other truck with both brake standards would be correspondingly lengthened. Hence, if under such circumstances with the Springfield brake a brakesman was to operate at each brake standard of a car, the force of both would be applied mainly, if not wholly, to the brake system of one of the trucks—instead of being applied separately to the brake systems of the two trucks as would be the case with two brakesmen operating upon a car having a separate brake for each truck.

Q. 10. You have fully stated the effect produced upon the
1463 Springfield brake by the canting of the trucks of the car when
the latter passes from a straight track on to a curve. Now, please state what effect is produced upon the brakes of the trucks of a car running under the same circumstances having a single brake at each end of it?

A. In the single brake system there would be more or less variation in the pressure of the brake shoes that were in operation, arising from the passage of a car from a straight track to a curved one—such variation arising from the canting of the truck and the consequent change in the position of the brake lever relatively to its brake standard. But inasmuch as the brake system of only one truck of each car is connected with one brake standard, such variation in the pressure of the brake shoes of one truck could not affect the brake shoes or the wheels of the other truck.

Q. 11. If then the variation in the pressure of the brake shoes of one truck with the single brake would not affect the shoes of the other truck, and if the defect existing in the single brake of not applying to more than one truck at a time could, as you have above stated, be obviated to a certain extent by increasing the number of brakemen—will you please state why it is in your judgment that notwithstanding these facts the single brake system is not as efficient for the purpose of braking a car as the double brake system embodied in the Tanner patent?

A. Because, setting aside the increased cost due to the necessity of employing double the number of brakesmen in order to bring the same number of shoes into operation with the single brake system as could be brought into operation with the Tanner system, the risk of sliding the wheels with the single brake system is greatly more than it is with the Tanner system for the reasons given by me in my previous examination on this accounting; and as a consequence, although it is possible
that a train with the single brake system could be stopped as
1464 efficiently as with the double brake system, yet it is not at all
likely that it would be in practice; and the presumption is that in a great majority of cases the train would not be as effectively stopped with the single brake system with double the number of brakesmen as

with brakes upon the Tanner system. An increase of the number of brakesmen also reduces the chances of simultaneousness in applying the brakes—so that although it is possible that the brakes of a train having the single brake system could be applied as simultaneously as those of a train having the Tanner system of brakes, it is not at all likely they would be in practice in a majority of cases.

Q. 12. Please state whether or not there is anything in the combination and arrangement of the levers in the Tanner brake which practically obviates the defective results which you have spoken of as existing in the single brake and in the Springfield brake when a car with its brakes properly applied on a straight track passes on to a curve; if so, what is it?

A. There is—namely, an arrangement of the brake levers of the trucks substantially in a line passing through the king bolts of the trucks and the long connections between those brake levers and the central lever with which the brake standards are connected. In consequence of this arrangement of the brake levers and connections, the canting of the trucks when the car is passing from a straight portion of a track to a curve, or when the car is on a curve, produces an insignificant effect in the relationship of the brake levers to the central lever through which the force is applied from the brake standards.

(Cross-examination waived.)

E. S. RENWICK.

1465 *Deposition of Cornelius Van Demark, taken at New York, Oct. 25, 1872.*

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. Cornelius Van Demark; I am about 45 years of age; I live in Jersey City, and am foreman of car repairs on the Pennsylvania Railroad at Jersey City—foreman of car inspecting for the Pennsylvania Railroad at Jersey City.

Q. 2. How long have you been engaged in that duty?

A. Since the 1st of July last—1872.

Q. 3. How long in all have you been employed on a railroad, and what railroad?

A. I have been employed on the New Jersey Railroad for about 20 years. Since I first came there I have been away; I was in the government service; had charge of car repairs for nearly two years at Chattanooga, during the war.

Q. 4. As foreman of car inspectors at Jersey City, what, at the present time, and what, since the 1st of July, 1872, have been your duties?

A. My duties are to see that the cars that arrive are properly repaired; the western lines principally—western and Washington lines.

Q. 5. The cars of what companies, including the cars which formerly belonged to the New Jersey Railroad Company, compose these various lines which are under your charge?

A. The cars are principally composed of Pennsylvania Railroad cars, together with the Washington lines, the Camden and Amboy, and Philadelphia, Wilmington and Baltimore cars.

Q. 6. In the cars which you speak of as Pennsylvania Railroad cars, do you include the cars which formerly belonged to the New Jersey Railroad?

1466 A. No, sir; I have very little to do with those—not at all, scarcely.

Q. 7. What kind of double brakes are in use on the cars of these trains which you say are under your charge?

A. On the Pennsylvania cars the double-lever brakes are principally in use—in fact, on all of them; the Hodge brake, I believe, is the name of it.

Q. 8. How on some of the other cars which are under your charge?

A. On the Washington lines—those formerly that belonged to the Camden and Amboy and New Jersey Railroads are composed of the single centre-lever brake, and on the Philadelphia, Wilmington and Baltimore road the Stevens brake.

Q. 9. Do your duties as car inspector of these cars you have mentioned cause you to be familiar with the adjusting of these various brakes you have named?

A. They do.

Q. 10. Will you please state about how often on an average you find it necessary to adjust the centre-lever brakes in the cars which are under your charge in the Washington lines?

A. Well, I never kept a particular account. I should judge it was about once in two to three weeks.

Q. 11. When you do adjust them, what do you have to do to them?

A. Merely screw up the nuts of the connecting rods on the brake-bars or brake-beams.

Q. 12. When you screw up the nuts of these connecting rods on these brake-beams of a car, about how long does it take you on an average?

A. Five to ten minutes.

Q. 13. About how often on an average do you find it necessary to adjust the Hodge brakes which are under you charge?

1467 A. I couldn't hardly answer that question, because on the western lines our cars are gone from three to eight days, and I have generally adjusted them every trip they came in.

Q. 14. Do you consider it to be necessary to adjust the Hodge brake as frequently as this?

A. Well, it is necessary, or I should not do it.

Q. 15. If you are called upon to put on new brake-shoes, how much time does it take to do it on a car having a centre-lever brake, as compared with a car having the Hodge brake or the Stevens brake?

A. About the same time; I don't think there is any difference; I can put it on one as quick as on the other.

Q. 16. When you are required to put on to a car either new wheels or new brake-beams or new brake-shoes, which brake, at such times, requires the nicest adjustment, the centre-lever brake or the Hodge brake?

A. The centre lever brake requires the nicest adjustment, and is the one which we are most particular about.

Q. 17. But after the centre-lever brake is adjusted under the circumstances just inquired about, how often on an average do you say it requires to have its adjustment regulated?

A. Once in two to three weeks, I should judge.

Q. 18. Will you please state how the centre-lever brake holds the cars as compared with the Hodge brake or the Stevens brake?

A. From my personal knowledge I could not answer that question, for I have never broke on them only as to try the brake. It takes less time to apply the brake with the single centre lever than it does with the double-lever brake—that is, the Hodge brake.

Q. 19. With such experience as you have had in trying the centre-lever brakes, as you say, how do you think they hold the cars as compared with the Hodge brake and the Stevens?

A. I think they hold them just as well.

1468 Q. 20. You say you can apply the brake quicker with the centre-lever brake than you can with the Hodge brake? Will you please state why this is?

A. You have not so much chain to wind up; you can brake direct on to the brakes without taking up the slack of the chain at both windlass-shafts.

(Cross-examination waived.)

CORNELIUS VAN DEMARK.

Sworn to before me this 25th day of October, 1872.

T. B. BEECHER,
Notary Public, N. Y. County.

Deposition of John P. Van Doren, recalled on the part of the complainant.

Direct examination by M'r Cozzens:

Q. 1. You have heretofore testified in this case that you have charge of the cars constituting the New York and Washington through lines, running over the New Jersey, Philadelphia, Wilmington and Baltimore, and Baltimore and Ohio Railroads?

A. Yes, sir.

Q. 2. Please state whether, as a part of your duty in superintending and looking after the cars of these lines, you have to attend to the adjusting of the brakes upon said cars.

A. Yes, sir.

Q. 3. Please state what kinds of double-acting brake are the ones you have had charge of on those roads.

A. We have a centre-lever—I believe they call it the Tanner;
1469 I never call them by their names; and there is the Stevens—
two levers in each truck and a rod running from one truck to the other.

Q. 4. Will you please state about how often you have to adjust the "centre-lever" or Tanner brake on said cars?

A. Some cars we have run a month where we have not had to alter them.

Q. 5. Taking one centre-lever car with another, and one week with another, about how frequently on an average do you have to adjust the centre-lever brakes on said cars?

A. Not over two weeks at an average.

Q. 6. Not over once in two weeks?

A. No, sir.

Q. 7. About how frequently do you have to adjust the Stevens brakes on these New York and Washington cars on an average?

A. I don't think quite as often again. We have to oftener on account of the short curves on the road, which give us more trouble with the Stevens brake.

Q. 8. When you do adjust the centre-lever or Tanner brake not more than once in two weeks on an average, as you have stated, what is it that you do to it to adjust it?

A. Screw up the nut on the brake-beam a little—both trucks equally.

Q. 9. About how long does it take, ordinarily, to adjust the nuts on these two trucks?

A. About ten minutes; if they get chocked very tight it might take a little longer, but, as a general thing, about ten minutes.

Q. 10. Is there anything else than this that you have to do ordinarily in adjusting the centre-lever brakes?

A. That is all.

Q. 11. If you are called upon to put new brake-shoes on to cars having the centre-lever brake, does it or not take you any longer to 1470 put them on than it would with a car with any other kind of double brake on it?

A. About the same time.

Q. 12. Is the air-brake, or, as it is called, the Westinghouse brake, in use on any of the cars which form part of the New York and Washington through lines?

A. Yes, sir.

Q. 13. Is there any full train which runs in those lines for any part of the distance between New York and Washington which is equipped with the air-brake?

A. We have one; we have the Camden and Amboy cars together—which we have had on the morning line; we have had it so that those cars went out all with the same brakes.

Q. 14. How far do those cars run?

A. To Philadelphia.

Q. 15. Then, as I understand you, there are six cars which compose one of the New York and Washington air-line trains as far as Philadelphia with the air-brake on them?

A. They have been in some mornings, but we don't keep it regular. We have been short of cars and we have had to mix them up. It has run out several times when we could use sometimes four and sometimes five cars.

Q. 16. On these cars which have this air-brake, what form of double brake is the air-brake applied to?

A. To the centre-lever or the Tanner brake.

Q. 17. Please state how the air-brake works with the centre-lever double brake?

A. Just as well as the other; the hand-brake, I think, works better.

Q. 18. What do you mean when you say "the other"?

A. I mean the Westinghouse or the other; either one.

1471 Q. 19. What do you mean when you say that the Westinghouse brake works as well with the centre-lever double brake as it does with "the other"? What do you mean by "the other"?

A. I mean the Hodge brake.

Q. 20. Will you please state how the centre-lever or Tanner brakes hold the cars, as compared with the Stevens brakes?

A. On our trains they hold better; they do not have to have so much slack as on the other cars—on the double-lever or Stevens brakes—to run short curves.

Q. 21. And you say they hold better than the Stevens brakes?

A. Yes; on account of they do not have to have so much slack on the curves.

(Cross-examination waived.)

JOHN P. VAN DOREN.

Sworn to before me this 25th day of October, 1872.

T. B. BEECHER,
Notary Public, N. Y. County.

1472 TESTIMONY ON THE PART OF THE COMPLAINANT TAKEN AT JERSEY CITY, NEW JERSEY.

Deposition of Abraham Parmer, taken at Jersey City Oct. 26, 1872.

Direct examination by M'r Sayles in person:

Q. 1. What is your name, age, residence, and occupation?

A. Abraham Parmer; I am twenty-eight years old; residence, Jersey City, New Jersey; I am a brakeman on the Pennsylvania Railroad, running between New York and Philadelphia.

Q. 2. How long have you been brakeman on said road, and on what trains?

A. I have been seven years a brakeman on said road; on freight-trains, and on passenger; about three years and a half on passenger-trains—the last three and a half years.

1473 Q. 3. What kinds of brakes have been used on the passenger cars on which you have been brakeman?

A. I have used the Hodge brake, the single lever brake, and the Stevens brake.

Q. 4. Please state how the single lever brake compares with the Hodge brake and the Stevens brake in holding a train of cars.

A. The single lever brake and the Hodge brake is very near alike. The single lever brake works the easiest. The Stevens brake I don't like at all—it is not good for much.

Q. 5. Do you mean by the single lever brake the brake that is in general use on the New Jersey Railroad cars?

A. Yes, sir.

Q. 6. Are the Westinghouse air brakes used on any of the cars having on the Hodge brake or the single lever brake on the trains on which you have been brakeman?

A. Yes, sir; they are used on both.

Q. 7. You say the single lever brake you think works easier than the Hodge—do you or not mean when the Westinghouse brake is attached to it?

A. The single lever works the easiest when the Westinghouse brake is attached.

Q. 8. When the Westinghouse brake is not attached to either, which brake—the Hodge or the single lever brake—can you stop the train the quickest with, if there is any difference?

A. Well, one is as good as the other when the Westinghouse brake is not attached. The single lever brake does not require so much winding of the windlass as the Hodge. The single lever brakes work the easiest; that is, do not require so much winding up, when they are both in order. I like one as much as the other.

Q. 9. You say you do not like the Stevens brake; what appears to be the difficulty with it?

1474 A. They have to have too much chain to it, in the first place. Another thing, there is no lever to have any purchase on, and the rod is so long that it strikes the post generally before you can get the brake up. The post is the windlass shaft on which the chain winds.

Q. 10. Do you mean that there is no horizontal lever under the body of the car?

A. There is no lever on the Stevens brake at all; nothing but a long rod.

Q. 11. Are there not levers in the trucks where Stevens brakes are used?

A. No, sir; there are truck levers between the brake beams.

Q. 12. You, in speaking of the Stevens brake, say there is too much chain; do you or not mean by that that you have to wind up the windlass more than with the other brakes you have spoken of?

A. Yes, sir; you have to wind up the windlass more where there is more chain.

Q. 13. Have you or not noticed in working the Stevens brake that the chain in winding around the windlass so much would overlap the chain, or wind over the chain, and thus partly destroy the power of the brake?

A. Yes, sir; it does. I find when it lops over it binds and you cannot get it up.

Q. 14. Do you or not remember a brake being put on a passenger car on the New Jersey Railroad, numbered 93, some time last winter or spring, called the Tpringfield brake?

A. I do, and it was good for nothing.

Q. 15. Did you have occasion to brake any on that car while that brake was on it?

A. I had, once.

Q. 16. How did it work in stopping the train?

A. Didn't work very good. It is a brake I don't know much about. I never used it only one stop. It wouldn't hold. They didn't keep it on long.

1475 Q. 17. What train are you brakeman on now?

A. 9.30 a. m., out of here, Western and Philadelphia express, and the 1.30 from Philadelphia, through Washington express.

(Cross-examination waived.)

his
ABRAHAM + PARMER.
mark.

And being sworn and subscribed before me this 26th day of October, A. D. 1872.

J. N. BLAIR,
Master in Chancery of New Jersey.

Deposition of Ephraim F. Hall, taken at Jersey City, October 26, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. My name is Ephraim F. Hall; age, 43 years; residence, Newark, New Jersey; I am a carpenter by trade; I am now a car inspector on the Delaware, Lackawanna and Western Railroad, Morris and Essex division.

Q. 2. How long have you been employed on railroads, and in what capacities?

A. About 15 years, on different railroads; I used to work on the Erie road; I worked on passenger cars; building of cars. I worked on the Chattanooga and Nashville road, in Tennessee—about 1863 or 1864 I worked there; I worked for the government on this road; during the war I worked on the Louisville and Nashville, the Nashville and Chattanooga, and I think the Nashville and Northwestern Railroads.
1476 It was all under the government, and all one thing to me; I was there about a year, more or less.

Q. 3. What kind of brakes are used on the passenger trains on the Morris and Essex Railroad?

A. We have three different kinds of brakes there; the Stevens brake, the Hodge brake, and a centre lever brake.

Q. 4. How long have you been on the Morris and Essex road, and in what capacities?

A. About eight years. I first went to work at general repairs for about a month; was then put in as foreman of general repairs; was foreman about five years as near as may be; since then car inspector at Hoboken.

Q. 5. How long has the Hodge brake been used on the Morris and Essex road?

A. About six years, as near as I can remember.

Q. 6. What was the occasion of the Hodge brake being put on the Morris and Essex road?

A. It was in connection with the Loughridge steam brake.

Q. 7. What brakes were used on that road before the Loughridge brake was put on the cars?

A. We used the centre lever brake, and the Stevens brake; these were the two brakes we used.

Q. 8. Did you ever have occasion to apply those brakes in stopping at stations?

A. I have.

Q. 9. Please state which of those brakes you preferred?

A. I preferred the centre lever brake, for my part.

Q. 10. Why did you prefer that?

A. Well, I prefer them because there is less slack of the chain to be taken up to get a bearing of the brake; it's quicker applied, and it's less trouble to keep in repair; that is why I should prefer it.

Q. 11. In regard to holding the train in making stops at stations, how did the centre lever brake compare with the Hodge and Stevens brakes?

1477 A. Well, according to my judgment it was as good as either. I always found it so.

Q. 12. Please state about how often you have found it necessary to adjust the centre-lever brakes to keep them in good order?

A. On trains running all the time, about once in three weeks, with the natural wear.

Q. 13. When you do adjust them what do you have to do, and how long a time does it require to do it?

A. Well, I have to take off the bottom rod on each truck; it takes about ten or fifteen minutes; it's a short job.

Q. 14. About how often does the Hodge brake require to be adjusted to keep it in good working order?

A. It wants to be adjusted about once a week.

Q. 15. Will you please state why it is that the Hodge brake requires to be adjusted oftener than the centre-lever brake?

A. Because they have just twice as much slack to take up as there is in the centre-lever brake, and a little wear gives it just twice as much slack as the other.

Q. 16. What kind of brakes were used on the passenger trains when you were employed for the government, in Tennessee where you have spoken of?

A. The most of them were the centre-lever brakes that were then used; nearly all, except one or two.

Q. 17. Were these centre-lever brakes used on all the cars of the Louisville and Nashville road?

A. I can't say on all the cars, but on those we repaired they were; that is far as I can say; they were in general use on the road.

Q. 18. Is the Louisville and Nashville one of the most important roads in the South?

A. Yes. sir; I believe it is; so said, at any rate.

Q. 19. How well did the centre-lever brake work in holding the trains on the Southern roads you worked on?

1478 A. I believe they worked very well—at least, the brakeman said so—when they were in order.

Q. 20. In what capacity were you employed on these Southern roads you have spoken of?

A. I was what was called a gang-boss, or foreman of a gang of men repairing cars.

Q. 21. Did this employment, then, enable you to know how the brakes worked?

A. No, not personally; but only by the brakemen reporting when they came in on the trains. They generally reported when they came in.

Q. 22. Was it in the line of your employment, then, to learn how the brakes worked, and to learn when they were out of order and needed adjusting?

A. Yes; not directly but indirectly. There was a man to whom it was reported by the brakeman, and it came to me through him. This is the way on all roads.

Q. 23. When these reports came to you that the brakes needed repairing or adjusting, whose duty was it to order the brakes adjusted or repaired?

A. I had charge of a gang of men, and it was my duty to do it. When I was told that the brakes wanted repairs it was my duty to fix them. We never used the word "adjusting," but "repairs" covers everything. "Repairs" covers "adjusting." We don't use the word "adjusting." "Fixing" is the word we use.

Q. 24. How did the adjusting or fixing the brakes on the Southern roads on which you worked compare as to frequency with the adjusting or fixing the centre-lever brakes on the Morris and Essex road, as you have stated?

A. About the same. Not much difference between the two.

Cross-examination by M'r Whipple:

Cr. 1. As near as you can recollect, what number of passenger-
1479 cars with the centre-lever brakes on them were there in use when
you were employed by the government?

A. I don't know exactly the number, but as near as I can recollect about forty passenger-cars at one time. Sometimes not so many—they were burned up sometimes—but I think about forty.

Cr. 2. Did all these forty passenger-cars have the centre-lever brake applied to them?

A. I think the majority of them did, as near as my memory serves me.

Cr. 3. What brake was on the minority?

A. Well, they had a single brake on either end.

Cr. 4. From what road did the government take these cars with the single brake?

A. Well, I don't know. I can name some of them. Some were from the Louisville and Nashville road, and some were from the Nashville and Chattanooga.

Cr. 5. Do you know anything of the operation of the centre-lever brake on the cars of the aforesaid road other than what was told you?

A. No, sir; I have no way to know it. I had no way to know it. I didn't use them any more than to repair them in the shop, and when we repaired them we tried them to see if they were right.

Cr. 6. Did you as a boss of a gang of men make a personal trial of the brakes when repaired, or did you leave that work to your men?

A. I did; I generally did that myself.

Cr. 7. Did you try these brakes so repaired out on the road, for the purpose of checking the trains?

A. No, sir.

Cr. 8. Do you mean by adjusting the brakes, taking up the wear of the shoes by turning up the nuts on the brake beams?

A. Yes, sir; that is what I mean by adjusting the brakes, taking up the slack, we call it.

Cr. 9. You are obliged to take up the slack in the Hodge brake once a week, are you?

1480 A. Yes, sir; when the train is running steadily.

Cr. 10. And you have to take up the wear or slack of the centre-lever brake once in three weeks when the train is running steadily?

A. Yes, sir; that is about the time, as I am using them now.

Cr. 11. You say you are now using the centre-lever brake; is the connection from the windlass to the centre-lever and the truck-lever connection on a line with each other, or are the truck-levers connected with the centre lever at a short distance inward from the end of said lever?

A. One of the rods from the truck-lever is connected to the end of the lever in the centre of the car; the other end of the centre lever is connected to the windlass; the other rod, that runs from the other truck at the opposite end of the car, is connected between the end that is connected with the windlass and the centre-pin of the centre lever.

Cr. 12. What is the length of the centre lever?

A. It is about three foot long—two foot ten inches, or about in that neighborhood.

Cr. 13. In making the connections with this centre lever, less than three feet long, do you make them at the end of the lever?

A. We make the connection with the windlass or brake-shaft at the end of the lever.

Cr. 14. Where do you make the brake-shaft connections?

A. About half the distance from the end of the centre lever to the centre-pin the lever revolves on; the connections of the other half are the same, if it is a double brake.

Cr. 15. Is the centre lever used as a double brake on the passenger-cars of the Morris and Essex road? If so, to what extent?

A. I believe it not used there now. They have taken it off; they did use it.

Cr. 16. Why was it taken off?

1481 A. It was taken off to apply the steam-brake.

Cr. 17. You speak of using one centre-lever brake; on what car do you use it?

A. Smoking-car of the Delaware, Lackawanna and Western Railroad—broad guage.

Cr. 18. Do you run on the smoking-car as brakeman?

A. No, sir; I do not.

Cr. 19. Do you know anything of the operation of this one brake you have described?

A. Only from the baggage-master who used it.

Cr. 20. How were the connections made with the centre-lever brake when used by the Morris and Essex Railroad Company before applying the Loughridge brake?

A. They were connected by a lever in the centre of the car, and connected from each end to a rod running to the brake-shaft at each end of the car; they were about half way from the end to the centre of the centre lever, by a rod running to each truck-lever.

Cr. 21. Are there any cars on that road except the smoking-car you have named that has the centre lever on as you have described?

A. We have some box-cars, but no passenger-cars; we have one derrick-car that the centre lever is on.

Cr. 22. Are you quite sure that the connection of the truck-levers with the centre lever is equidistant between the end and the centre of the centre lever?

A. No, sir; I am not, for I didn't measure.

Cr. 23. How near to an equidistant to the two points named in the above question is the connection?

A. Couldn't tell you; the one I put on myself is as near equidistant as may be; of the rest, I don't know.

Cr. 24. How many inches should you judge the truck-lever connection was from the end of the centre-lever, as used on the Morris and Essex road before applying the steam-brake?

1482 A. I used to make them from 8 to 10 inches; about 8 inches on an average.

Redirect:

Q. 25. In adjusting the centre-lever brake when first attached to a car—and the Hodge brake when first attached to a car—which requires the nicest adjustment?

A. The centre-lever brake requires the nicest; we are more particular to get it exact.

Recross:

Cr. 25. Is the Hodge brake self-adjusting in its character, or does it have to be adjusted from time to time after it has been applied to a car?

A. It has to be adjusted, or fixed as we call it—the slack taken up to keep in good order.

EPHRAIM F. HALL.

Sworn and subscribed before me this 28th day of October, 1872.

WILLIAM A. BLAIR,
Master in Chancery of New Jersey.

Deposition of George W. Brown, recalled for complainant, taken at Jersey City, October 28, 1872.

Direct-examination by M'r Cozzens:

Q. 1. Please state what is the length between windlass-shafts of the passenger-cars of the New Jersey division of the Pennsylvania Railroad on which you are employed?

A. About 50 feet to 55 feet, or somewhere thereabouts; all according to the length of the cars.

1483 Q. 2. What is the distance between the ends of the body of the cars, excluding the platforms?

A. About 48 feet to 50 feet, according to the car.

Q. 3. How many wheels in the trucks under the passenger-cars of the said New Jersey Railroad?

A. Twelve wheels under the old cars—six wheels in one truck.

Q. 4. What is the length of these six-wheeled trucks?

A. About 9 feet.

Q. 5. Please state what is the length of the four-wheeled trucks under the passenger-cars of the Pennsylvania Railroad that come into Jersey City?

A. About 9 feet 4 inches to 9 feet 6 inches.

Q. 6. In the centre-lever brakes used on the passenger-cars of the New Jersey Railroad what is the length of the centre levers?

A. About 45 inches.

Q. 7. In these centre-lever brakes on the New Jersey Railroad what is the length of the connections from the centre-levers to the tops of the truck-levers when the said truck-levers are placed at the inside ends of the trucks?

A. About fifteen feet, more or less.

Q. 8. What is the length of these same connections when these levers are placed at the outside ends of the trucks?

A. About twenty-*two* feet. It might be a little more or a little less, according to the car.

Q. 9. Please state which brake, the centre-lever brake or the Hodge brake, when first applied to a car, requires the nicer adjustment.

A. The centre-lever brake, I think.

Q. 10. After the centre-lever brake is attached to a car, about how often does it require adjustment to keep it in order when the car is in use?

A. About every three weeks it ought to be, to keep it in order. When the brake-shoes wear off we have to take up the slack.

1484 Q. 11. In adjusting the brake at these times, or taking up the slack, what is done to it?

A. We screw up the nuts on the connecting-rods that connect the two brakes together with the truck-lever.

Q. 12. About how long on an average does it take to do this?

A. From ten to fifteen minutes.

Q. 13. How does the centre-lever brake compare with the Hodge brake in reference to the quantity of slack-chain to be wound up in applying the brakes?

A. The Hodge brake has more slack-chain than the centre-lever brake.

Q. 14. Does this fact give either of the brakes any advantage over the other in the application of them to the wheels; and, if so, to which one does it give the advantage?

A. To the centre-lever.

Q. 15. What is the effect of this advantage in the centre-lever brake in reference to the application to the wheels?

A. There is less chain to wind on the shaft. It takes effect sooner after applied.

Q. 16. Which brake, then, can be made to apply to the wheels the quickest?

A. The centre-lever brake, I think.

Q. 17. How does the centre-lever brake compare with the Hodge brake in regard to holding the trains when applied?

A. That I can't say. Never had the experience to try them. Never was brakeman.

Q. 18. What experience have you in reference to the matter of the effect of the centre-lever brake in holding the cars?

A. I have often seen it applied when the trains are in motion, and the effect is very good in taking the trains up. It pulls as well as any brake I ever saw used.

1485 Q. 19. Do you remember a brake known as the Springfield brake, put on car 93 on the New Jersey Railroad a few months ago, having two chains winding around each windlass shaft?

A. I remember a brake was put on in our shop. It was applied in the way spoken of with two connecting rods on each truck and with two chains running to each windlass shaft.

Q. 20. Did you have anything to do with fitting up or adjusting the brake on that car?

A. I did. It came under my charge as assistant foreman of the shop.

Q. 21. Please state how nice a piece of work it was to adjust that brake when it was fitted up.

A. It was a particular job to get the chains running to the windlasses the correct length, so as to make them both act on both trucks at the same time.

Q. 22. About how much longer did it take to adjust the Springfield brake on that car than it does to adjust the centre lever brake when it is first applied to a car?

A. Well, I couldn't say exactly how long. It was one we never had anything to do with before. Probably it took half as long again to put that one on, it being something I never saw before.

Q. 23. Please state how much, if any, play is allowed in the cars of the New Jersey Railroad between the swing-beams and the inside cross-timbers between which the swing-beams hang.

A. Not anything at all. We fit them very tight, so that we often drive them in with a sledge.

Q. 24. If, by wear, there should come to be some play, what, if anything, do you do when the cars come in for repairs?

A. We always overhaul the trucks and fit the swing-beams, furr out the castings and make the swing-beams fit tight.

Q. 25. Suppose by use there comes to be some play when the
1486 cars are running on the road; what, if any, effect would this play
have on the operation of the centre lever brake?

A. It might make the chain running to the windlass a little longer when applying the brake; that is all.

Q. 26. Would it or not, in your judgment, make any difference in the effect of the centre lever brake upon the wheels?

A. I don't think it would. It would give as much power as if the swing-beam was tight, only you might have to wind a little more chain on the shaft.

Cross-examined:

Cr. 1. At what point of the centre lever, as used on the New Jersey cars, is the truck-lever connection made?

A. At the end of the centre-lever.

G. W. BROWN.

Sworn and subscribed before me this 28th day of October, 1872.

WILLIAM A. BLAIR,
Master in Chancery of New Jersey.

Deposition of Samuel Thomas, recalled by complainant, taken at Jersey City Oct. 28, 1872.

Direct examination by M'r Cozzens:

Q. 1. Please state what are your duties now on the New Jersey Railroad, at present leased by the Pennsylvania Railroad.

A. My duties are to see that the cars are in proper condition for the road. I am car-inspector. Have been car-inspector there about 14 years.

Q. 2. What does this seeing that the cars are in proper condition include, or require you to know?

1487 A. It includes all cars that come in the depot at Jersey City except the Washington air-line.

Q. 3. In keeping all these cars in good order, what part of the cars do you have to attend to?

A. Every thing about them.

Q. 4. Among these various cars under your charge what form of double-acting brakes are there on them?

A. There are centre levers, and some have two cross levers—one near each truck.

Q. 5. Please state what experience you have in seeing or knowing about the application and effect of the brakes on the cars when running into the station here in Jersey City, or when the cars are being "drilled."

A. I am right there with them all the time and see them coming in and going out. I see them when they are being "drilled."

Q. 6. Does this enable you to know how the brakes hold the cars when applied?

A. I can see when a brake is applied whether it is holding or not, when the car passes me.

Q. 7. How does the centre lever brake compare with the brake having two cross levers near the trucks as to the holding of the cars when applied?

A. The centre lever brake holds. I don't see but what it holds as well as the double lever, and it is a great deal less trouble to take care of.

Q. 8. You say "less trouble to take care of"; please state about how often on an average the centre lever brake has to be adjusted or have its slack taken up when a car is in use?

A. That depends on whether the nuts rattle off, but if the nuts remain on tight we have to tighten them up in from two to three weeks.

Q. 9. State what nuts you refer to as sometimes rattling off—where are they placed?

A. Nuts on the connecting rods connecting the two brakes in the truck.

1488 Q. 10. State whether these nuts are more liable to rattle off than on any other form of double-acting brake?

A. They are not; no, sir.

Q. 11. When you adjust or take up the slack of the centre lever brake every once in two or three weeks as you have stated, what do you do to it?

A. We screw up those nuts that I have just spoken of—on the connecting rods.

Q. 12. How long does it take to do this on an average?

A. If the nuts work easy, it don't take five minutes.

Q. 13. Taking one time with another, and one nut with another, how long does it take on an average?

A. It wouldn't take over ten minutes on an average.

Q. 14. Suppose you have a new brake-bar or new brake-shoes to put on, how does the time required to put them on compare as between the centre lever brake and the brake having the two cross levers?

A. I don't know as there is any difference in that.

Q. 15. Do you remember some months ago that a brake known as the

Springfield brake, having two chains winding on each windlass-shaft, was put on passenger-car number 93 of the New Jersey Railroad?

A. I recollect of a brake being put on of that kind with two chains, but I don't know the name of it, don't know what they called it.

Q. 16. Do you know how long that brake was continued in use on that car?

A. I don't think it was on very long.

Q. 17. While said brake was in use on that car, if the brakemen found fault with it to whom was it their duty to make complaint of it?

A. They complained to me; I was car-inspector.

1489 Q. 18. State whether, while this two-chain brake was in use on that car, the brakemen did complain to you about it?

A. Yes, sir; they complained.

Q. 19. What did they complain of in regard to it?

A. They complained of its working hard—wouldn't hold, and didn't hold the car.

Cross examination by M'r Whipple:

Cr. 1. In what month in the year 1872 did this two-chain brake first come under your observation as inspector of cars at Jersey City?

A. I couldn't say what month, but when it was turned out of the shop it came under my inspection.

Cr. 2. In what month do you think it was turned out of the shop?

A. Well, I think it must have been—I couldn't say what month—it must have been pretty well the fore part of the year.

Cr. 3. What month do you think is pretty well the fore part of the year?

A. In January or February; I think it must have been some where about then; I know it wasn't on a great while.

Cr. 4. While said brake was on said car 93, did you at any time take up the wear of the brake-shoes?

A. I didn't; but I think my men did. I am not positive; they often take these brakes up and I don't know it. I recollect that the brakemen complained of this brake, and I told them that if it wouldn't hold, I didn't know how to fix it to make it hold; I recollect that.

Cr. 5. Did the brakemen ever complain of other brakes not holding, that is to say the centre lever brake?

A. Yes, sir.

Cr. 6. Did you, while the double-chain brake was on car 93, give any personal attention to it by way of adjusting it and keeping it in order?

1490 A. I don't know that I did—any more than any of the rest of the cars; I don't recollect.

Cr. 7. Was said brake on car 93 some two or three months?

A. I don't think it was on three months.

Cr. 8. Why was the brake taken off, and where was it taken off, and for what purpose?

A. I think the brake was taken off at M'r Baker's shop, but am not positive. I think I understood that the brake was taken off because it worked hard—wouldn't hold.

Cr. 9. What brake was put on in its place—was it the centre lever brake or the double lever brake?

A. It was the centre lever brake that was put on, I think. I think it is on yet.

Cr. 10. Might it not have been the double-lever brake and the air brake applied to that?

A. I know the air brake is on the car, but I am not positive whether it is the double-lever or the single-lever brake.

Cr. 11. Then, was not the double-chain brake taken from car 93 that the Westinghouse air-brake might be applied to the same?

A. It seems to run in my mind that that car was taken to the shop that the double-chain brake might be taken off—and M'r Baker had the air-brake put on in its place.

Cr. 12. Do you know anything about the double-chain brake as used on car 93, other than what has beeen told you or reported to you by brakemen?

A. I do not; only by the brakemen and drillmen.

Cr. 13. Are not these brakemen and drillmen in the habit of reporting to you about other brakes not holding?

A. Yes, sir.

Redirect examination by M'r Cozzens:

1491 Q. 20. When they report to you about other brakes—for instance the centre lever brakes—not holding, what do you do to the brakes?

A. Sometimes we tighten up the connecting rods, and sometimes we put on new shoes.

Q. 21. Is this what comes under the head of adjusting—or taking up the slack of—the centre-lever brake?

A. Yes, sir; as a general thing.

Q. 22. Is there any difficulty in doing it with the centre-lever brake?

A. No, sir.

Q. 23. Why was it—when the brakemen complained to you that the two-chain brake on car 93 would not hold—that you told them that if it wouldn't hold, you didn't know how to make it hold?

A. The shoes were as close to the wheels as they ought to be, and if it wouldn't hold then, I didn't know how to fix it; the shoes were good.

Q. 24. When you said this, was there anything the matter with the adjustment of the brake?

A. I don't know that there was; if there was, I would have had it fixed. I didn't see anything the matter with the adjustment.

Q. 25. When the brakemen sometimes report to you that the centre-lever brake does not hold, and you have adjusted it in the manner stated by you a few answers above—what more, if anything, is there needed to make it hold?

A. I don't know that there is anything more particularly.

Q. 26. You have said that the two-chain brake was as you thought put on in the fore part of 1872—January or February. May it not have been put on in December or November, 1871?

A. I think since I spoke about its being on in 1872, that it was not on when M'r McDermond was here; he had charge of the general inspection for five months—he began to take charge the 11th of January, 1872. I never paid any attention to when that brake was 1492
put on, for I did not suppose that I would ever be interested in it. I don't recollect that it was on—I don't think it was at that time—whilst M'r McDermond had charge.

Recross-examination by M'r Whipple:

Cr. 14. How long did M'r McDermond have charge from the 11th of January?

A. Till the first of June.

Cr. 15. Was it after the first of June, 1872, that this two-chain brake was put on car 93?

A. I think not.

Cr. 16. When do you think it was put on?

A. I think, if I recollect right, it was put on in cold weather.

Cr. 17. Did this two-chain brake on 93 hold the car as a brake ought to hold, at any time after it came out of the shop?

A. Well, I don't know; I couldn't say.

Cr. 18. What do you think about it?

A. It might have held; all I know is they complained to me—the brakemen and drillmen.

Cr. 19. And this complaint comes to you about other brakes from the brakemen and drillmen?

A. Yes, sir.

Cr. 20. And do you mean by other brakes the centre-lever brake, and the double-lever brake?

A. Yes, sir.

Redirect examination by M'r Cozzens:

Q. 27. When any complaints come to you about the centre-lever and double-lever brakes, do you ever have any difficulty in adjusting them so that they will work well?

1493 A. I have made the centre lever work good, and I have made the double lever work what they call good. No, I don't have a great deal of trouble in making them work well generally. Sometimes they complain that they don't work well after I have fixed them, and then we generally tighten them up a little more on the nuts or slack up a little.

Q. 28. Do you apply the last part of this answer to both the centre-lever and double-lever brakes?

A. Yes, sir.

Q. 29. When the brakemen complained to you about the two-chain brake not holding—as you have stated—could you not, if it had needed it, have done to it all that you do to the centre-lever and double-lever brakes when the brakemen complain of them?

A. Of course we could—we could have put on new shoes, new irons, or tightened them up.

Q. 30. But were you ever able to adjust that brake and keep it up so that the brakeman would say that it worked well?

A. I don't recollect of ever hearing them say that it worked well.

Recross-examination by M'r Whipple:

Cr. 21. Did it ever appear to you that the same mode of adjustment applicable to the centre-lever brake and double-lever brake would throw the two-chain brake out of adjustment?

A. No, sir, it has not appeared to me.

Cr. 22. While the two-chain brake was on car 93, did any person or persons give you any instructions how to adjust said brake in order to make it hold as a brake ought to hold a car?

A. I don't recollect that any one ever did.

1494 Redirect examination by M'r Cozzens:

Q. 31. Did you ever do anything to the two-chain brake to try to throw it out of adjustment?

A. No, sir; I did not.

Q. 32. Did you do all you could to keep it in adjustment?

A. Just as much with that as with any of the rest of the cars; I did do all that I could to keep it in adjustment—I ordered it done.

Q. 33. Was it after all this that the complaints were made to you by the brakemen that it wouldn't hold ?

A. Yes, sir.

Q. 34. Please state how many trains come in and go out of the Jersey City depot—on the New Jersey Railroad—in a day, that are under your charge as car inspector of the Pennsylvania Railroad ?

A. They are all under my charge that run between here and Philadelphia except the Washington air-line. There are one hundred and twenty-three trains per day marked on the time-table.

Q. 35. How many men are under you ?

A. About sixty men—sixty or seventy.

Recross-examination by M'r Whipple:

Cr. 23. What did you do personally by way of adjusting the two-chain brake on car 93 ?

A. I don't recollect that I did anything myself; I ordered it to be taken care of—tightened up or slackened up—as I thought it required.

Cr. 24. Of the 123 trains that run out of the Jersey City depot per day, how many cars on an average compose said trains—should you judge ?

A. From five to ten; some of those same cars make a good many trips.

1495 Cr. 25. Of all these cars—be they more or less—how many have the centre-lever brake applied to them ?

A. I think, at present, most of the cars have the double-lever brake on.

SAMUEL THOMAS.

Sworn and subscribed before me this 28th day of Oct., A. D. 1872.

W'M A. BLAIR,
Master in Chancery of New Jersey.

1496 FURTHER TESTIMONY ON THE PART OF THE COMPLAINANT, TAKEN AT JERSEY CITY, N. J.

Deposition of Charles Watts, taken at Jersey City, Oct. 29, 1872.

Q. 1. What is your name, age, residence, and occupation ?

A. Charles Watts; age, twenty-seven years; residence, Rahway, New Jersey; I am a depot master at Jersey City, for the Pennsylvania Railroad.

Q. 2. How long have you been depot master for said road at Jersey City ?

A. Since the first of January, 1872.

Q. 3. After you became depot master on said road, January 1st, 1872, was there a brake having two chains attached to each windlass on a passenger-car belonging to the Pennsylvania Railroad Company, and running into the depot where you are depot master ?

A. There was, but I can't remember when it was put on, whether before I was appointed depot master or after.

Q. 4. Do you remember while that brake was on that car having an engine attached to the car; and if so, about when was it; and 14097 after the engine had been so attached, what, if anything, did you order done with the car ?

A. I remember the engine being attached to the car. I can't remember exactly when it was. I remember its being a very nice day. I think it was in April. After the engine was attached to the car I ordered the brake applied, and the ratchet set, and then ordered the car to be pulled from the straight track on to the curve and there stopped.

Q. 5. When the brake was applied to the car, what kind of a track was the car standing on?

A. On a straight track.

Q. 6. Was the car still or in motion when the brake was applied to it on the straight track?

A. Still.

Q. 7. How hard were the brakes applied at this time?

A. I can't tell that; if I had put it on myself I should have known it.

Q. 8. So far as you could judge, how hard were they applied?

A. The brake was put on ordinarily, the same as a brake usually is.

Q. 9. How near were you to the car at this time?

A. I should judge, about ten or twelve feet.

Q. 10. What pulled the car from the straight track on to the curve?

A. A shifting engine.

Q. 11. Before the car passed from the straight track on the curved track, had the brakes been applied?

A. The brake was applied and remained applied from the straight track on to the curve.

Q. 12. Was the brake applied then while the car was in motion and before the car struck the curve?

A. The brake was applied.

Q. 13. What was the effect upon the wheels of the car while
1498 the car was passing, with the brakes applied as you have stated,
from the straight track on to the curve?

A. The wheels of the front truck slid when they struck the curve; the wheels of the rear truck did not slide.

Q. 14. How far on tothe curve was the car drawn before it was stopped?

A. I think the car stood directly on the curve, so that both trucks were on the curve.

Q. 15. Is that double-chain brake still on that car?

A. No, sir; a Westinghouse brake has been attached to the car.

Q. 16. To your best recollection, about how long after the car was drawn on this curve, as you have stated, was this two-chain brake taken off?

A. I think about two or three weeks.

Q. 17. Please state how this curve on which that car was tried as you have described, compares as to sharpness—that is, shortness of radius—with curves on the main line of the New Jersey Railroad between Jersey City and Philadelphia?

(Question objected to, as it is assumed that the witness has no knowledge of the radius of curves on said road.)

A. I should judge it was about the same; if anything a little sharper.

(Answer objected to in absence of the proof.)

Q. 18. State whether, in your judgment, there are any of the curves on the main line of said road which are as sharp as this curve referred to?

A. I don't think there are.

Q. 19. How do the curves at turnouts on said road compare in sharpness with said curve?

A. From what I know of the turnouts I don't think they are quite as sharp.

1499 **October 30th, 1872.**

Q. 20. Was any other curve proposed for the trial of this car 93 than the curve on which you did order it tried, as stated? If so, please state what other curve was proposed, and why the car was not tried on such other curve.

A. It was proposed to try the car on the curve in the city of Newark, between the Centre-street bridge, over the Passaic River, and the Centre-street depot. We intended to send the car out on the two o'clock train, but on account of its being so late we could not do so without detaining the train, and for this reason the car was not tried on any other curve.

Q. 21. Who wished the car tried on this curve at Newark?

A. M'r Barker, the division superintendent, suggested the car being tried on the curve at Newark.

Q. 22. Who suggested trying the car on the curve on which it was tried?

A I did.

Q. 23. Was M'r Sayles present at this time; and, if so, did he say anything about these curves, and if he did what was it?

A. He was present. I don't positively know whether he said anything about the curve or not.

Q. 24. While this car with this double-chain brake on it was used on the New Jersey Railroad, what was the average number of cars with other brakes on them which were run in the same train with it?

A. From five to eight was about the average.

Cross-examination by M'r Whipple:

Cr. 1. When did you first make the acquaintance of M'r Sayles, the complainant in this case?

A. I can't tell exactly. I think some three or four weeks previous to the trial of the car, as near as I can recollect.

1500 Cr. 2. Please state the circumstances under which said acquaintance was made?

A. I was introduced to M'r Sayles by the division superintendent, M'r Barker, who, I think, informed me that M'r Sayles wished to have the brake on that particular car tried, or tried just as M'r Sayles should direct.

Cr. 3. Why was not the trial made at the time of your first acquaintance?

A. This car was at that time one of our extra passenger-cars, and was absent at the time, or not at Jersey City.

Cr. 4. How long thereafter before said trial was made?

A. As near as I can recollect, two or three weeks.

Cr. 5. Had there come to your knowledge that said brake was on a car of your road before being informed of the fact by M'r Sayles?

A. I did not know there was such a brake on the car until I was informed by M'r Sayles.

Cr. 6. Did there any complaint come to you from any quarter in reference to said brake before the trial of the same?

A. I do not think there did.

Cr. 7. Did there any complaint come to you after the trial and up to the time it was taken off?

A. I do not remember of any.

Cr. 8. Under whose instructions did you act in ordering out an engine in order to make a trial of said Springfield brake?

A. I did not receive any instructions to order out an engine.

Cr. 9. Did you receive instructions to make a trial of the brake with an engine?

A. No, sir; I received instructions to have the car put on a local train.

Cr. 10. From whom?

A. M'r Barker, division superintendent.

1501 Cr. 11. What was your authority for making a trial of said brake on a curve in the yard at Jersey City?

A. I took my own responsibility.

Cr. 12. At whose request did you take this responsibility?

A. No one's request. It was my own suggestion that the car be tried on that curve.

Cr. 13. Had you previously had any conversation with M'r Sayles in relation to alleged defects in said brake when tried on a curve?

A. Yes, sir; I did.

Cr. 14. What did he state to you in said conversation in reference to the operation of said brake on curves?

A. The import of his conversation was to the effect that the brake-chain would break, lever bend, or the truck jump the track.

Cr. 15. And was it this statement that led you to try the experiment?

A. No, sir.

Cr. 16. What then did lead you or influence you in your decision to try said brake on said curve?

A. An engine being already attached to the car, and a curve on the same track, I ordered the car pulled on the curve, not at M'r Sayles's suggestion, but, as I thought, to avoid the trouble of running the car at some other time.

Cr. 17. At which end of the car was the brake applied—the end nearest the curve, or at the end farthest from it?

A. At the end next the engine and nearest the curve.

Cr. 18. Did you notice, before submitting the brake to the trial aforesaid, whether the brakes were properly adjusted so that the brakes would bear equally, or nearly so, on both trucks when the brake was applied and run on a straight track?

1502 A. I made no examination of the brake whatever. I noticed the man apply the brake and set the ratchet.

Cr. 19. May not the turnbuckles in the long rods, one of which connected the brakes of the opposite truck from where the power was applied, have become loose, and the long connection elongated so that little or no power could be communicated to the truck farthest from the end where the brake was applied?

A. I know nothing about the construction of this brake, and, therefore, cannot say.

Cr. 20. Had there been but a single brake on the forward truck of this car next the engine, would the same result probably have followed on applying the brake on a straight track and then running it on a curve?

A. I cannot say positively. I think there is more probability of the wheels sliding on the track where it was tried than on the main line.

Cr. 21. Do you think that the fact that the rear truck of the car was connected with the forward windlass, would have anything to do with causing the wheels of the forward truck to slide when they struck the curve, the brakes of said forward truck being connected to the same windlass?

A. I cannot say.

Cr. 22. Having drawn the car through said curve with the brakes applied to the end nearest the engine, did you draw or back said car through said curve with the brakes applied at the opposite end to see if the wheels of the other truck would slide when they struck the curve?

A. The car stopped directly on the curve. I can't say whether the car went through or back. The brake was not applied on the other end of the car.

Cr. 23. Do you think, all things considered, that the brake had a fair trial at the time you hauled said car onto the curve and there stopped?

A. As to that, I cannot say.

1503 Cr. 24. Did you, or not, state to M'r Whipple in a conversation with him, that you did not think the brake had a fair trial, or language to this effect, referring to the trial aforesaid instigated and brought about by M'r Sayles?

(The wording of the last part of the question objected to by complainant.)

A. I do not remember of saying to M'r Whipple that the car had not a fair trial; but I think I mentioned to M'r Whipple that the wheels would be more likely to slide on the track where the trial was made.

Cr. 25. Some time after this trial, did M'r Barker direct you to have a brakeman try said car and test its holding qualities?

A. I do not remember.

Cr. 26. Did you not state thereafter that you had given directions to a brakeman to try said brake, and that he had not up to the time of inquiry by M'r Whipple made any report?

A. I do not remember of giving any such order.

Cr. 27. Did or not M'r Whipple come into M'r Barker's office two or three times after the aforesaid trial and request a trial of said brake to determine whether it would or would not hold a car as a brake ought to?

A. I have some slight recollection now of M'r Whipple making such a request.

Cr. 28. Was said request ever complied with, or any effort made on your part, or M'r Barker's, to comply with said request?

A. The request was not complied with, for the reason, as near as I can recollect, on account of the Westinghouse brake being attached to that car.

Cr. 29. Was not the Westinghouse brake applied to said car at least two or three weeks after said request was made?

1504 A. I think not.

Cr. 30. Are you positive that the Westinghouse brake was on car 93 when M'r Whipple made the request of M'r Barker to try the Springfield brake on said car?

A. Since our conversation here now about this matter, I am positive that the Westinghouse brake was not applied to said car at the time M'r Whipple made the request to M'r Barker to have the brake applied.

Redirect:

Q. 25. Did M'r Whipple call more than once about this matter?

A. He did call more than once; he called twice.

Q. 26. State whether the Westinghouse brake was on the car at each time of his calling?

A. The Westinghouse brake was attached at the last time of his calling only; not at the first.

Q. 27. Why, then, was the request which he made to have the brake tried not complied with at his first call?

A. I do not distinctly remember, but think it was on account of there being no train suitable for trying the brake without delaying important trains; there are only two or three trains on which we could conveniently try it.

Q. 28. Was there any objection or opposition that you know of to the trying of the brake?

A. Nothing more than that referred to in my last answer.

Q. 29. You have said, on your cross-examination, that you did not know that this two-chain brake was on car 93 until M'r Sayles told you of it. Was there any special reason why you should know it previous to his telling you?

A. I do not know of any.

Q. 30. Was it your business to know what brake was on car 93?

1505 A. No, sir; as long as the brake was in working order and not reported in bad condition.

Q. 31. Whose business was it to know what brake was on car 93 and to see that it was not in bad condition?

A. John McDermond; at that time our car inspector.

Q. 32. Who became general car inspector after John McDermond?

A. Samuel Thomas.

Q. 33. Is Samuel Thomas car-inspector at the present time?

A. He is.

Q. 34. Might the brakeman have complained about the working of this brake on car 93 without your knowing it?

A. Yes, sir; he might.

Q. 35. Did this car 93 run in any regular train while this two-chain brake was on it?

A. Not between the time that M'r Sayles called my attention to the fact that there was a double-chain brake on that car and the time the Westinghouse brake was attached.

Q. 36. During this time, in what train did the car run?

A. As an extra car, always on the rear of the train, or nearly so.

Q. 37. While running with this two-chain brake on it, was it every day at Jersey City; if not, state some of the lengths of time it would be away from there?

A. It was not at Jersey City every day. I can't form any idea of the lengths of time it would be away. It might be away a week and sometimes not more than an hour. Sometimes it would run to Newark and be cut off and put on the end of another train and brought right back.

1506 Q. 38. Why did you suggest for the trial of this brake the particular curve at Jersey City where it was tried rather than any other curve at Jersey City?

A. Because the car stood directly on that track. Also, I did not have the time to spare in trying it on any other curve.

Q. Did you suggest this curve because it was sharper than any other curve, or because it was not so sharp as any other curve at Jersey City?

A. I did not.

Q. 40. Was there any other reason whatever for suggesting this curve for the trial except that it was the most convenient curve that presented itself to you at the moment?

A. No, sir; there was no other reason, except, as I have already stated, that I did not have time to put it in a train to send it to Newark.

Q. 41. Did M'r Sayles express any wish as to what curve this brake should be tried on; if so, what did he say?

A. I do not remember of M'r Sayles making such a request.

Q. 42. Do you remember his expressing a wish to have the car sent to Newark to have the brake tried on a curve there?

A. Yes, sir; I think M'r Sayles was very anxious to have the car go there.

Q. 43. Did you go from your office in the depot to where car 93 was for any purpose; if so, for what purpose?

A. M'r Sayles and I left my office to go in search of the car, when I found it was too late to put the car on the 2 o'clock Newark train.

Q. 44. When M'r Sayles and you left your office to search for the car, what train did you intend to put the car into?

A. The two o'clock train for Newark and Perth Amboy. This car 93 was to be cut off at Newark—not being required to go any further on that train.

1507 Q. 45. In what direction, to the right or left, did this curve at Jersey City on which you tried this car, run?

A. To the right.

Q. 46. And in what direction did the curve at Newark, on which M'r Sayles was anxious to have the brake tried, run?

A. To the left.

Q. 47. At the time of the trial, when the brakeman on the car applied the brakes, did they or not appear to hold on both trucks on the straight track?

A. It seemed to me that, from the way the engine was laboring, the brakes were holding. You can tell from the exhaust of the engine whether the brake holds or not.

Q. 48. At any time before or during the trial, did you see M'r Sayles, or anybody else, do anything whatever to the rods of the brake?

A. I did not.

Q. 49. Was there anything in the nature or condition at this time of the curve or the rails on which the brake was tried why the wheels of one truck rather than of the other should slide on it?

A. I do not know of any.

Recross:

Cr. 31. By what name is the brake called in general use on the cars of the New Jersey road?

A. I don't know.

Cr. 32. Are they the centre-lever brake, so called.

A. I believe they are called the centre-lever brake.

Cr. 33. Did you ever know of the wheels of a centre-lever brake sliding on a curve?

A. I have known the wheels of both trucks slide with it on a curve.

Cr. 34. Did you ever know of the wheels of one truck sliding and not those of the other truck, when the cars are running on a curve under the brakes?

1508 A. Yes, sir; I have—on curves, on straight tracks, up grade and down grade, under all circumstances.

Redirect:

Q. 50. With what kind of brake attached to the centre-lever brake have you seen what you state in your last preceding answer?

A. The Westinghouse brake.

Q. 51. Have you seen the wheels slide with the Westinghouse brake applied to the brake on the Pennsylvania cars—that is to say, with the Hodge brake?

A. I have seen them slide. I know I have seen them slide on a straight track. I have seen them slide repeatedly coming in stations. It is a very common thing to see them slide.

Recross:

Cr. 35. Before the Westinghouse brake was ever applied to a car running into Jersey City, did you ever see the wheels of one truck slide on a curve, while the wheels of the other truck did not, the car having a centre-lever brake on it?

A. I have.

C. WATTS.

Taken, sworn to, and subscribed this 30th day of October, A. D. 1872, at Jersey City, in said district, before me.

ISAAC ROMAINE,
United States Com'r, District of New Jersey.

1509 *Deposition of David H. Baker, taken at Jersey City, Oct.* 30, 1872.

Q. 1. Are you the same David H. Baker who has been examined before in this case on the part of the complainant?

A. I am.

Q. 2. You are general foreman, I believe, of the car department at Jersey City of the New York division of the Pennsylvania Railroad?

A. I am.

Q. 3. Has there been within a few months past a brake called the Springfield brake tried upon a passenger car on the New Jersey Railroad—now called said New York division? If so, under whose direction was the fitting up of that brake done, and about when was it done?

A. There has. The fitting up of the brake was done under my direction, from instructions I received from M'r S. M. Whipple, now present. It was done before January, 1872.

Q. 4. Please state how well the putting of this brake on the car and the fitting it up was done.

A. I consider it was done in a workmanlike manner, and as well as it could be done.

Q. 5. When it was done, how nearly equally did the brake shoes bear on all the wheels of the car when the brake was applied?

A. They bore about equally, as near as I could judge, and as near as could be done.

Q. 6. In this Springfield brake, when it was on the car, what was the distance on the short chain and rod between the windlass shaft and the top of the truck lever into which said rod hooked?

A. About four feet.

Q. 7. What were the respective lengths of the long and short arms of the truck levers?

1510 A. I should judge it was about twenty seven or twenty eight inches from the top hole to the second hole, and about six and a half inches from the second hole to the bottom hole.

Q. 8. About what was the length between the windlasses of the car on which this brake was put and about what was the weight of the car?

A. About fifty-three feet from one windlass to the other. I can't give the weight of the car, only by estimation. I should estimate that it weighed between seventeen and eighteen tons.

Q. 9. Did you at any time see the Springfield brake on this passenger-car tried on a curve at Jersey City? If so, will you please state who was present at the time it was so tried?

A. I did. M'r Sayles, the complainant, Charles Watts, and several others were present when the brake was tried. I can't now recollect the names of the others.

Q. 10. Please state what was done with the car at this trial.

A. It was in motion when I saw it first, with the brakes applied, on a straight track, and a locomotive was drawing it on to a curve. When the first truck got fairly on the curve, the wheels began to slide in that truck. I don't know whether all the wheels slid; two of them did, any way. When it got fairly on the curve the car was stopped. M'r Sayles came around the car on the side where I was. I was from fifty to a hundred feet from the car. I saw M'r Sayles put his foot on the back brake-bar of the rear truck and move it; I saw it move. I saw them draw the car through the curve on to a straight piece of track beyond.

Q. 11. Were both trucks of the car on the curve when you saw M'r Sayles move the brake-bar of the rear truck with his foot?

A. I don't think the hind truck was altogether on the curve. It may have started on.

Q. 12. Please state what this fact—that M'r Sayles was able to
1511 move the brake-bar of the rear truck with his foot at this time—
indicated as to the brakes of that truck.

A. Indicated that there wasn't a great deal of pressure on it.

Q. 13. You say you saw the car drawn out through the curve on to the straight track beyond; when it reached the straight track beyond what was the effect on the brakes?

A. The wheels all turned then; there was no sliding then. The wheels only slid at one point in the curve.

Q. 14. How did the holding of the brakes when the car had been drawn through the curve on to the straight track beyond compare with their holding when you saw them applied on the straight track before the car had been drawn on to the curve at all?

A. I couldn't see that there was any difference at all. I left it after that.

Q. 15. When you saw this car with the brakes applied on the straight track, both before and after the car had been drawn through the curve, were the wheels of the car sliding or turning?

A. They were turning before and after they were drawn through the curve.

Q. 16. How many of them were turning, both before and after they were drawn on to the curve?

A. All of them—twelve wheels.

Q. 17. Please state what is your opinion as to the practical utility of a car-brake for regular use on railroads, which—when a car having the brake applied on a straight track is drawn on to a curve—would operate as you have described this Springfield brake to have operated in this trial.

A. I don't think, if I had the say, I would use a brake of that kind if I could get any others. I would not use a brake of that kind if I could get any others.

Q. 18. Is that Springfield brake running on the road now?
1512 A. Not to my knowledge.
Q. 19. Did you have anything to do with the taking it off?

A. I did not. I didn't know it was off until M'r Whipple told me it was off.

Q. 20. You have heretofore in this case testified that the Tanner or centre-lever brake has been for many years in general use on the cars of the New Jersey Railroad; please state when it first went into general use on said road.

A. If I recollect aright, I think it was in 1851 that it went into general use—1851 or 1852.

Q. 21. And have they been on that road ever since, and are they in use there at the present time?

A. They have been used ever since, and are in use there at the present time.

Q. 22. During this period how have they worked?

A. I believe they have worked satisfactorily. If they hadn't they wouldn't have kept them on to this time.

Q. 23. You say you believe they have worked satisfactorily; is there any doubt about it?

A. I know they have worked satisfactorily; there have been no complaints of them.

Q. 24. State how—in this long experience with the Tanner brake—you have found the brake to work when the cars with the brakes applied pass from a straight track on to a curve, and vice versa.

A. I have never seen any difference.

Q. 25. What is the effect of the Tanner brake as to the direction in which the trucks are drawn when the car is in motion and the brakes are applied?

A. I should say the effect would be to draw the trucks toward the centre of the car.

Q. 26. In the cars of the New Jersey Railroad, built and repaired under your charge, how much, if any, play is there between the sides of the swing-beams and the inside faces of the truck-timbers between which the swing-beams hang when you send the cars out of the shop? 1513

A. We don't mean there shall be any play—only enough to allow the swing-beams to move up and down.

Q. 27. How much will this "enough to allow the swing-beams to move up and down" amount to?

A. Less than an eighth of an inch.

Q. 28. After the cars have run some time without going into the shop, how much play do the swing-beams sometimes get from wear?

A. From three eighths to half an inch; we never allow them to get more than that.

Q. 29. When they get as much play as this, what do you do to them?

A. Furr out the wear-irons so as to make them tight again; what we call tight—nearly so.

Q. 30. In the practical use of the Tanner brake on the New Jersey Railroad, what, if any, difference is there in the pressure of the brake-shoes upon the two trucks when, in consequence of the car not having been repaired for some time, the swing-beams have got considerable play—say three-eighths or half an inch play?

A. I don't consider there would be any difference—providing the brake was properly adjusted.

Q. 31. Please state if the Westinghouse air brake is at the present time in use on the passenger-cars of the New Jersey Railroad; if so, how generally?

A. Most all the passenger cars on the road have them; there are very few exceptions. We are putting them on as fast as we can.

Q. 32. With what form of brake is the air brake applied on said New Jersey Railroad cars?

A. The Hodge and Tanner both.

Q. 33. How many of the cars of said New Jersey Railroad have the air-brake on with the Tanner brake?

1514 A. I can't tell the exact number; there are between forty and fifty; there may be more than fifty—or a few more than forty. We are putting the air-brake on with the Tanner brake as fast as we find a car that has not got one on.

Q. 34. How well does the Westinghouse brake work on these cars with the Tanner brake?

A. It works satisfactorily; there are no complaints.

Cross-examination by M'r Whipple:

Cr. 1. What proportion of the cars that come into Jersey City with the Westinghouse brake on has the application made through the Tanner brake?

A. I should think there was one-third.

Cr. 2. Through what brake is the application of the air-brake made to the remaining two-thirds?

A. Hodge brake, so far as I have seen.

Cr. 3. Did the order come from the Pennsylvania road to you at any time to change all the Tanner brakes to the Hodge in applying the Westinghouse air-brake?

A. It did; and I changed one, and then I got the order countermanded. They let me go on putting on the Westinghouse brake with the Tanner brake.

Cr. 4. In applying the Westinghouse brake to the cars of the Camden and Amboy Railroad, is the Tanner brake retained, or is the Hodge brake substituted?

A. On all the cars on which I put the Westinghouse brake the Tanner brake is retained. I have seen it applied with the Hodge brake.

Cr. 5. When the Westinghouse brake is applied to Camden and Amboy cars at Philadelphia or Bordentown, is the Tanner brake retained or discarded and the Hodge brake put in its place?

A. I believe that the Hodge brake is now put in its place.

1515 Cr. 6. From what point to what point does the so-called Jersey road run—formerly known as the New Jersey Railroad and Transportation Company, and what is the length of it?

A. It runs from Jersey City to some two or three miles beyond New Brunswick. I think its length is about thirty-four miles.

Cr. 7. On what car of the New Jersey road did you put the Springfield brake?

A. I think it was car number 93.

Cr. 8. Was that the number of the car that M'r Whipple obtained an order from M'r Jackson, superintendent, to apply the brake to; if not, what was the number of the car?

A. That was the car that I was authorized by M'r Jackson, superintendent, to put it on. M'r Whipple represented to M'r Jackson that there was a car, number 21, in the shop (a new car); but he did not represent to M'r Jackson that it was a new car. He (M'r Jackson) supposed, from the number, it was an old car. I explained to M'r Jackson the situation of the car. He told me to put it on just what car I saw fit, as that car (21) was finished, and they wanted to use it.

Cr. 9. Did M'r Whipple leave your shop, some time last December, with the expectation that you would apply the Springfield brake to car number 21, then in the shop; and did he expect that you would make the application that week, or the one following, or had you reason, from his conversation, to believe that he expected the brake would be applied as indicated in the fore part of the question?

(Objected to by counsel for complainant.)

A. I don't know what his expectations were, but I objected to his putting the brake on that car, as it was a new car and I did not wish to alter the brakes.

1516 Cr. 10. Did not M'r Whipple thereafter obtain from M'r Jackson, the superintendent, an order, notwithstanding your objections, to put said brake on car number 21?

A. I do not recollect whether it was an order or a communication from M'r Jackson. I do not know how it read. I think he brought me a letter from M'r Jackson.

Cr. 11. Did not that communication authorize you to put said brake on car 21?

A. I don't recollect exactly how that communication read at this time.

Cr. 12. Did you put said brake on at the time M'r Whipple expected you would have it ready for his inspection and approval on his return to Jersey City from Washington?

A. I don't know what his expectations were. I put it on. A few days after he called, and found it wasn't on the car he expected it was on. I inquired at the hotel where he, or somebody else, told me he was staying. They told me he hadn't been there in a day or two.

Cr. 13. Did M'r Whipple exercise any personal supervision over the application and trial of said brake to car 93, as applied by yourself?

A. He wasn't there personally when I put it on, and he found no fault with it afterwards, when he saw it was on; not to me.

Cr. 14. In applying said brake to car number 93, did you put turnbuckles in the long rods?

A. I did.

Cr. 15. And check-nuts on said rods back of the turnbuckles?

A. I did; according to his instructions.

Cr. 16. When said brake was taken out for trial on the track, under the direction of M'r Sayles, the complainant in this case, was the brake applied by the windlass at the end of the car nearest the curve on to which it was drawn by the engine or at the opposite end?

(Question objected to as stating an error in asserting that M'r Sayles directed this trial.)

1517 A. The man stood on the end of the car nearest the curve on to which it was drawn, with the brake-wheel in his hand. I suppose he was applying the brake from that end. There was nobody on the other end.

Cr. 17. Is there any doubt but that the brake was applied from the end at which the man stood?

A. Not in my mind there isn't.

Cr. 18. Do you know that M'r Sayles, or some other person, did not lengthen the long rod, by means of said turnbuckles, before this trial was entered upon, so that the rear truck would have little or no pressure upon it when the brake was applied, while the forward truck would have its brake applied through its connection almost to the sliding point?

A. I did not see any one do it, nor did I examine it to see if it was done.

Cr. 19. Had such been the case, as the question seems to indicate, would the brakes of the rear truck have little or no power on them, while the forward truck would have the brakes thoroughly applied?

A. It would have that tendency.

Cr. 20. Was M'r Whipple present at this trial spoken of in your direct examination of the Springfield brake on the straight track and the curve?

A. I did not see him there.

Cr. 21. What is the radius of the curve on which this trial of the Springfield brake was made?

A. I don't know anything about it.

Cr. 22. Are all the tracks in the yard at Jersey City more or less covered with grease from the drippings of cars and engines standing on them?

A. At times they are.

Cr. 23. Do you think it is a proper place to try the qualities of any brake?

A. I don't see why it shouldn't be. If one truck would slide, the other would slide, so far as the grease on the track is concerned.

1518 Cr. 24. Do you think that the aforesaid trial of the Springfield brake was in all respects a fair one?

A. If I had been opposed to the brake, I should have wanted to have been there myself. I had nothing to do with the trial. I accidentally saw it. I did not see enough of the trial to judge if it was a fair one, nor did I take interest enough in it to judge.

Redirect:

Q. 35. What kind of a car was this car, number 93, on which you put the Springfield brake?

A. It was considered one of our first-class passenger-cars.

Q. 36. Was there any reason whatever why a Springfield brake on car number 93 should not work in all respects the same, and as well, as if put on the new car, number 21?

A. Not any. It would have worked as well on one car as on the other.

Q. 37. State how closely you followed M'r Whipple's instructions to you about how to put the brake on when you put it on car 93.

A. As near as I could do. I believe, exact, almost, in every respect.

Q. 38. How nearly of the same dimensions and weight are cars 93 and 21?

A. They are pretty nearly alike. I should judge car 93 is two feet longer than car 21, and they are about the same width and weight.

Q. 39. Please state what was your opinion as to how the Springfield brake would work when applied on a car on a straight track, and then made to pass, with the brake applied, from the straight track on to a curve, before you saw the trial you have testified about.

A. It was always my opinion that it wouldn't brake equal on the trucks.

1519 Q. 40. In what respects, if any, did the working of the brake when you saw it on this trial differ from your previous opinion about it?

A. It corresponded just with my opinion.

Recross:

Cr. 25. How much service had the wheels of car 93 performed at the time the Springfield brake was applied to it—as near as you can judge?

A. I can't tell anything about how much work they had done. The wheels were in good order or we would have taken them out.

Cr. 26. Were the wheels new at the time said brake was applied?

A. They were not; some of them may have been new.

Cr. 27. Were the wheels new on car 21 as it stood in the shop last December?

A. They were.

Cr. 28. Had you applied said Springfield brake to said car 21—having first weighed the iron of which the shoes were composed, and then weighed the iron of the shoes of another car with the Tanner brake applied—said car of the same weight, with new wheels, and had the two cars been coupled together and run in a regular train until the shoes were worn out on both cars, and the remaining iron of the shoes been weighed on each car, and it had been found that the Springfield brake had worn out the same number of pounds of iron that the Tanner brake had under the same circumstances—would you or not have come to the conclusion that so far as the stopping of either of the cars was concerned the Springfield brake was as good for this purpose as the Tanner brake?

A. I don't know as I have any theory about that. That is too much of a mixed up question for me to answer. If one brake will slide
1520 the wheels and another won't, of course the one that slides the wheels won't wear the blocks as much as the other—but one man may brake more on one car than he does on another.

Cr. 29. Assume that one brakeman is to operate the brakes on the two cars as fitted up in the foregoing question, and run together till the shoes are worn out on each car, and it is found by actual weighing that the shoes so worn out have consumed as much metal as the others—other conditions being the same to both brakes—would or not in your judgment one brake be as efficient as the other in holding a car?

A. No; I should think not. In the first place, you may so arrange a brake that all the wear may come on one truck going one way—braking from one end—and going the other way and braking from the other end all the wear come on the other truck, and wear just as much metal as the brake on the other car that operates uniformly on all the wheels, and may show a wear of the same amount of metal at the end—if there is a possibility for two cars to use up the same amount of metal, which I don't think there is, even with two cars with the same brake on.

Cr. 30. Is or not the efficiency of any brake measured by the amount of metal consumed in the use?

A. I never heard of any such measurement; that is a new measurement to me.

Cr. 31. Is it possible to stop a railroad car by the means of brakes in which iron to iron is used and not consume metal; under that, I mean metal in the brake-shoes?

A. If you apply the brakes until the wheels slide, the brake-shoes will not wear.

Cr. 32. Assume that the wheels do not slide in the application of the brake, and then what is your answer?

A. It is impossible to do it. If two pieces of iron wear together they wear off.

1521 Cr. 33. Which brake in your judgment is doing the most efficient service in stopping a car—a brake that consumes half an ounce of metal in the stopping, or one that consumes three-quarters of an ounce in stopping; assuming that the wheels do not slide in either case?

A. That is a thing I don't want to decide on and won't decide on. I have never seen it tested.

D. H. BAKER.

Taken, sworn to, and subscribed this 29th day of October, A. D. 1872, at Jersey City, in the district of New Jersey, before me.

ISAAC ROMAINE,
United States Com'r, District of New Jersey.

1522 FURTHER TESTIMONY ON THE PART OF THE COMPLAINANT TAKEN AT JERSEY CITY, N. J.

Deposition of S. B. Stull, taken at Jersey City, Nov. 8, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. S. B. Stull; I am twenty-eight years old; I reside in New York City; I am a brakeman on the Pennsylvania Railroad.

Q. 2. How long have you been brakeman and on what trains?

A. I have been brakeman about two years on that road, part of the time between Jersey City and New Brunswick, and a part of the time between Jersey City and Philadelphia. I have been brakeman on the Philadelphia line about one year and three months.

Q. 3. What kind of brakes are used on the cars where you have been brakeman during the last two years?

A. Well, different kinds. There are three different kinds of 1523 brakes. The New Jersey cars have one kind which have a centre lever; the Pennsylvania cars have no cross levers; the Philadelphia, Wilmington and Baltimore, and Baltimore and Ohio cars have a brake with two upright levers in each truck, and long rods connecting the brakes between the trucks. Some of the New Jersey cars and the Pennsylvania cars now have the air-brake attached.

Q. 4. Which of these three brakes you speak of do you prefer?

A. I think I prefer the brake in the New Jersey cars.

Q. 5. Please state why you prefer these brakes.

A. The reason I prefer this brake is, because we do not have so much winding on the windlass to get the brakes to take hold, and the springs on the brake-beams are not so stiff as those on the Pennsylvania cars, and I think they hold them just as well, if not better. On the Philadelphia, Wilmington and Baltimore cars there is too much chain to wind up, so that it overlaps itself and destroys the power of the brake.

Q. 6. Does, or not, what you have stated in reference to these different brakes apply to these three different kinds of cars, before the air-brake was attached?

A. It does.

Q. 7. You say the air-brake has been applied to the New Jersey cars and the Pennsylvania cars; which of the two brakes, the centre-lever brake on the New Jersey cars, or the two cross-lever brakes on the Pennsylvania cars when the air-brake is attached, work the easiest by hand?

A. The New Jersey cars.

Q. 8. Have you often noticed these cars with the three different kinds of brakes attached being stopped at stations?

A. I have.

Q. 9. Have you or not noticed the wheels sliding when the train 1524 was being stopped at stations with the different kinds of brakes applied? If so, please state fully what you have noticed.

A. I have seen one pair of wheels slide and none of the rest. I have often seen the four wheels of one truck slide and none of the rest. I have seen the four wheels of each truck slide—this applies to each of the three kinds of brakes attached to the cars. I think there is no difference in sliding; one is as liable to slide as the other.

(Cross-examination waived.)

S. B. STULL.

Sworn and subscribed before me this 8th day of November, A. D. 1871.

W'M A. BLAIR,
Master in Chancery, of New Jersey.

1525 TESTIMONY ON THE PART OF THE COMPLAINANT, TAKEN AT WILLIAMSBURGH, NEW YORK.

Deposition of Henry H. Farnum, j'r, taken at Williamsburgh, Nov. , 1872.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. The name you have, Henry H. Farnum, j'r; age, 28; residence, Port Jervis, N. Y.; my occupation, chief engineer of South Side Railroad of Long Island, and have been chief engineer there for about three years.

Q. 2. Please state, if you know, the radius of the curve on the main track of the South Side Railroad of Long Island, at the Bushwick station, nearest to the depot building.

A. The curve is irregular and the average radius is five hundred and seventy-three feet (573).

Q. 3. What is the radius of that part of the curve nearest the depot?

A. The curve is shorter at that end, and I should think it was about five hundred feet (500).

1526 Q. 4. Please state the radius of the first curve west of Richmond Hill, on the South Side Railroad of Long Island.

A. Twenty-eight hundred and sixty-five feet (2,865).

Q. 5. What is the radius of the curve at Jamaica station on said road?

A. Six hundred and fifty feet (650).

Q. 6. What is the radius of the respective curves at the Y, at Valley Stream, on said road?

A. The radius of the curve on the west arm of the Y, which is the curve towards or nearest Bushwick, is seven hundred and thirty feet (730); and the radius of the curve on the east arm of the Y, which is the curve farthest from Bushwick, is five hundred and twenty-one feet (521).

Q. 7. Please state whether all these curves which you have testified about are in the main line of the road and are run over by the passenger trains of said road?

A. They are, with the exception of the two on the Y, which are a part of the Far Rockaway Branch of the road, over which passenger-trains are run throughout the year by the South Side Railroad Company.

Cross-examination by M'r Whipple:

Cr. 1. What are your means of knowing that the radii of the several curves to which you have testified in your direct examination are correct?

A. The road has been surveyed throughout its entire length—and its branches as well—entirely under my direction, and these statements of the radii are taken from the surveys and maps.

Redirect:

1527 Q. 8. Going from Bushwick how many of these curves that you have testified about turn in the same direction?

A. They all curve the same way; that is, to the right, going from Bushwick east.

H. H. FARNUM, J'R.

Deposition of William H. Weightman, taken at Williamsburgh, Nov. 26, 1872

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. William H. Weightman; age, 27; residence, Jersey City, N. J.; place of business, New York City; occupation, draughtsman.

Q. 2. How long have you been draughtsman, and what has been the nature of your draughting?

A. Since the summer of 1863; and in machinery of all kinds, more especially steam machinery; from 1863 to 1869 serving in the Novelty Works, New York, both in the shop and in the drawing-room, partly as apprentice, and partly as regular workman in both departments. Have also been engaged as draughtsman in the machinery department of the United States revenue and coast survey services.

Q. 3. Were you present at the trial of certain brakes on a car on the South Side Railroad of Long Island a few days ago?

A. I was, on different days, between 14th and 23d (inclusive) of November, 1872.

Q. 4. Please explain what kind of a car it was, and what kind of brakes you saw tried on said car.

A. The car was what was called a first-class passenger car on the road, marked as "Ladies' Car No. 33." The brakes that were
1528 attached to the car were the brake called the "Springfield brake,"
and the brake called the "Tanner brake."

Q. 5. State whether you yourself measured the different parts of these brakes, and also many of the different dimensions of the said car.

A. I did.

Q. 6. What was the length of that car between the bumpers?

A. Fifty-three feet.

Q. 7. Please state, if you know, the distance between the journals in the trucks in that car.

A. Six feet between centres.

Q. 8. You say you saw what is called the "Springfield brake" tried on that car. Please state, if you can, the length of the rods and chains, and also the lengths of the truck levers and their proportions in what was called the "Springfield brake."

A. I measured these lengths and found that the longer connection measured 37 feet 7 inches, with 20½ inches of chain at one end and 21½ inches of chain at the other end of the car. The shorter connections measured 3 feet 7 inches, with 19½ inches of chain at one end of the car and 20½ inches of chain at the other end of the car. The levers measured, at the longer end, 26⅛ inches, while the shorter end measured 5⅞ inches, making a total of 32 inches length between extreme centres. There were two levers to each truck. There were two long rods and chains—one running from each windlass to the opposite truck, and two short connections—one running from each windlass to the lever of the nearest truck. In each of the long rods there was a turnbuckle placed for the purpose of adjustment. The windlass shaft was 1½ inch in diameter; the windlass wheel was 16 inches in diameter.

Q. 9. Did you see the "Springfield brake" adjusted after it was attached to said car? If so, please state how it was done.

1529 A. I did see it adjusted. The windlass was wound up and the brake put on, previously having put one-quarter inch strips of iron between the shoes and the wheels for the purpose of feeling the pressure of the shoe, by inserting a bar in the opening. When the pressure was not equal in both trucks the turnbuckles in the longer rods were screwed up or slackened till the adjustment was equal and the pressure was exact on the wheels of both trucks. I did the final adjusting myself, and saw that the pressure was equal on the wheels of both trucks. The pressure of the shoes on one pair of wheels of each truck was a little less than on the other pair of the same truck.

Q. 10. After the brake was thus adjusted what was done with said car?

A. The car was drawn out upon a straight track by an engine; the brakes were applied at one end of the car; it was then backed onto a curve and the pressure of the shoes upon the wheels tested.

Q. 11. Please state what the effect of the brake was upon the wheels; first on the straight track where it was tried, and also when run upon the curve.

A. On trying the pressure of the shoes upon the wheels, on the straight track, it was found to be the same on both trucks. On the car being stopped the wheels slid on both trucks; I mean, one pair of wheels on each truck slid. The car was then backed on a curve, with the brakes on the same as when stopped, and all the wheels on one truck slid, while those on the other truck ran comparatively loose. Those wheels on the truck nearest the windlass, from which the power was applied, slid, while those farthest from the windlass ran loose. The car was then backed upon a straight track—the brakes applied on this straight track at the opposite end of the car—and drawn onto the curve. It was then found that the wheels nearest the applied windlass were loose, and those furthest from the applied windlass were
1530 tight. One pair of wheels on the tight truck slid. The curve on which this was tried was the one nearest the Bushwick depot buildings, on the main track of the road.

Q. 12. What was then done with the said car?

A. The car was then backed into the shed and the trial postponed, because it was train time.

Q. 13. What was next done with the car with the Springfield brake on?

A. On the next trial the car was drawn out by the locomotive onto a straight track, the brakes readjusted so that the shoes bore equally on both trucks. I looked to the adjustment myself. We then started off on the road, stopping at a place called Richmond Hill, where there is a curve which runs to the right in reference to the direction in which the car was going. The brakes were here applied, on the straight track, before stopping, and upon examination we found that the pressure was greatest on the truck nearest the windlass where the brake was applied, and was quite loose on the farther truck. The car was then started ahead and backed down again, with the brakes applied on the straight track at the opposite end of the car, with the same result, viz: that the brakes on one truck were tight, and on the other truck were loose, although not quite so prominent as at the Bushwick depot, this being a much larger curve. The car was then drawn on the road to

Jamaica, the brakes applied at the usual stopping-place at that station and upon watching the wheels, those on the truck nearest the applied windlass slid, while those on the truck at the further end of the car ran quite free. This was on a pretty sharp curve. The car was then drawn ahead ahd backed down, the brakes being applied from the other end of the car, with the same result as before. We then went on to Valley Stream, where there are two curves forming a "Y." The brakes were applied, and the car drawn forward and backed, with the same
1531 result as at Jamaica, on both of these curves. In all instances where the curve ran the same way, whether the brakes were applied at one or the other end of the car, the wheels of the same truck slid. We then returned on the road to Bushwick, where we tried the brakes applied on a straight track and found that they were considerably out of adjustment, whether applied at one or the other end of the car.

Q. 14. What was next done with the brakes on said car?

A. These brakes were taken off.

Q. 15. What brake was then put on the car?

A. The "Tanner brake," so called.

Q. 16. How were the levers of the Tanner brake arranged on the car?

A. Two of the same truck levers were used on this as had been used on the Springfield brake. The same windlass wheel and shaft were used as in the other. The truck levers were placed in the end of the truck nearest the end of the car and lay at the same angle as in the Springfield brake. The centre lever measured four feet between outer centres and two feet six inches between inner centres—the inner centres being nine inches inside of the outer ones. The windlass rods connected with the outer centres of the centre lever and the truck levers connected with the inner centres of the same.

Q. 17. What was then done with said car?

A. The car was drawn out on the straight track, the brakes adjusted by screwing upon a nut on the connecting-rods between the brake-bars of the trucks. The car was then run on the straight track and the brakes applied, and all the wheels of both trucks slid. The car was then run on to the same curve above mentioned, viz, the one nearest the Bushwick depot building—the brakes being still on and all the wheels sliding as before when on the straight track. The car was then backed
1532 down and run on to the curve the reverse way, with the brakes applied from the other end of the car while on the straight track, when all the wheels on both trucks again slid—both on straight and curved track. The brake-levers of the trucks were then removed and arranged on the inside ends of the trucks between the brake-beams and the king-bolts, as seen in the drawings of the Tanner patent—the tops of the levers being connected as before with the centre lever.

Q. 18. After the levers were so arranged what was then done and what was the result?

A. The brake was first tried on the straight track and found to be properly adjusted, the locomotive then attached, and the brakes applied on the straight track and drawn on the curve—the same curve above mentioned, viz, the one nearest the Bushwick depot building—all the wheels sliding on both straight and curved track. We then drew the car off on to a straight track and backed down, applied the brakes at the opposite end of the car on the straight track, when all the wheels of both trucks again slid on both straight track and curve.

Q. 19. What was then done with the car?

A. It being then train time, the car was drawn off and returned to the shed.

Q. 20. What was next done with the car ?

A. On the next day but one after, the car was drawn out on a straight track—the locomotive being attached—the brakes tried, and found to be properly adjusted, when we started off on the road to Richmond Hill, where the brake was tried on the curve before mentioned and found to slide all the wheels, when the brake was applied at either end of the car. We then went to Jamaica, and applied the brake on the same curve that we had applied the Springfield brake, and we found that all the wheels slid when the brakes were applied. We then went on to Valley Stream, and tried the brakes on both curves of the "Y"—and 1533 from each end of the car—when we found that all the wheels slid in all the trials. We then returned to Bushwick, stopping on the way at a long stretch of straight track, where the brakes were applied at both ends successively with the same result as before, all the wheels sliding. On arriving at Bushwick, the brakes were applied at both ends alternately and found to be still in proper adjustment. The car was then returned to the shed.

Q. 21. Did you see the Hodge brake tried on the same straight track and curve near the Bushwick station as the other two brakes were tried on ?

A. Yes ; I did.

Q. 22. What was the result ?

A. The break was applied to car No. 12 on same road—a passenger-car. The brakes were applied on the straight track and run on to a curve, when two wheels of each truck slid on both stright track and curve. The car was then run on to a straight track and the brakes applied from the other end with the same result, two wheels from each truck sliding.

Cross-examination by M'r Whipple:

Cr. 1. In the application of turnbuckles to the Sringfield brake, were there check-nuts on the rods contiguous to said buckles for the purpose of making them permanent and fixed ?

A. There were not.

Cr. 2. After the first trial of said Springfield brake, as testified to by you, the car was taken into the shed and afterwards was taken out again, and you say the break was readjusted. Why was it necessary to readjust it if it was properly adjusted at the time of said first trial ?

A. Because on trying the pressure of the shoes on the wheels of both trucks, it was found to be unequal.

1534 Cr. 3. How do you account for this inequality after so short a trial, seeing that all the parts of the brake were iron to iron ?

A. I can only account for it from the difference in the length of the rods through which the brake levers are operated and the extra strain on the chains while running over curves, that the brake is easily put out of adjustment.

Cr. 4. May there not be a remedy for this inequality by giving the long rod an advantage over the short one in adjusting the brake, that is to say, making the long rod more taut than the shorter one, which can easily be done with the turnbuckles ?

A. There may not, for the reason that when you make the longer rod more taut than the short one you make the pressure of the shoes on the wheels unequal, and proper adjustment demands that the pressure on the wheels of both trucks shall be equal.

Cr. 5. Please state whether the same brakeman applied the brakes in all these trials, both of the Springfield and Tanner brakes?

A. The same man applied the brakes in all parts of the trials at Bushwick. At other times regular road brakemen were employed.

Cr. 6. What instructions, if any, were given to the brakemen before entering upon these trials?

A. There were no instructions given, to my knowledge.

Cr. 7. In testifying to the operation of the Springfield brake on the curve, you say that the brake on one truck was tight while the brakes on the other truck were loose; do you mean by "loose" that there was little or no power on the wheels of the truck?

A. They were so loose that they exerted very little, if any, influence on the stoppage of the car.

Cr. 8. How much influence did the brakes exert on the stoppage of the car on the truck of the same car in which the brakes were tight while the brakes were loose on the other truck?

1535 A. So little influence that the momentum of the car carried the wheels sliding along the track.

Cr. 9. When you came to operate the Tanner brake on the same car, the influence was enough to slide the wheels of both trucks; was this so?

A. It was.

Redirect:

Q. 23. Please state whether you yourself turned the turn-buckles you have spoken of; and, if you did, state whether they turned hard or easy, and whether any check-nuts were needed to keep the turn-buckles permanently in place after being moved.

A. I did. They turned quite hard, requiring a stick of two feet length to turn them easily. The thread was newly cut also. Check-nuts were not needed to keep the turn-buckles in place, in my judgment, during the period of the trial.

Q. 24. In the trials, to which you have referred, with the Tanner brake, when the first sliding of any of the wheels took place, how many wheels in each truck slid?

A. The two wheels nearest the outer end of the car on each truck in all cases slid first.

Q. 25. Please state which of the two—the Springfield or the Tanner brake—required the longest time to adjust the brake-shoes properly to the wheels.

A. The Springfield brakes considerably longer.

Recross:

Cr. 10. Did you at any time inspect the turn-buckles in the long rods of the Springfield brake, so that you can testify that by continued jarring of said rods, they were not elongated for want of a check-nut back of each turn buckle?

1536 A. Before starting at any time with the Springfield brake, I examined the adjustment. On the route I looked to see that nothing had got out of order at the different stopping-places, and on the return I could see no symptoms that the longer rods had been lengthened or shortened by the turning of the turn-buckles.

Cr. 11. Did you put a mark on the screw, and on the turn-buckle, so that you could at any time determine whether the long rods had been lengthened by the continued jarring of the same?

A. I did not, as I could not have told by that means, from the fact that, had the turn-buckles turned exactly once, twice, or three times, the marks would have been in the same position with reference to each other.

Cr. 12. Had you made a mark with a file across the two arms of the turn-buckle at the end of the screw projecting within the turn-buckle, and had the turn-buckle turned round by continued jarring, would not the screw have receded from that mark more or less?

Q. It would.

Cr. 13. Do you know it did not recede, consequent upon the jarring or some other cause?

A. I know it did not recede enough to, in my opinion, affect the brakes.

Cr. 14. Do you know it did not recede at all?

A. I do not.

Redirect:

Q. 26. Upon what do you found your opinion that it did not recede enough to affect the brakes?

A. Upon the fact that it took at least one quarter inch in the movement of the turn-buckles to affect the brakes in adjusting them; so it should take at least that much movement to put them out of adjustment, and I should at least have noticed a movement of one-quarter of an inch in the turn-buckles.

1537 Recross:

Cr. 15. Do you know of your own knowledge that the turn-buckles did not, from jarring or other causes, recede at least a quarter of an inch, and thereby elongate the rods to that extent?

A. I know and am satisfied that they did not.

W. H. WEIGHTMAN.

Deposition of A. P. Doane, taken at Williamsburgh, Nov. 27, 1872.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. Name is A. P. Doane; age, 47; residence, Brooklyn; occupation, master-mechanic of South Side Railroad of Long Island.

Q. 2. How long have you been master-mechanic of that road?

A. Four years.

Q. 3. Were you ever engaged on any other railroad before coming to the South Side road; if so, what other road, in what capacity, and how long?

A. I have been. I was on the Oswego and Syracuse, Long Island, New York Central, and New York and Erie Railroads. I was master-mechanic of the Oswego and Syracuse road about four years, and two years on the Long Island road. I was foreman and draughtsman of the New York Central, at Syracuse, for fifteen years.

Q. 4. Please state whether you were present between the 14th and 23d days of November, 1872, at certain trials of brakes on the aforesaid South Side Railroad?

1538 A. I was.

Q. 5. What kind of brakes were the chief subjects of these trials?

A. The Springfield and Tanner brakes.

Q. 6. Please state what kind of a car it was upon which these brakes that were tried were put.

A. A first-class passenger-car, No. 33.

Q. 7. Will you please state what was the condition of the railroad track at the times of these trials?

A. The track was dry.

Q. 8. Please state what was done with the car in trying these brakes, speaking first of the Springfield brake trial.

A. The brake was put on and an engine connected with the car and run out upon the straight track. The brake was adjusted, and applied upon the straight track on the eastern end of the car; that is, the end farthest from Bushwick. Then we ran on to the curve in the Bushwick yard nearest the depot buildings, the car running to the west. On the curve one set of the brakes were found to be tight, and the other comparatively loose.

We then run the car upon the straight track again and applied the brake to the other end of the car. We ran on to the same curve again with the same results; that is to say, the brakes were tight on the same truck as before and loose on the same truck as before. When the brakes were applied on the straight track the brakes were tight on both trucks, a pair of wheels on each truck being slid when the brake was thus applied on the straight track; but when the car was run on to the curve the wheels of the truck at the east end of the car slid—both pairs of wheels—while the wheels were revolving upon the other truck. The car was then put in the house because it was train-time.

The next time we had a trial, we hitched an engine on to the car and drew it out of the house on to a straight track, and then adjusted 1539 the brakes. What I mean by "adjusting" is to create an equal pressure upon each truck. The brake was then applied upon a straight track, and the same trials as just described by me were repeated upon the same straight track and same curve as I have just mentioned, and with the same results; that is to say, with the brakes tight to sliding a pair of *of* wheels to each truck, when on the straight track, and with the brakes, when on the curve, tight and sliding all the wheels of one truck, while all the brakes were comparatively loose upon the other truck.

We then ran out on the main line of the road about four miles to Richmond Hill. We applied the brake on the east end of the car on the straight track and run the car on to the curve. The result was that on the curve the brakes on the eastern end of the car were tight; I cannot say whether the wheels were sliding or not; on the west truck the brakes were comparatively loose, that is, looser than the other ones.

We then let the brakes off and ran to Jamaica, and there applied the brake at the eastern end of the car. We ran on to the curve at Jamaica station and stopped with the brakes set. We examined and found the brakes tight on the eastern truck, and comparatively loose on the western truck.

We then let the brake off and ran out to Valley Stream, which is distant about thirteen miles from Bushwick on the main line of the road, and at which point the junction of the Rockaway Branch with the main line is made. We then set the brake upon the eastern end of the car upon the straight track and ran the car upon the curve on the western arm of the Y. We then stopped on the curve and examined the brakes. Those upon the truck nearest the windlass where the power was applied were tight, and those on the other truck were comparatively loose.

We then let the brake off and applied it on the straight track 1540 before entering upon the eastern arm of the Y and upon the same end of the car as before, and then ran on to the eastern arm of the Y. We again examined the brakes on this curve and found them tight on the end nearest the windlass where the power was applied, while the other truck was comparatively loose.

We then let the brake off and ran on to the straight track and applied the brake on the straight track, at the other end of the car, and ran on to the eastern arm of the Y again, and stopped on the curve and examined the brakes and found the brakes comparatively loose on the truck nearest the windlass where the power was applied, and comparatively loose on the other truck.

We then let the brakes off and ran on to the straight track on the main line and returned to Jamaica. We applied the brake on the straight track at the westward end of the car and ran on to the curve at Jamaica Station. We stopped on the curve and examined the brakes and found the brake comparatively loose upon the westward truck and tight upon the eastern truck.

We then let off the brake and ran to Bushwick. We then applied the brake and stopped in Bushwick yard on a straight track. We examined the brakes and found that they were out of adjustment. We then let the brake off of that end of the car and applied it at the other end of the car, and then examined the brakes and found that they were out of adjustment from that end of the car also.

We then let the brake off and put the car in the house.

Q. 9. Please state what trials were made with the car with the Tanner brake.

A. We put the Tanner brake on the car and adjusted it, and then attached an engine and ran out upon the straight track and applied the brake upon the straight track; the result was that we slid the 1541 two outer pair of wheels of both trucks, and we then let the brake off; we then started up and applied it again at the western end of the car, and ran the car on to the same curve at Bushwick that I have spoken of before, and slid all the wheels of both trucks; we then let the brake off and ran east a short distance on to a straight track, and then we started west again and applied the brake at the westward end of the car on the straight track and ran on to the same curve I have spoken of in Bushwick yard, sliding the two outer pair of wheels in each truck. We made two trials of this kind from each way, sliding all the wheels on one trial, running west, both on straight track and curve, and the outer pair of each truck running west, on the second trial, on both straight track and curve. We made the same trial running eastward, sliding all the wheels on both trucks both on straight track and curve, the brake being applied at the other end of the car. We then put the car into the house because it was late and train time. The next day of the trial with the Tanner brake we attached an engine to the car and made similar trials to those just mentioned on the straight track and curve at the Bushwick depot. We slid all the wheels of the car both on the straight track and curve.

We then started off on the road and applied the brake at the same curves, namely, Richmond Hill, Jamaica Station, and the two arms of the Y at Valley Stream, as we did at the trials of the Springfield brake above detailed by me, and made the same trials at these curves as we did with the Springfield brake. On examining the brakes at these different curves, we found the pressure of the brakes was the same on both trucks. But at the Y there was a platform which enabled us to stand and see the effect of the pressure of the brakes on the wheels of the car when it was in motion. I got out and stood on that platform and saw the car go by on these curves on the Y, and saw that all the wheels were sliding in both trucks under the application of the brakes. On returning we stopped at Jamaica, and I got out on the platform there. The car was backed down on to the straight track and the brake applied upon the straight track and run on to the curve at Jamaica Station, and we slid all the wheels of both trucks both on straight track and curve. We then run about four miles towards Bushwick from Jamaica, and stopped on a straight track. I got off the car, and the car was then backed towards Jamaica. We then run west and applied the brake and slid all the wheels of both trucks on this straight track. We let the brake off and run west a short distance, and then run east again, applying the brake from the other end of the car, sliding all the wheels on the straight track. We then let the brake off and run to Bushwick, and when we got there we applied the brake while in motion on the straight track and stopped on the straight track. I got off the car and examined the brake and found it having the same pressure on both trucks. We then ran the car into the house. 1542

Q. 10. You have stated both in regard to the Springfield brake trials and the Tanner brake trials that you examined the brakes to test their pressure upon the wheels. State whether you did this yourself; and, if so, in what way you did it?

A. I did it myself with a wooden lever six feet long, about four inches wide, and one inch and a quarter thick. The lever was applied between the brake hanger and the wheel as low down as I could get the lever in.

Q. 11. You have stated, in reference to the trials which you made with the Springfield brake, that in all the cases in which the car, with the brake applied on the straight track, passed from the straight track on to the curves and was stopped there the shoes on one truck were tight and on the other truck were comparatively loose; please state how efficient the braking was in these cases upon the truck in which the shoes were comparatively loose. 1543

A. It was very inefficient, exerting very little influence over the stopping of the car.

Q. 12. In your judgment as a railroad man state what would be the utility for continued practical use upon a railroad of a car-brake which operates as you have herein described this Springfield brake to operate.

A. I should not think it would be practicable.

Q. 13. Is there or not a difficulty in the Springfield brake in reference to its keeping up its adjustment after being originally properly adjusted?

A. There is.

Q. 14. State whether you yourself noticed the time and attention bestowed upon the adjustment of the Springfield brake on car 33 previous to the car being started out on any of the trials you have described.

A. I noticed they were taking more than ordinary pains with it.

Q. 15. When the adjustment of this Springfield brake on said car was completed for these trials previous to the starting out on the trials, how perfect was the adjustment?

A. It was as perfect as it could be done.

Q. 16. About how much of the time in the practical use of car-brakes upon railroads are they adjusted so as to be in an equally perfect condition of adjustment with said Springfield brake, as the latter was previous to starting out on these trials?

A. It is not once in a hundred times that they adjust a brake in that way.

Q. 17. What would be the effect, in reference to the economical management of a railroad, of bestowing upon the Springfield brake such attention and such length of time as you consider would be necessary to keep up its adjustment in such a manner as would be required with it if all the cars of a railroad which now have double-acting brakes were equipped with Springfield brakes? 1544

A. I think it would be very disastrous.

Q. 18. Would it or not require more men to do this adjusting than are required with the double-acting brakes at present in use?

A. It would require more men.

Q. 19. How practicable, in your judgment, would it be to keep up upon all the double-brake cars of a railroad such a condition of adjustment of the Springfield brake as would fit it to run?

A. I don't think it would be practicable.

Q. 20. State whether you observed the turn-buckles which were used upon the long rods of the Springfield brake on car 33 referred to in this deposition; and, if you did, please state whether they turned hard or easy, and whether check-nuts were needed to keep them permanently in position during the running of the car.

A. I noticed persons turning them, and saw they used a lever 2½ feet long. I thought from their motion the buckles worked hard. I should not think they required a check-nut.

Q. 21. Were these trials with the brakes which you have detailed, made under your supervision?

A. I permitted them to have the brakes put on, and I supervised the trials.

Cross-examination by M'r Whipple:

Cr. 1. I wish to repeat the twelfth direct interrogatory, substituting Tanner brake for Springfield brake; it will then read as follows: "In your judgment as a railroad man, state what would be the utility for continued practical use upon a railroad of a car-brake which operates as you have described the Tanner brake to operate."

A. It would be good.

1545 Cr. 2. Please state the names of the persons present at the aforesaid trials of both the Springfield and Tanner brakes.

A. A. P. Doane, W. Homan, F. B. Chichester, M'r S. D. Cozzens, Thomas Sayles, W'm H. Weightman. These were all present at the trial of the Springfield brake. At the trial of the Tanner brake, M'r A. P. Doane, M'r S. D. Cozzens, M'r Thomas Sayles, and W. H. Weightman were present; M'r Homan also saw the trial in the yard with the Tanner brake.

Cr. 3. Who is M'r Homan, and who is M'r F. B. Chichester?

A. M'r Homan is superintendent of the road; M'r Chichester, assistant superintendent of the road—the South Side Railroad of Long Island.

Cr. 4. From whom did you receive orders to prepare for and try these experiments in brakes?

A. M'r F. B. Carman, managing agent of the road. He gave me permission to do so, if in my judgment I thought I could do so without interfering with the business of the road.

Cr. 5. Did either the president or superintendent give any permission or direction in regard to this matter?

A. No.

Cr. 6. Who first at any time called your attention to the Springfield brake?

A. M'r Sayles.

Cr. 7. What did M'r Sayles wish of you?

A. He wished to try an experiment, and brought a letter from M'r Carman, general managing agent, as already stated.

Cr. 8. To what expense has the company been to in preparing for and carrying out these trials in brakes?

A. About two hundred dollars.

A. P. DOANE.

Sworn and subscribed before me this 27th day of November, 1872.

J. H. S. DOLMAGE,
Commissioner of Deeds.

1546 *Deposition of Walter Homan, taken at Williamsburgh, Dec. 5,* 1872.

Direct examination by M'r Cozzens:

Q. 1. What is your name, age, residence, and occupation?

A. Walter Homan; my age is fifty-three; Bayport, L. I.; my occupation is superintendent of the South Side Railroad of Long Island.

Q. 2. How long have you been superintendent of that road?

A. Since the 1st September, 1872.

Q. 3. How long have you been connected with that road, and in what capacity previous to being superintendent?

A. Since April 1, 1872. I was assistant superintendent under M'r Douglass, the superintendent, and have been connected with the road since the first tie was laid, about five years ago. Previous to April 1st, 1872, I had charge of building the depots, freight-houses, platforms, engine-houses, tank-houses, and of everything connected with the road except the roadbed, and have had entire charge of the roadbed since April 1st, 1872.

Q. 4. Were you present on the 20th day of November, 1872, at a trial of a car-brake called the "Springfield brake" on passenger-car 33 on the South Side Railroad?

A. I suppose the date is correct, though I did not take the date down, but I was present at the trial of the brake.

Q. 5. Please state in what condition were the roadbed and the rails of the South Side Railroad between the points where the trial took place on the road on the day you were present.

A. In good condition—better than what might be called "good condition." The trial was made on the best part of our road, where 1547 there is a double track. We consider where the double track is the best part of our road, the track at this part being a continuous heavy rail and fish-joints.

Q. 6. Please state whether you observed the manner in which the brake operated upon the wheels of the car at the time of this trial on the curve in the main line in the railroad yard nearest the depot building and on the curves in the main line near Richmond Hill, and at Jamaica and on the two arms of the Y at Valley Stream; and, if yea, please state what was the comparative pressure of the brake-shoes on the wheels of the two trucks when the car with the brake properly applied on the straight track passed on to these curves and was stopped on the curves?

A. I noticed it. The brake applied harder to one truck than it did to the other. When the brake was applied then on testing the brake-shoes by a lever they were found to be very tight on one truck and not so tight on the other truck. The wheels slid on the forward truck, but the wheels of the hind truck did not slide. We then reversed the application of the brake, that is, applied the brake from the other end of the car, and repeated the trial, and the same wheels that slid before, and the same wheels were not so tight on this repeated trial that were not so tight before. I mean to say that with this reversed application of the brake the result was the same as before.

Q. 7. At these trials did any person after the car was stopped try the brake-shoes with a lever; and, if so, who, and did you see the lever applied?

A. Yes; M'r A. P. Doane, the master mechanic. I saw the lever applied.

Q. 8. Would or not, in your judgment as superintendent of a railroad, a car-brake which operates as you saw the Springfield brake operate on
these trials to which you have testified be a practical brake for
1548 continued and regular use upon all the double brake cars of a
railroad?

A. It is not considered a good brake that will slide the wheels of one truck while the wheels of the other truck turn.

Q. 9. As superintendent of a railroad, would you or not, want to use a brake which operates as you saw this Springfield brake operate on said trials?

A. No, sir; I should rather not.

Cross-examination by M'r Whipple:

Cr. 1. Would you or not consider a brake a good one that would slide all the wheels of both trucks of a car?

A. No, sir; I should not consider it a good brake. I should rather have one that would not slide any of the wheels. I would rather have a brake that would apply the power to all eight of the wheels equally, without sliding. A brake may be a good brake and apply power enough to slide all the wheels of the car, but I would rather not have any of the wheels slide.

Cr. 2. Would you consider the Springfield brake a good brake if leverage enough is given to it whereby all the wheels of the car could be slid?

A. Not from the test which I saw of it.

Redirect:

Q. 10. Please state over again what you just now added to your last cross-answer, but which was not taken down?

A. I don't know what you have reference to.

Q. 11. I refer to what you said about the Springfield brake not applying the power equally to the two trucks.

A. It appears to me that I have answered that question.

1549 Q. 12. You did answer it, but the answer was not fully taken down. Please repeat all that you said in answer to the last cross-question.

A. I said that the power might be applied to those trucks so that the wheels of one truck would be sliding while the wheels of the other truck were in motion. I said that perhaps the power might be applied that would slide all the wheels, but not from an ordinary hand-brake, such as we use, I think.

Q. 13. Which brake would you consider was applying the power the most nearly equally to the two trucks of a car, a brake which would slide all the wheels of the car, or one which would slide the wheels of one truck while the wheels of the other truck revolved?

A. That which when applied would slide all of the wheels.

Q. 14. You said in your second cross-answer that a brake may be a good brake and yet slide all the wheels of a car, and you also said that you would rather have a brake that would not slide any of the wheels. Please state more fully how it is that a brake may be a good brake though it may slide all the wheels?

A. A brake to be a good brake, in my opinion, should have the power equally on all the wheels. You may put power enough on a good brake to slide all the wheels, but we don't consider in railroading that it is a good thing to slide wheels. The sliding makes "flat" wheels.

Q. 15. Is it or not a good way to show to a person—who is standing or walking beside a car upon which the brake is applied—how nearly equally the brake-shoes are pressing upon the wheels of the two trucks to apply the brake with power sufficient to slide all the wheels of the car?

A. I do not know of any other practical way; it is the only way that I have seen brakes tested. I would say that at a test at which I
1550 was present some year and one-half ago on the Flushing road—
which was a test of the "Stenard" steam brake—that that was the way that we tried the effect of the brake—by standing on the side of the track and seeing the train go by and watching the effect of the brakes.

WALTER HOMAN.

Sworn before me this 5th day of December, 1872.

J. H. S. DOLMAGE,
Commissioner of Deeds.

Deposition of Adam Kraft, taken at Williamsburgh, Dec. 5, 1872.

Q. 1. What is your name, age, residence, and occupation?

A. Adam Kraft. My age is twenty-two. I reside in Williamsburgh, N. Y., and by occupation a switchman on the Southside Railroad—in the yard at Bushwick station.

Q. 2. How long have you been on that railroad, and how long have you been switchman?

A. I have been on this road about one year and nine months. Have been switchman about four months.

Q. 3. Before you were switchman on said road what did you do there?

A. I was night watchman on that road at Bushwick depot.

Q. 4. Are you experienced in using brakes on cars, and how long have you been so?

A. I am. Have been about five months using brakes.

Q. 5. Do your duties now require you constantly to apply the brakes upon the cars running about the depot yard?

A. Yes, sir.

1551 Q. 6. Do you remember last month—November, 1872—that a brake called the Springfield brake was tried upon passenger car No. 33 of the Southside Railroad, in the yard at Bushwick, and did you pply this brake on this car?

A. I do remember, and I applied the brake on the car.

Q. 7. Do you remember a trial with this Springfield brake when the brake was applied on the straight track in the yard? And, if so, state who applied the brake at this time, and what was the effect of the brake upon the wheels of the car.

A. Yes, sir; I applied the brake at this time. When going along the straight track one pair of wheels in each truck slid, and the others did not.

Q. 8. In trying the Springfield brake, did you or not set the brake with the ratchet in the usual way when the brake was applied on the sraight track?

A. I set the brake as hard as I could, and set up the ratchet.

Q. 9. When the brake was applied on the car on the straight track and the ratchet set up as you have stated, where was the car then run and what was the effect of the brake upon the wheels of the car?

A. It was run on to the curve nearest the depot building at Bushwick. Two pair of the wheels on one truck slid and the wheels of the other truck did not.

Q. 10. Do you remember, a few days after this trial of the Springfield brake, that a brake called the Tanner brake, having a horizontal lever under the centre of the car, was tried on the same straight track in the Bushwick yard? And if you do, please state who applied the brake.

A. Yes, I applied the brake.

Q. 11. How hard did you apply the brake, and did you set up the ratchet after you had applied it?

A. As hard as it laid in my power. I set up the ratchet.

1552 Q. 12. What was the effect of this Tanner brake upon the wheels of the car after you had thus applied it on the straight track?

A. I think they worked first rate.

Q. 13. How was it as to sliding the wheels of the car on the straight track?

A. It slid all the wheels on the straight track.

Q. 14. When this Tanner brake was applied on the straight track and the ratchet set as you have stated, where was the car then run and what was the effect on the wheels?

A. It was run on to the same curve in the yard, nearest the depot building. The wheels slid on the straight track. On the curve I could not say; I was on the car.

Q. 15. Please state whether you have ever noticed the effect of the Hodge brake, which is in regular use on the passenger cars of the Southside road, as to sliding the wheels of the cars when the trains are coming into this depot at Bushwick; and, if so, state what you have noticed.

A. I have noticed, when some of these trains came into Bushwick, that all the wheels of a car were sliding when the brakes have been set up to stop the train.

Q. 16. State whether you have noticed this often or not very often.

A. Not very often.

Q. 17. On what part of the track at Bushwick have you noticed this with the Hodge brake?

A. Very nearly the middle of the yard, just striking the curve.

Q. 18. State whether you have also noticed this same effect with the Hodge brake on the same straight track and curve, nearest the Bushwick depot building, on which you saw the Springfield and Tanner brakes tried.

A. Yes, sir; I have seen the same effect.

1553 Q. 19. When you tried the Tanner brake in the Bushwick yard, how did you find that it stopped the car as compared with the Hodge brake, which is regularly used on the road?

A. I think that both of them brakes work just alike. I don't think there is any difference as to stopping the car.

Q. 20. In your daily work in the Bushwick yard do you often have to apply the Hodge brake on the cars?

A. Yes; every day.

Q. 21. Which brake, the Tanner or the Hodge, has the most slack chain to be wound up when the brake is being applied?

A. The Hodge.

his
ADAM + KRAFT.
mark.

Deposition of A. P. Doane, recalled for complainant, taken at Williamsburgh, Dec. 5, 1872.

Direct examination by M'r Cozzens:

Q. 1. When, in your judgment, is a car brake doing the most effective braking?

A. Just before the wheels slide.

Q. 2. What is the best test to the eye of a person standing or walking by the side of a car upon which a brake is applied as to whether the power of the brake is being applied equally or nearly equally to both the trucks of the car?

A. To see the wheels slide would be as good a way as any.

Q. 3. Unless the complicated and expensive test of a dynamometer be applied to the brakes, what other practical way than making the wheels slide do you know of for determining the equality of the pressure on the two trucks?

1554 A. I know of no other way except the use of the dynamometer.

Q. 4. At the trials of the Springfield and Tanner brakes to which you testified on the 27th of November, 1872, did you give any directions to the brakemen as to how they should apply the two brakes; if so, what were your directions?

A. I ordered them to set the brakes tight enough to slide the wheels, if possible. These directions applied equally to the Springfield and Tanner brakes.

Q. 5. Please state whether a car brake may be a good brake and yet be capable of applying sufficient power to slide all the wheels of a car, and please give your reason for your answer.

A. It may be a good brake, because you are sure you can reach the point just before sliding, and that point is considered desirable by railroad men.

Q. 6. Suppose a brake is found to be capable of exerting sufficient power to slide all the wheels of both trucks of a car, and suppose that it is not considered desirable to permit the wheels to be slid when it can be avoided, what would you do to such a brake?

A. I would reduce the leverage.

Q. 7. As the Tanner brake was arranged on car 33 at the time of the above-mentioned trials described by you, what, if any, difficulty would there be in preventing the brake from sliding the wheels without affecting its comparative equality of power upon the two trucks?

A. There would be no difficulty. You would have to reduce the leverage.

Q. 8. Suppose a brake operates as you, on November 27, 1872, described that the Springfield brake operated at the trials made with it, namely, the brake shoes of one truck being tight and of the other truck being comparatively loose when the car with the brake applied on a straight track passed on to the curves you spoke of, how, if at all, could
1555 you reach, or know that you had reached, the point which you say is most desirable in a brake—that is, the point where the

brake is applied to all the wheels hard enough to be just short of sliding them all?

A. Under such circumstances, you could not tell.

Q. 9. Please state whether, in your railroad experience, you have ever observed the effect as to the speed at which a train of cars moves when many of the wheels in the train are sliding, as compared with its speed when the brakes are applied short of the point of sliding; and, if yea, please state on what railroad you have seen it, what kind of cars it was, what kind of track the cars were moving on, and what the effect as to the comparative speed was.

A. I have seen trains under that condition on the railroad between Troy and Schenectady; the cars were moving on a good track, on a T rail; it was snowing; the rails were wet. I have seen that when the brakes were applied to the cars short of the point of sliding the train seemed to go slower than it did after the wheels of some of the cars came to sliding under the application of the brakes. The cars were house freight cars, and had single-acting brakes. There were about 23 cars on the train, I think, and three brakemen on the train besides the conductor, making four men in all. This train was on a heavy down grade; the train got the best of us, and we all put on the brakes as hard as we could. I was engineer on the train, and reversed the engine and failed to hold the train.

Q. 10. Will you please state whether you have ever noticed the driving-wheels of an engine slipping or sliding on the track when steam is on the engine; and, if so, what is the usual course adopted by engineers under such circumstances?

A. I have seen engines slip on the track. The usual course is to give them sand on the track, and if they continue to slip, to reverse the engine and then throw them back and let the wheels get a new hold.

1556 Q. 11. Please state whether you have ever seen the effect of the Hodge brake upon the wheels of the cars on the South Side Railroad when trains were coming in over the straight track and curves at the Bushwick depot; and, if so, please state what, if anything, you have sometimes noticed as to the sliding of the wheels at such times.

A. I have seen the cars with the Hodge brake come over the straight track and curve inquired about with the wheels sliding; at some times I have seen all the wheels of a car sliding; and sometimes not all of them; and sometimes not any of them; very seldom all of them; but I have seen them all slide a number of times under a car with the Hodge brake.

A. P. DOANE.

Sworn before me this 5th day of December, 1872,

J. H. S. DOLMAGE,
Commissioner of Deeds.

1557 JOHN CHARTS, a witness produced on behalf of the complainant, testified as follows:

Q. 1. What is your name, age, residence, and occupation?

A. My name is John Charts; I am 45 years of age; I reside in New York City, and am baggage-master on the New York and New Haven Railroad.

Q. 2. How long have you been baggage-master on said railroad?

A. About ten or twelve years.

Q. 3. Were you ever employed in any capacity upon the New York and Boston night express line, which ran over the New York and New Haven road in the years 1856 and 1857; if so, in what capacity?

A. Yes, sir; I was first brakeman on that night express.

Q. 4. For about how long a time did you act as brakeman on that train?

A. Some time in 1852 I commenced, and continued to be brakeman until I got to be baggage-master.

Q. 5. While running as brakeman, on that train, in 1856 or 1857, or thereabouts, do you remember a peculiar kind of car-break', different from the regular brake used on the New York and New Haven cars, being on the cars of said train?

A. Yes, sir.

Q. 6. Will you please state whether said brake worked well or not?

1558 A. No, sir; it did not work well.

Q. 7. What was the matter with it; how did it answer in holding the cars?

A. It wouldn't hold the cars; the blocks didn't seem to press against the wheels.

Q. 8. While you were running on that train, during the time said brake was used, do you remember any accident which happened to the train; if so, will you please state the circumstances of it?

A. Yes, sir. Coming on to New York one night from New Haven, we were nearing Stamford station, a freight-train broke in two; the signal lights and torpedoes were placed on the track to notify us, a long distance back; that night it was foggy, and the track was wet and slippery; I had the hind brake, on which was a Hodge's brake, about the time the engineer blew the alarm, and the conductor, M'r Baush, stood inside the door, and saw that I had the brake applied; the first I knew we run into three freight-cars, and we came to a stop.

Q. 9. Did you on this occasion make any effort to stop your train from running into those freight-cars by applying any of the other brakes on the train?

A. I did not. I know all the other brakes were on, as I went and looked, and found the other brakes set, after we stopped.

Q. 10. At the time these said brakes, other than the Hodge brake, were used on this night express train, at what place or places was the depot of the New York and New Haven Railroad in New York City?

A. At the corner of Canal street and Broadway.

Q. 11. After the engine was uncoupled from the train, on reaching New York, as well as when the train was started from the depot in New York, to be drawn to the engine, did you have anything to do with braking on the cars in going through the city?

1559 A. Yes, sir; more coming into the city than going out.

Q. 12. In going through the city with these brakes which have been inquired about, did you have any difficulty in holding the cars? If so, please state the nature of such difficulty.

A. Yes, sir; coming through the city to Canal street. The drivers would cut loose the horses so as not to have them run over, and I would take hold of the brake and put it on, and the car would run until we came up to some grade and stop. The driver would then hitch on again and start the car.

Q. 13. Was there or not much effect produced on the car as to holding it when you put on these brakes at these times as you have stated?

A. There didn't seem to be any on the down grades. The brakes wouldn't seem to hold any on the down grades.

Q. 14. During the time that these brakes inquired about were used on this train, was there any cars with any other kind of brake on run in the train; if so, where were such other cars put on and what kind of brakes did they have?

A. Yes; out of New York we would have three or four cars. They had the Hodge brake on. Coming from New Haven there would be one car behind—one of the New Haven cars, or sometimes one of the New Haven, Hartford, and Springfield cars.

Q. 15. Why was this one car put on to the train at New Haven?

A. To hold the train. We could not hold the train with the other brakes—the Springfield brakes. Up grade we could stop with them, going up hill.

Cross-examined by S. M. Whipple:

X Q. 16. How long were these Springfield brakes in use on the cars of this night express line?

1560 A. I couldn't tell exactly, sir.

X Q. 17. How long, according to your best recollection?

A. I think about two or three years.

X Q. 18. What brakes were in use on the cars of the night express line before and after the Springfield brake was applied and used?

A. I think the Hodge's brake.

X Q. 19. When the Hodge's brake were used on the cars of the night express line, was it customary to take on additional cars at New York to accommodate the passengers to New Haven?

A. Yes, sir.

X Q. 20. Were these cars taken off at New Haven or were they run through to Boston?

A. They might take off a car if they didn't want to use it for passengers; but if on arriving at New Haven they wanted to use the car for passengers it went on to Springfield.

X Q. 21. When the night express train arrived at New Haven for New York, has it not for a number of years been the custom to take on one or more cars at New Haven to accommodate passengers from that place to New York?

A. No, sir; that train is very light when it gets to New Haven. There has been sometimes, in case of an excursion or something of that sort, we take on some cars; but as a general thing now and always, with the exception of the time we used the Springfield brake, we leave a car or more at New Haven from that train.

X Q. 22. Did you ever leave a car from that train at New Haven when the Springfield brake was used on it?

A. Yes, sir; sometimes if two of the Hodge's brakes come on behind we would leave one.

X Q. 23. Did there ever come within your knowledge an accident on the New York and New Haven road of any kind when the Hodge brake was used?

1561 A. Yes, sir; some time at Mamaroneck we run over a horse, and it threw the trucks of the next to the last car from the track.

X Q. 24. Any other accidents within your knowledge?

A. We run over a broken rail the 29th of September, 1855.

X Q. 25. Any other?

A. No, sir; I don't remember any.

X Q. 26. On what kind of a rail does any brake hold best—a dry rail, wet rail, or frosty rail?

A. A dry rail.

X Q. 27. How much sooner in your judgment can you stop a train on a dry rail than on a wet rail or a frosty rail?

A. I couldn't answer that very correctly, but I should think a little over half way.

Redirect:

Q. 28. Under the circumstances of the accident at Stamford with the Springfield brakes, and notwithstanding the condition of the rails as you have described it, ought the train to have been stopped in time to prevent the accident if the Hodge brake had been on those cars of the train which had the Springfield brake on?

A. Yes, sir.

Q. 29. In the case of these accidents you have referred, when you ran over a broken rail and also over a horse, did the brakes have anything to do with them?

A. No, sir.

Recross:

X Q. 30. Had the Springfield brakes been in good order on that train at the time of the accident at Stamford, ought the train to have run into those detached freight cars?

1562 A. I think they were as good as ever I knew them. They were examined at New Haven and examined at Bridgeport. I knew them to be in good order that night. There were no chains broke—no nothing. The brakes were all set when I examined them.

X Q. 31. Ought the train to have run into the detached cars as you have stated had the Springfield brakes been in good order?

A. I can't tell about the order of those brakes.

X Q. 32. What brakes was in use on the cars of the Springfield, Hartford and New Haven road at the time the Springfield brake was in use on the cars of this night express line? Were they the Hodge brake or some other double brake?

A. I think it was the Tanner brake.

X Q. 33. From your experience in operating both brakes, what preference have you, if any?

A. The Hodge brake.

X Q. 34. How much better in your judgment is the Hodge brake than the Tanner brake?

A. Well, I prefer the Hodge brake for my use on a train, though the Tanner brake is a good brake.

X Q. 35. Why do you prefer the Hodge brake to the Tanner brake?

A. In the first place I have used it more, and I don't know anything else.

X Q. 36. Were you to equip the cars of a road with brakes, which would you select were it left with you to determine?

A. That would be something in this way: if they were both the same price I would take the Hodge. Both are good.

X Q. 37. Why would you take the Hodge?

A. I think it is a better brake.

X Q. 38. What brake is now in use on the passenger cars of the New Haven, Hartford and Springfield road?

1563 A. On our road, I think the Hodge brake.

X Q. 39. Were it put upon you to stop a train in the quickest possible time by means of hand-brakes, which brake would you choose for this purpose, the Hodge or Tanner?

A. The Hodge.

X Q. 40. Why choose the Hodge?

A. Because I am more used to it, and I think it is the best brake.

X Q. 41. Were it put upon you to stop a train in the quickest possible time, and you were given brakemen who had operated other than the Hodge and Tanner brakes, and well understood applying brakes, which brake would you choose?

A. I might choose the Hodge brake.

X Q. 42. You will please give your reason for such choice.

A. I think it is the best brake.

X Q. 43. Do you mean by that it is the best brake for any one to operate?

A. It would be the best for me. I believe it would be the best for any one.

X Q. 44. Why would it be the best brake for any one?

A. Because I think it is the best in use, at least the best I have ever used. There may be other brakes that I don't know anything about.

X Q. 45. Why is the Hodge brake the best brake you have ever used?

A. Because I think it binds on the wheels more and better than any other.

Redirect:

Q. 46. You said in your recross answer, speaking of the Spring-
1564 field brakes at the time of the Stamford accident: "I can't tell about the order of those brakes." Please explain more fully what you mean by this?

A. Because, in the first place, if they were out of order I couldn't go to work and put them on. I couldn't make them any better than they were on that occasion. The brakes would not hold the train. I never knew them to; what I mean is if the brakes were not in order on that occasion I couldn't make them any better.

Q. 47. You said in your 17th cross answer that you thought the Springfield brakes were on that train two or three years. May it not be that they were on only about a year or so?

(Objected to as seeming to instruct the witness.)

A. I think it was about two or three years.

Q. 48. Have you any special circumstances to fix the length of time by?

A. No, sir. We used them running into Canal street and also 27th street depot.

Q. 49. Are you a mechanic, and do you understand constructing and adjusting of brakes to obtain the greatest service from them?

A. No, sir. All I know is if I take hold of a brake whether it's in good working order.

Q. 50. During the time the Springfield brake was used, do you know of an instance when that brake was in working order?

A. I never found it to be when I used it.

Q. 51. Had the old single brake been applied to all the cars of that train at the time of the Stamford accident, with the help of the Hodge brake on one car, could the train have been stopped in time to prevent the accident, the number of brakemen being the same in both cases?

A. I have never used the single brake on that road.

1565 Q. 52. It being understood that the single brake applies the power of the brakemen to one truck while the double brake applies the same power to both trucks, could that train, in your judgment, have been stopped before running into those detached freight cars with the same number of brakemen, and the aid of the Hodge double brake on the rear car?

A. Yes, sir; if the single brakes held any. I think I could have stopped that train with the Hodge brake alone on the hind car, if the freight cars had been eight or ten car lengths further off. I had no other brake to rely on in the whole train. We couldn't depend on any other brake on that train but the Hodge brake. We couldn't depend on the Springfield brakes.

Q. 53. Had there been an application of the single brake to all the other cars of that train but the one that had the Hodge brake on, and one-half of these single brakes had been applied with the Hodge brake, do you think the accident could have been prevented?

A. I think so, if the single brakes held any.

Recross:

X Q. 54. Will not a single break', so far as it goes, hold just as well as the half of the double brake?

A. I am not prepared to answer this. I have never used the single brake.

X Q. 55. What is the double brake but the union of two single brakes, and the operating of the same together?

A. They ought to be just the same, if they were both equally good.

JOHN CHARTS.

Subscribed and sworn to before me this 8th day of October, 1872.

T. B. BEECHER,
Notary Public N. Y. County.

1566 **ISAAC L. WADLEIGH**, a witness produced on behalf of the complainant, testified as follows:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Isaac L. Wadleigh. My age is 51 years. My residence is New York City, and am at present engaged in letting room and steam-power at 317 East 22nd st., New York City.

Q. 2. Were you ever engaged as locomotive engineer *no* any railroads; if so, on what railroads?

A. Yes, sir; on the Stonington Railroad, and Western Railroad of Massachusetts.

Q. 3. About how long were you locomotive engineer on the Western Railroad, and what kind of trains did you run on that road?

A. A little over seventeen years. I run all kinds of trains that were run on the road.

Q. 4. During any part of the seventeen years, did you run on either of the New York and Boston express lines?

A. Yes, sir; both the night and day express.

Q. 5. For about how long did you run on these express lines, and between what points did you run?

A. I run on the night express-train 25 months, when it was first put on. I run the day express-train 14 years, 1 month, and 18 days. I run both those trains from Worcester to Springfield and return.

Q. 6. Do you remember, while you were running this day express-train, that a brake called the Springfield brake was put upon the cars of that train?

A. Yes, sir.

Q. 7. How well did these Springfield brakes answer for holding the cars of that train?

A. Well, they didn't answer very well.

Q. 8. What was the difficulty with them ?

A. They were a very poor thing, any way. The difficulty with 1567 the brakes was that you couldn't rely on them to stop the train either at a regular stopping place or where some unfor'seen thing occurred and you wished to stop the train. They were not to be relied on.

Q. 9. While these Springfield brakes were used on your train, do you remember any accident happening when the engine ran off the track ? If you do, please state the circumstances fully.

A. Yes, sir; when I was running east and came in sight of Brimfield turnout I saw a switch wrong, and I blew to brake, and tried to stop, but couldn't until we ran off the other end of the turnout into the bank.

Q. 10. To what cause was your inability to stop before running off due ?

A. We hadn't any brakes on the train that you could call brakes only the one on the tender, although they had the name of brakes.

Q. 11. To what brakes do you refer "that couldn't be called brakes" ?

A. What is called the Springfield brake.

Q. 12. When the Springfield brakes were used on your train, how well were you able to stop at stations, as a general thing ?

A. Well, we wasn't able to stop, as a general thing, well at all. We stopped as soon as we could. I used to give according to the place. If we wanted to stop at West Brookfield going west, I used to give them about three times the distance that I did when we had proper brakes on the train; also, at Palmer; then, sometimes we run by.

Q. 13. You say "give them about three times the distance." What do you mean by "give them" ?

A. Why, to shut off steam and give the brakesman distance to stop in.

Q. 14. What kind of brakes were used on the cars of said day-express train before these Springfield brakes were put on ?

A. The Hodge brakes.

1568 Q. 15. While the Hodge brake was used on that train, how well were you able to stop at stations, as a general thing ?

A. Well; very well.

Q. 16. While you ran on said day-express, were there any cars run in the train belonging to the Western Railroad which had on single brakes ?

A. Yes, sir.

Q. 17. Please state which brakes held the trains best, the Springfield brakes or these single brakes ?

A. The single brake. You could rely on the single brake for what it would do. The others were kept in as good order as you could keep them, but they wouldn't apply.

Cross-q. 18. For what purpose were cars of the Western road, with the single brake thereon, attached to the express-train run by you ?

A. To carry passengers.

Q. 19. Was the brake on the tender of your engine, which hauled the express-train, a good brake ?

A. Yes, sir.

ISAAC L. WADLEIGH.

Subscribed and sworn to before me this 8th day of October, 1872.

T. B. BEECHER,
Notary Public N. Y. County.

1569 FURTHER REBUTTING TESTIMONY ON BEHALF OF COMPLAINANT.

Testimony taken at New York, commencing April 25th, 1873.

ALBERT BRIDGES recalled by complainant.

Q. 1. Are you the inventor and patentee of what is called the swing bolster of railroad-cars?

A. 1. I am one of the inventors and patentees. It was invented and patented by Davenport & Bridges in 1841.

Q. 2. What was the object of this invention?

A. 2. To prevent the lateral shocks of the car-body by the concussion of the wheels against the rails.

Q. 3. How much longitudinal motion did you allow the swing-beam between the two truck-timbers between which it moved?

A. 3. Not any. The swinging bolster was allowed to play laterally between two cross-sills, with a friction sufficiently tight to prevent sudden lateral motion by the swinging of the pendulous links; should there
be space allowed for the bolster to swing *two* freely the lateral mo-
1570 tion would be felt more than it would be if retarded by the fric-
tion; therefore, it should have no longitudinal play.

Q. 4. Is or is not this swing-beam in general use on railroads?

A. 4. It is in general use on the railroads of the United States.

Q. 5. Are you acquainted with what is called the Tanner patent for double-acting car-brakes?

A. 5. I am.

Q. 6. Please state from your experience as a practical car-builder what effect longitudinal motion of the swing-beam would have upon the practical working of the Tanner brake?

A. 6. It would have no effect on the practical working of the brake, in my opinion, as the brakes draw the trucks towards the centre lever.

ALBERT BRIDGES.

Deposition of W'm H. Weightman, recalled for complainants, taken at New York, May 1st, 1873.

Direct examination:

1. Int. Have you recently made a diagram showing the operation of the Springfield brake, on a railroad car, on different curves, If so, please file the same marked "Weightman's diagram."

A. I have, and herein file the same as part of my answer. It is drawn to a scale of half an inch to the foot. The extreme length of the body represented in this diagram is 50 feet. The different radii represented are 800 feet, 500, 400, 300, 200, and 100 feet, and one of the drawings represents a car upon a straight track.

1571 2. Int. What is the length of the short chain between the windlass shaft and truck-lever; also, of the long rod and chain between said windlass and the truck-lever of the other truck?

A. The short chain is 3 feet 8½ inches; long rod and chain, 34 feet 10 inches on straight track.

3. Int. Can you by means of diagram fully illustrate what the effect would be of using said Springfield brake on a car running from a straight track on to curves of different radii, as represented in the diagram?

A. According to the diagram, a car in passing from a straight track on to curve of a different radii would have (the brakes being applied on a straight track) the effect of lengthening the short chains, and shortening the long rods and chains, or vice versa, shortening the short chains, and lengthening the long rods and chains, as by diagrams, with the brakes applied at the windlass, on the inside of curves, the differences are, on short chains, as follows, viz:

For	800	ft.	radius	track,	½	an inch	longer.
"	500	"	"	"	1⅛	inches	"
"	400	"	"	"	1¾	"	"
"	300	"	"	"	2	"	"
"	200	"	"	"	3	"	"
"	100	"	"	"	6	"	"

And on long rods and chains as follows, viz:

For	500	ft.	radius	track,	⅛	of	an	inch	shorter.
"	400	"	"	"	¼	"		"	"
"	300	"	"	"	½	"		"	"
"	200	"	"	"	1¼	"		"	"
"	100	"	"	"	1⅝	"		"	"

4. Int. What would be the effect of these variations on short and long chains and rods, the brakes being applied on a straight track, and the car then run on to a curve?

1572 A. It would tighten the brakes on one truck, while it loosened them on the other.

W. H. WEIGHTMAN.

New York, *May 1st*, 1873.

Louis E. Rood, a witness produced on the part of the complainant, and being duly cautioned and sworn, testifies as follows:

Int. 1. What is your name, age, residence, and occupation?

A. Louis E. Rood; I am 59 years old; reside in New York City; and am a car inspector on the New York, New Haven & Hartford Railroad at the passenger station in New York City.

Int. 2. How long have you been car inspector?

A. For the last twenty years, for the New York and New Haven Railroad Co. in New York City, now the New York, New Haven and Hartford Railway Company.

Int. 3. Do you remember of a certain car-brake called the Springfield brake being put on the New York & Boston express line cars about the year 1857?

A. Yes; I do.

Int. 4. Who had to attend to the adjusting of those Springfield brakes on said line cars when they were here in New York City?

A. I had charge of them.

Int. 5. Please state, if you know, how those Springfield brakes worked; state fully.

A. Those brakes never worked properly, they gave me a great deal of trouble to keep them adjusted; they would oftentimes, in going into the yard at 27th street, bind on the curve so that we would have to let out the connecting-rods between the brake beams to allow the car
1573 to go round the curve; sometimes when the cars were under considerable headway they would go round the curve into the yard without letting out the connecting-rods; we were obliged to take a great deal of pains in adjusting them in the yard, and they required such nice adjustment on account of their not being in any way self-adjustable that many of the men under me were unable to adjust them, and I was obliged to assist in their adjustment myself, as a general

thing. Every time the cars came into the yard we had to adjust these brakes, so as to be able to hold the cars in switching them, to make up the trains, and this adjustment was such as to allow them to operate when on a straight track, so that in order to take the car round the curve, on leaving the yard, we had to give the nuts on the connecting-rods a certain number of turns back to loosen the brakes, and when we got the car round the curve, and out on the straight track, we had to give the nuts the same number of turns up again, so as to leave the brakes adjusted when the train started for Boston. We had to follow the trains up from the yard to 32nd street, where the cars were hitched together, and the locomotive attached, in order to get the nuts screwed up. The cars stopped some little time at 32nd street, and this gave us sufficient time to screw the nuts up.

Int. 6. What brakes were used on said line cars before and after these Springfield brakes?

A. The Hodge brake.

Int. 7. How many men did you have to assist you in adjusting these Springfield brakes?

A. Two regular men, and oftentimes I had to call in others to assist us.

Int. 8. Did you or not hear any complaints made about the working of the Springfield brakes; and, if so, from whom, and what was the nature of such complaints?

A. I did; the train brakemen generally complained that they could not hold their train; this complaint was very often made.

1574 Int. 9. About how close to the wheels were the brake shoes of these Springfield brakes, after you had adjusted them, when the train was ready to start for Boston?

A. We adjusted them as close as we could, and not have the shoes bear on the wheels while the cars were in motion.

Int. 10. Did you or not consider this Springfield brake a safe brake for a passenger train of cars?

A. I did not, for the reason that it was so very liable to get out of adjustment, and even when adjusted in the very best manner, it would not work well. M'r Hoyt, the superintendent of the New York and New Haven Railroad, often came to me while those Springfield brakes were on the cars, and asked me if I could not fix the brakes so they would work. I told him I was doing the very best I could with them. He said there were a great many complaints about their working badly.

Int. 11. How does the expense of keeping these Springfield brakes in repair compare with that of other brakes you have had to do with?

A. The expense would be very much greater than any other brake I have had to do with, and would be so great that I do not think any railroad company could afford to use them.

LOUIS E. ROOD.

Sworn to before me this 1st day of May, 1873.

WESLEY GLEASON,
Notary Public, N. Y. County.

1575 *Corrections by Emery Stebbins and Edward Lang, witnesses for defendants, of portions of their testimony given for defendants.*

BOSTON, *April 26, 1873.*

M'r Emery Stebbins, a witness on the part of the def'ts, called upon the reporter, M'r Yerrinton, and said that he wished to make a correction of his testimony, given on the 21st of April, 1873, in respect to the model about which he was questioned at that time, marked "Def't's Exhibit, Springfield Brake No. 3." He stated that inasmuch as he had said in that answer that that model correctly represented the Springfield brake used upon the New York and Boston line cars in 1857, he now wished to say that the truck levers in the actual line cars may have been a little nearer the ends of the trucks than shown in that model; but that that would not make any difference in the working of the brake.

By M'r Cozzens:

X-int. 2. You also testified the other day that when the New York and Boston line cars, having the Springfield brake upon them, 1576 reached Springfield, where you were at that time stationed as car-inspector, you, during the first part of the time that that brake was used on those cars, adjusted the brakes there?

A. I did; yes, sir, more or less.

X-int. 3. Did you, after this, when you found that the brakes were too loose take up the slack in them?

A. Yes, sir, some of them; when we found they were so loose they would not operate well we took them up.

X-int. 4. This sort of thing you did as long as the brake continued in use?

A. Yes, sir.

EMERY STEBBINS.

APRIL 26, 1873.

M'r Edward Lang appeared and stated that he would like to be more correctly understood in reference to the testimony given by him in this case, on behalf of the def'ts, on the 19th of April, 1873, in respect to the complaints made by G. F. Lincoln and H. M. Rogers about the Springfield brake; that he now observes that the question put to him the other day was whether complaints had been made to him "before" the men referred to went to Springfield to testify; that he did not, in answering the question, notice about the word "before," or whether it was before or after, and for that reason made the answer that he did at that time, namely, "Not that I remember in particular." But that the correct statement of the fact is as he gave it in his testimony in answer to interrogatory 13, on page 373 of the complainant's accounting record.

EDWARD LANG.

1577 TESTIMONY ON BEHALF OF THE COMPLAINANT, TAKEN AT BOSTON AND PROVIDENCE.

Deposition of William R. Hutchings, taken at Boston April 26, 1873.

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. William R. Hutchins; age, 53; residence, Boston; occupation, car-inspector on the Boston & Albany Railroad.

Int. 2. About how many years have you been car-inspector on that railroad?

A. Twenty years; that is, the Boston & Worcester and Boston & Albany.

Int. 3. During those twenty years where have you been stationed as such car-inspector?

A. At Boston.

Int. 4. Do you remember that about the year 1857 a brake called the Springfield was put upon the cars of what was called the New York & Boston express line.

1578 A. Well, I recollect a brake, but I can't say as I really understood it by that name; there was a brake put on there, and from what I have learned about it since, to the best of my judgment, that is what it was called, the Springfield brake.

Int. 5. As car-inspector at Boston during the period that this Springfield brake was used on these line cars, was it within your duty to look over the cars and adjust said brakes?

A. Yes, sir, it was.

Int. 6. About how often, while the Springfield brakes were on those line cars, did you adjust them at Boston?

A. Every day, to a greater or less degree; sometimes more, sometimes less; some of them wanted a great deal of work, and some of them didn't want so much.

Int. 7. I suppose you did all that was necessary?

A. All that was necessary.

Int. 8. In so adjusting these Springfield brakes, how tight did you make the chains?

A. Well, it was ruleable to have the slack about all taken up on the chain; that would consequently fetch the brake-shoes quite near to the wheels in having the slack of the chains taken up.

Int. 9. And that was the way you did it, was it?

A. Yes, sir.

Int. 10. In so adjusting those brakes at Boston, how hard did you try to make them work well?

A. Well, I tried very hard sometimes, very hard; it was pretty hard work to keep them in order.

Int. 11. On the whole, taking one time with another, how hard did you try to make them work well?

A. Well, I should say, to answer the question, it was hard work all the time; I did the best I could to make the brakes effective and do the most good, and work as well as they would.

Int. 12. Did the best you could all the time?

1579 A. Yes, sir; all the time.

Int. 13. About how long did it usually take you to adjust those Springfield brakes on one train?

A. Well, there were two men of us at work; we generally worked together, and it took us on an average about two hours every day to adjust the brakes on one train; one train was at Boston one day, and was adjusted, and the counterpart train was in Boston the next day, and was adjusted.

Int. 14. How many of these line cars, on an average, were there in each one of those trains?

A. There were two sitting up cars, a smoker, baggage-cars, and mail-car, five in all.

Int. 15. Please state whether you heard complaints from the brakemen on the train about the working of those Springfield brakes.

A. I have, at different times; the men would come and say, "Hutchins, can't you adjust these brakes?" not speaking in just that way: "Can't you fix these brakes to make them work, so that they will hold the train? We can't do anything with those brakes at all." My reply was that I would do the best I could.

Int. 16. Well, about how often did these complaints come to you, as near as you can tell?

A. Well, I should think it was about every day.

W'M R. HUTCHINS.

(No cross examination.)

1580 *Deposition of John Copithorn, taken at Boston April 26, 1873.*

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. John Copithorn; age, 25; residence, Somerville; occupation, car-builder.

Int. 2. By what railroad company are you employed?

A. Boston, Lowell and Nashue.

Int. 3. How long have you been in the employ of that company?

A. Well, I have been in their employ about eight years; during that time I have left twice; I have been off about a year out of the eight.

Int. 4. At what place do you do your work for said company?

A. I work in the car shop at East Cambridge.

Int. 5. Do you remember that, sometime last year, brakes called the Springfield brakes were put up on some of the cars of the Boston and Lowell R. R.?

A. Yes.

Int. 6. State who did the work of putting those brakes on to those cars.

A. It was myself and a man named John Hillock put them on.

Int. 7. How many cars, on that road, had those brakes on them?

A. There were four, I believe; three passenger-cars and a baggage-car.

Int. 8. Did you have anything to do with adjusting those Springfield brakes, and keeping them in order while they were on those cars?

A. I did.

Int. 9. During the time that you took part in adjusting those
1581 brakes, and keeping them in order, did any other man work with
you, and if so, who was it?

A. A man by the name of John Hillock worked with me, mostly; a man by the name of McAllister worked part of the time.

Int. 10. Do you remember that, while those Springfield brakes were on that train, there was a trial or test of them made on the road during about a week?

A. Well, there was a trial made.

Int. 11. During this time, did you work at adjusting and taking care of the Springfield brake on these cars?

A. I did.

Int. 12. Please state how you went to work to adjust the brakes on those cars at this time.

A. We used to put a piece of wood, about 3-8 of an inch thick, between each brake-shoe and the wheel, and tighten the connecting-rods until the brake-shoes came up to the wood. After we had done that, we screwed up the swivels on the long brake-rods, & tightened them up until we had taken up all the slack of the chain on the long rod and the short rod, to'. We then took the pieces of wood out from between the brake-shoes and the wheels.

Int. 13. Please state whether you had any trouble in making these adjustments of those brakes; and if so, in what respect did you have trouble?

A. We had trouble in getting them both alike on both ends. We

Int. 4. Do you remember that about the year 1857 a brake called the Springfield was put upon the cars of what was called the New York & Boston express line.

1578 A. Well, I recollect a brake, but I can't say as I really understood it by that name; there was a brake put on there, and from what I have learned about it since, to the best of my judgment, that is what it was called, the Springfield brake.

Int. 5. As car-inspector at Boston during the period that this Springfield brake was used on these line cars, was it within your duty to look over the cars and adjust said brakes?

A. Yes, sir, it was.

Int. 6. About how often, while the Springfield brakes were on those line cars, did you adjust them at Boston?

A. Every day, to a greater or less degree; sometimes more, sometimes less; some of them wanted a great deal of work, and some of them didn't want so much.

Int. 7. I suppose you did all that was necessary?

A. All that was necessary.

Int. 8. In so adjusting these Springfield brakes, how tight did you make the chains?

A. Well, it was ruleable to have the slack about all taken up on the chain; that would consequently fetch the brake-shoes quite near to the wheels in having the slack of the chains taken up.

Int. 9. And that was the way you did it, was it?

A. Yes, sir.

Int. 10. In so adjusting those brakes at Boston, how hard did you try to make them work well?

A. Well, I tried very hard sometimes, very hard; it was pretty hard work to keep them in order.

Int. 11. On the whole, taking one time with another, how hard did you try to make them work well?

A. Well, I should say, to answer the question, it was hard work all the time; I did the best I could to make the brakes effective and do the most good, and work as well as they would.

Int. 12. Did the best you could all the time?

1579 A. Yes, sir; all the time.

Int. 13. About how long did it usually take you to adjust those Springfield brakes on one train?

A. Well, there were two men of us at work; we generally worked together, and it took us on an average about two hours every day to adjust the brakes on one train; one train was at Boston one day, and was adjusted, and the counterpart train was in Boston the next day, and was adjusted.

Int. 14. How many of these line cars, on an average, were there in each one of those trains?

A. There were two sitting up cars, a smoker, baggage-cars, and mail-car, five in all.

Int. 15. Please state whether you heard complaints from the brakemen on the train about the working of those Springfield brakes.

A. I have, at different times; the men would come and say, "Hutchins, can't you adjust these brakes?" not speaking in just that way: "Can't you fix these brakes to make them work, so that they will hold the train? We can't do anything with those brakes at all." My reply was that I would do the best I could.

Int. 16. Well, about how often did these complaints come to you, as near as you can tell?

A. Well, I should think it was about every day.

W'M R. HUTCHINS.

(No cross examination.)

1580 *Deposition of John Copithorn, taken at Boston April 26, 1873.*

Direct examination by M'r Cozzens:

Int. 1. What is your name, age, residence, and occupation?

A. John Copithorn; age, 25; residence, Somerville; occupation, car-builder.

Int. 2. By what railroad company are you employed?

A. Boston, Lowell and Nashue.

Int. 3. How long have you been in the employ of that company?

A. Well, I have been in their employ about eight years; during that time I have left twice; I have been off about a year out of the eight.

Int. 4. At what place do you do your work for said company?

A. I work in the car shop at East Cambridge.

Int. 5. Do you remember that, sometime last year, brakes called the Springfield brakes were put up on some of the cars of the Boston and Lowell R. R.?

A. Yes.

Int. 6. State who did the work of putting those brakes on to those cars.

A. It was myself and a man named John Hillock put them on.

Int. 7. How many cars, on that road, had those brakes on them?

A. There were four, I believe; three passenger-cars and a baggage-car.

Int. 8. Did you have anything to do with adjusting those Springfield brakes, and keeping them in order while they were on those cars?

A. I did.

1581 Int. 9. During the time that you took part in adjusting those brakes, and keeping them in order, did any other man work with you, and if so, who was it?

A. A man by the name of John Hillock worked with me, mostly; a man by the name of McAllister worked part of the time.

Int. 10. Do you remember that, while those Springfield brakes were on that train, there was a trial or test of them made on the road during about a week?

A. Well, there was a trial made.

Int. 11. During this time, did you work at adjusting and taking care of the Springfield brake on these cars?

A. I did.

Int. 12. Please state how you went to work to adjust the brakes on those cars at this time.

A. We used to put a piece of wood, about 3-8 of an inch thick, between each brake-shoe and the wheel, and tighten the connecting-rods until the brake-shoes came up to the wood. After we had done that, we screwed up the swivels on the long brake-rods, & tightened them up until we had taken up all the slack of the chain on the long rod and the short rod, to'. We then took the pieces of wood out from between the brake-shoes and the wheels.

Int. 13. Please state whether you had any trouble in making these adjustments of those brakes; and if so, in what respect did you have trouble?

A. We had trouble in getting them both alike on both ends. We

could not get the brake-shoes so that they would bear on the wheels of each truck alike.

Int. 14. During this time, about how long did it take you to adjust the Springfield brakes on those four cars?

A. It took us about an hour from the time we went at them to do it; every time we had to adjust them, whether it was every day or every two days, every time we had to adjust them it took about an hour to do it, all the time we had, anyway.

1582 **Int. 15. About how much time did you have to adjust them in?**

A. About an hour; the train stood there an hour and ten minutes, but it took us about five or ten minutes to get our tools and get up to the car-house; it was just about an hour.

Int. 16. State whether you were able to get the adjustment finished within this hour?

A. No, we were not, always.

Int. 17. While those Springfield brakes were on those cars, did you hear any complaints from the brakemen about how they worked?

A. I did.

Int. 18. About how often did you hear such complaints?

A. Every day we would go to adjust them.

Int. 19. What were the complaints?

A. They would swear and say they could not make them work; could not make them hold; they would run by stations; they could not see why it was. And they would try to blame us fellows; say we did not adjust them right; they could not make time with them they said.

Int. 20. While you took part in adjusting those brakes, how hard did you try to adjust the brakes?

A. I tried as hard as I could; worked every way and tried to make them work; tried almost every way.

Int. 21. How difficult do you consider it to be to adjust those Springfield brakes so that they will work?

A. I call it pretty difficult. I couldn't adjust them so that they would work on all the wheels alike, and I don't believe any other man can get them so that they will work just right.

Int. 22. Did M'r Benjamin C. Read ever give you any instruction about what to do to adjust those brakes?

A. Yes, sir; he used to give us directions about the work all
1583 **the time; he would tell us what to do to them; and we would do**
as he said.

Int. 23. State whether or not M'r McAllister, of whom you have spoken, was competent to carry out the instructions received from M'r Read about how to adjust those Springfield brakes.

A. He was.

Int. 24. Do you know M'r S. M. Whipple?

A. I do.

Int. 25. You have said that you and Hillock put those Springfield brakes on to those cars; in putting them on, did you go by anybody's instructions, and, if so, by whose?

A. We went by M'r Read's and M'r Whipple's instructions.

Int. 26. State whether M'r Whipple was present at any time when you were adjusting those Springfield brakes.

A. He was.

Int. 27. About how often was he so present?

A. He was there a number of times.

Int. 28. At any time when M'r Whipple was present at the adjust-

ment of the brakes, did he take any part in adjusting them; if so, what did he do?

A. He did; he tightened the swivels on the long rods; he stood right there near us, and sometimes he would give them a turn, and sometimes he would tell us how to tighten them; I don't mean to say he did it all the time himself.

Int. 29. About how often did he do this?

A. Several times; I can't state how many; he and M'r Read would be there with us some of the time; M'r Read would come every time and tell us what to do, and then go off.

JOHN COPITHORN.

(No cross-examination.)

1584 *Deposition of Olney L. Smith, recalled for complainant, taken at Boston April 29, 1873.*

Int. 1. Please state whether you were present at certain experiments with the Springfield and Tanner brakes on the Providence and Worcester Railroad on the 28th and 29th of March, 1873, at which also were present M'r S. M. Whipple and M'r Alfred Berney.

A. Yes; I was present.

Int. 2. Please state whether on the first of these two days, when the experiment with the Tanner brake was made, you experienced any difficulty in ascertaining the indications of the scales, and, if so, what difficulty.

A. We did experience difficulty, owing to the high speed at which the engineer drew us.

Int. 3. Please state at what speed the engine drew you during the experiments with the Tanner brake.

A. The first part of the time, in going away from Providence, as near as I could judge from the movements of the car, the engine was drawing us at about twenty miles an hour.

Int. 4. Please state how well you were able, at this speed, to take indications from the scales.

A. I could not take indications at that speed, because the movements of the index of the scales were so rapid that it would be impossible to determine at what figures it was pointing; the index seemed to go almost as quick as lightning at that speed.

Int. 5. Finding this to be the case at this speed of twenty miles an hour, what did you do?

A. We got the speed down to about ten to twelve miles an hour.

Int. 6. After reducing the speed to ten to twelve miles an hour, did you run through the "Ledge curve," so called?

A. Yes; we did.

1585 Int. 7. When taking the indications from the scales, where were you, and what did you do?

A. I sat right over the scales at the south end of the car.

Int. 8. What did you do?

A. I took all the indications at my end of the car while passing through the curves.

Int. 9. Please state how you took the indications.

A. I took the number of points stated on the scale at the extremes each way of the movements of the index; as, for instance, if the index moved between, say, 24 and 28 pounds, I would take the 24 and the 28, but pay no attention to the intermediate pounds in between.

Int. 10. While you were doing this, where was M'r Berney?

A. He was at the scale at the north end of the car.

Int. 11. Please state what was the amount of variation with the Tanner brake at your end of the car in going through the "Ledge curve."

A. The brake was set at twenty-eight pounds on the straight track before entering the curve, and it varied from 28 to 40 pounds on the curve.

Int. 12. Please state about what portion of an inch the index would have to move to indicate two pounds.

A. A very small portion of an inch.

Int. 13. Please state whether you tried the Tanner brake in this experiment on the curve known as "Eaton's curve."

A. Yes; we tried it on that curve.

Int. 14. Please state what variation the scale showed on that curve.

A. The brake was set on the straight track before entering the curve at twenty-eight pounds; the car standing still on the straight track; as the car went on through the curve the scales varied from 28 to 32 pounds.

1586 Int. 15. Did you also in this Tanner experiment run through the Paint-shop curve?

A. We did.

Int. 16. Please state how you took the indications from the scale while running through said curve.

A. I took the two extreme points; that is, when the index-figure went one way I waited until it stopped its movement in that direction and then took the number of pounds at the extreme of its movements in that direction, and when it went in the other direction I waited until it stopped that way and took the number of pounds at the extreme of its movements that way; the variation made on my end of the car was from 6 to 18 pounds.

Int. 17. In trying the Tanner experiment on the Paint-shop curve, did the car stop on any part of the curve?

A. No; it did not stop at all; it did not stop until it reached the straight track at the other end of the curve.

Int. 18. Please state how much a person at the other end of the car could tell about what your scale showed, on going through this curve, at the instant that the scale at such other end showed any given number, as, for instance, either six or thirty pounds.

A. He could not tell anything about it; it would be impossible for him to see my scale unless he walked right up to it.

Int. 19. After he left his scale when it indicated a certain number of pounds and walked over to see your scale, please state how he could tell what changes were taking place in his scale while he was walking over to yours and back again, the car being in motion through a curve.

A. He could not see what his scale indicated while he was walking to and returning from my scale, so that it would be impossible for him to tell what variations his scale was showing while he was looking at mine.

1587 Int. 20. Please state whether on the next day of these experiments, when the Springfield brake was tried, you heard any conversation on the subject of the indications which the scales were giving for the Springfield brake between M'r Whipple and M'r Berney, and, if so, please state what you heard.

A. At the first application of the Springfield brake, as we were going up under the bridge, just out of the yard in Providence, where there is a curve, the scales indicated a very large variation between the two trucks. I heard M'r Berney say to M'r Whipple, "you must make a better show than this—this won't do, Whipple." M'r Berney and M'r Whipple traveled back and forth between the two scales and I heard M'r Berney make that remark, and M'r Whipple then got down underneath the car and adjusted the rods; I heard him adjusting the brake-rods.

Int. 21. Please state whether you came to Boston last Saturday afternoon, April 19, 1873; and if so, for what purpose?

A. I did. I was requested to come by M'r Whipple, to give my testimony in the case about these trials.

Int. 22. Upon reaching Boston that day, did you have an interview with M'r Whipple? and if so, please state what the interview was.

A. I met M'r Whipple and he asked me to step into a room with him. He said he wanted to fix matters. We went into the room and closed the door, and sat down to a small table. He wanted to compare M'r Berney's notes with mine. I showed him mine. He said there was too much variation between my notes about the Springfield brake and M'r Berney's. I inquired of him what alteration he wanted to make. He said he wanted to change 32 pounds to 24 pounds in my notes to correspond with M'r Berney's figures, and then have me swear to it. He said he wanted me to corroborate M'r Berney. I told him that he
1588 couldn't do it, that I sat to the scales by his request, and he told me he should call upon me to swear to the notes I took; and I told him that I paid particular attention and I was sure that my notes were correct and I could not allow him or any one to change them. He said that he couldn't put me on the stand unless we could change my notes to correspond with M'r Berney's, as it would be of no benefit or use to him; it would knock or spoil the experiment. He said that he was sure that our scales both set on the start at twenty-four pounds. I asked him to put me on the stand and let me swear to the notes I had, and he said he couldn't do it as it showed to' much variation.

Int. 23. Please state whether the cast-iron wheels which are used for car-wheels are even or true, or perfectly round on their circumferences.

A. They are not, and there is no wheel round unless it is turned free from uneven places.

Int. 24. Please state what effect this lack of roundness and these inequalities of surface will have upon the brake-shoes, and hence upon the indications given by scales as they were tried in the above-mentioned experiments.

A. It would have the effect of shaking the scales very much, as the higher and lower places on the wheels respectively came round against the brake-shoes, they would cause the scales to vary from two to six pounds at least, no matter what speed we were going, whether high or low.

Int. 25. Please state what in your judgment would be the effect in the use of the Tanner brake as to the equality of the action of the brake upon the two trucks of a car when the car with the brake applied passes from a straight track on to a curve, provided the line of draft from the centre lever to the tops of the truck-levers be substantially in a line with the king-bolts of the car.

A. It would equalise the power between the trucks.

1589 Int. 26. What in your judgment would have been the effect in the experiment with the Tanner brake above testified to, in going over the curves, had the truck-levers in the car been so arranged that the line of draught from the centre-lever to the tops of said truck-levers would have been substantially in a line with the king-bolts?

A. I think there would have been but little if any variation between the two trucks.

Int. 27. As you have seen the Springfield brake recently in use upon one car upon the Providence and Worcester Railroad, placed there by M'r Whipple, or at M'r Whipple's request, please state what would be the difficulty in keeping a brake of that character in proper adjustment.

A. I should say the difficulty would be great to keep those brakes properly adjusted so as to make good stops, and we shouldn't use the brake if we could get any other. It requires too nice an adjustment to make it a practical brake.

Int. 28. Please state how many cars having upon them double-acting brakes are in use upon the Providence and Worcester Railroad.

A. Thirty-five.

Int. 29. Please state how many men are employed upon said road for the purpose of attending to the adjustment of the brakes on those cars.

A. Two men in Providence and two in Worcester. The two men we have in Providence spent only about two hours a day in adjusting the brakes of all the thirty-five cars.

Int. 30. What wages are paid these men per day?

A. We pay the first man $2.75, and the man under him $2.25 per day; that makes an average to each man of $2.50 per day.

Int. 31. How many hours is your working day?

A. Ten hours.

1590 Int. 32. Suppose the Springfield brake was in use upon all of these thirty-five cars, how many men, in your opinion, would it take to keep them in proper adjustment to run?

A. I should think it would take not less than five or six men, working all the time, and they couldn't half do it so that the cars could make good stops even then. I don't think there would be time enough between the coming in and going out of the trains for the men to adjust the brakes.

Int. 33. When you used the Tanner brake on your road, as you have previously testified in this case, how many cars had you with that brake on?

A. We had seventeen.

Int. 34. How many men did it require, and how much of their time was needed, to adjust the Tanner brakes on those seventeen cars?

A. Well, we employed one man at Providence, and nobody at all at Worcester, and he would not spend more than one hour a day in adjusting the brakes on those seventeen cars.

OLNEY L. SMITH.

(No cross-examination.)

***Deposition of Hervey Waters, recalled for complainant, taken at Boston, April 29th,* 1873.**

Direct examination by M'r Cozzens:

Int. 1. Please state whether you have examined the models introduced in this case on the part of the defendants, and marked "Defendant's Exhibits, Springfield brake, Numbers 1, 2, and 3," and whether you understand the construction and operation of the mechanism shown in said models.

1591 A. I have examined the models, and I understand the mechanism and modes of operation.

Int. 2. Please state whether you have also examined any car on the Boston and Albany Railroad which has upon it the brake known as the "Springfield brake," and also any other cars on said road; and, if so, please state when you made such examination, and whether you find any errors in any respect in any of the said models as compared with said cars.

A. I examined yesterday, April 28th, 1873, one of the cars having on it a Springfield brake on the Boston and Albany road, and some other cars that were standing with it, and I find that the model inquired of do not compare correctly with the cars as to the size or breadth of the passage-way between the cars of the train at the railing at the outer end of the platform. I found the cars were about twenty-three inches wide in that passage-way, and I find the models represent that passage-way as about thirteen inches or a little more. I also found that on the cars the windlassos for operating the brakes were considerably further out from the centre line of the car than is represented in two of the models, especially in the model "Springfield brake, No. 1," where the model represents the windlasses as about eighteen inches from the center line of the car, while in the car itself which had on the Springfield brake, this distance is about twenty-two inches. The model "No. 2" represents the windlasses about nineteen and one-half inches from the center line of the car.

Int. 3. Please state in what respect, if any, you consider these differences in the models to be important.

A. The importance to be attached to them is in connection with the windlasses themselves in their position to operate the brakes. It is one of the difficulties to be overcome (and which was overcome by the invention of Batchelder and Thompson) that the windlass is obliged
1592 to be considerably at one side of this passage-way, and conse-
quently considerably at one side from the central line of the car in the operation of the brakes; and in consequence of that position, considerable difficulty existed in the old Springfield brakes in the swiveling of the trucks as connected with the braking of the cars.

Now everything else being equal in the old Springfield brake, the nearer the windlass is to the central line of the car, the less difficulty there will be in operating the brake.

Int. 4. Please state whether any of the said models are so constructed that the line of draught from the windlasses to the tops of the truck-levers is or can be in line with the king-bolts of the car.

A. No; neither of them is so constructed.

Int. 5. M'r Henry Waterman, an expert on behalf of *of* the defendants, has testified in this case in his 36th direct answer, that "If the draft rod in the Springfield brake passes from the windlass to the top of the truck lever in a line with the king-bolt of the truck, * * the action upon the brake will not be seriously *e*ffected by the swiveling of the truck on passing from a straight line to a curve, or vice versa," and then, referring to defendant's exhibit "Springfield brake, No. 2," says: "Now, if I turn the top of the truck lever over until the tension rod practically passes through the line of the king-bolt, it is not practically affected at all by the swiveling of the truck. So with the action that takes place with the lever at the other end of the car—by turning the top of the lever over to bring the draft rod on a line with the king-bolt, it prevents the swiveling of the trucks from affecting the tension
1593 of the draft rod." Is said model "Springfield brake, No. 2," con-
structed so as to admit of any such operation as the witness

Waterman here describes? and if not, state what would have to be done to it in order to give it such operation.

A. As I understand M'r Waterman, he means to say that if these brakes were so constructed that the connecting rods from the windlasses to the truck levers drew in lines radial with the king-bolts, then the swiveling of the truck would not seriously affect the ten*is*on of those rods; and in that I think he is quite correct. But they are not so constructed. If the space between the connecting rods where they pass through the staples upon the body of the car be measured, it will be found about three and a quarter inches from centre to centre of the rods; and if the distance from the central line of the car to the centre of the windlasses be measured, it will be found one inch and five-eight's, which is half of the 3¼ inches. So there is no misunderstanding the construction of this brake apparatus in that respect. The connecting rods are made to draw parallel to the sides of the car and not radial to the king-bolts, and therefore in order to make them draw radial to the king-bolts the brake would have to be reconstructed.

Int. 6. You say in substance that in the old Springfield brake as it was organized, the draft of the rods connecting the windlasses with the truck levers could not be parallel to the sides of the car and radial with the king-bolt. Is it or not important in order to make a good brake the draft of such connecting rods should be parallel with the sides of the car and at the same time radical with the king-bolts?

A. It is important, because it is important that all the rods of the brake should pull parallel with the sides of the car; for it is important that the two rods which connect the two brake beams in the trucks should pull at right angles to the axles of the trucks (which will 1594 be parallel with the sides of the car), so as to pull the shoes properly upon the wheels and not bring them upon the wheels diagonally; and it is also important that the windlass rods should pull parallel with the rods connecting the truck levers so that the truck levers shall not be pulled sideways, but shall be pulled directly edgeways, in order to get the greatest strength and not bend them over sideways.

Hence it is important that all the rods of the brake should pull parallel with the sides of the car or parallel with the central line of the car—which is the same thing—and also that the rods connecting with the truck levers should at the same time pull radially to the king-bolts as nearly as may well be. Now both of these conditions cannot be obtained when the rods which connect directly with the truck levers are greatly to one side of the centre of the car—as they were in the old Springfield brake, because if they are and they do pull radially, then they will not pull parallel to the central line of the car, but diagonally to it.

Int. 7. M'r Waterman has also testified that as the Tanner brake is shown in the drawing annexed to the Tanner patent, the line of draft from the centre lever to the tops of the truck levers is, as he states, not in line with the kingbolts of the car. Will you please look at said drawing and state what will be the said line of draft according to the drawing.

A. On reference to the drawing, it will be seen that the points of connection of the brake-rods H 2 and G 2, with the break-levers of the trucks, are nearly in the central line of the car, and it will also be seen that the points of connection of those rods with the centre lever are a little to one side of the central line of the car; so that H 2 and G 2 do not pull parallel to the sides of the car absolutely, nor do they pull radial to

the king-bolts absolutely, but they do pull nearly radial to the king-
1595 bolts and nearly parallel to the sides of the car—both of which they
could not do if they occupied the position of the windlass connecting-rods D 2 and C 2, which are each removed out from the central line of the car as far as the windlasses themselves are, and as far as they were in the old Springfield brake; and is perfectly obvious, upon comparison of the rod H 2 with the rod D 2, that H 2 pulls substantially radical with the kingbolt, while D 2 is very far removed from such radial line, notwithstanding that both rods H 2 and D 2 are nearly parallel to the sides of the car; and this difference between the lines of draft of these rods H 2 and D 2 represents the actual differnace between the Batchelder and Thompson and the Springfield brake in respect to radial draft. There is not the slightest difficulty in understanding that difference; it is perfectly obvious that if the rod D 2 was connected with the truck lever at a point opposite to K 1 (where the rod H 2 connects with said truck), then the swiveling of the truck would affect much more sensible the tension of the rod D 2 than it now affects the tension of the rod H 2.

Int. 8. Please state whether in the above-mentioned models "Springfield brake Nos. 1, 2, and 3," there is any difference in organization; and also whether there is any difference in organization between any of said models and the old Springfield brake testified about at the trial at Albany on the Tanner patent, referred to in your sixth direct answer, on page 330, of the complainant's accounting record in this case.

A. All three of the models inquired of differ in their organization one from another. "No. 1" is substantially the same organization as the old Springfield brake which was described at the trial to which I refer in my sixth direct answer in this case, but the windlass in "No. 1" is at a greater distance from the truck of the car than it was in the old Springfield brake, so as to give considerably more length of chain in the
short direct connection to the nearest truck, and therefore the
1596 difficulty in the old Springfield brake is somewhat modified for
the better by that difference.

Int. 9. Please state whether in said models you find any inequalities in the wheels, and if so, state what effect such inequalities will have upon the working of the models in connection with the operation of the brakes?

A. The wheels in the models are not round. They were round when they were made, but the wood has shrunk and they have become oval, so that there cannot be any correct working of the models in connection with the brakes to show the general character of the contrivance, because the inequalities in the wheels consequent upon this shrinking will produce such an effect upon the shoes of the brakes as would be likely to mislead in any experiments made with said models upon the track when using the brakes.

HERVEY WATERS.

(No cross examination.)

Deposition of Edward Lang, recalled for complainant, taken at Boston, April 30th, 1873.

Examined by M'r Cozzens:

Int. 1. Will you please state how many cars having double acting brakes are running daily upon the Boston and Providence Railroad at the present time?

A. There are eighty, if not more.

Int. 2. Please state how many men are employed by said railroad company, to attend to the adjusting of the brakes on these eighty cars.

1597 A. I have three under me here at Boston, and M'r Lightner at Roxbury has five more; I think making eight in all.

Int. 3. About how much time per day is occupied by these eight men in adjusting the brakes on these eighty cars?

A. I should think fifteen minutes a day for each of the eight men would cover everything about the brakes, because some days it might take them half an hour to adjust the brakes on a train, and then they might not have to do anything to the brakes for two or three days; that is my best judgment. Fifteen minutes a day ought to give them plenty of time. It ought not to take a man a great while to adjust a Hodge brake.

Int. 4. You have heretofore testified about the Springfield brake, which were recently used for a short time on two of the cars of the Boston and Providence Railroad. Now, suppose that all these eighty cars you have spoken of were provided with Springfield brakes, about how many men do you think, from your experience with said two cars, would be required to keep those eighty Springfield brakes in proper adjustment for the cars to run?

A. Well, I make bold to say, about the Springfield brakes, that they would have to be adjusted every day, because, if you have any regard for the safety of your passengers, you must see that the Springfield brake is kept very nicely adjusted all the time, in order that it may have any efficiency. I think, to keep the Springfield brake properly adjusted on this number of cars—eighty cars—it would take five men all their time, every day; I wish to speak entirely within bounds.

Int. 5. How many hours constitute your working day?

A. Ten.

Int. 6. And what wages do the men who adjust the brakes on your road get, on the average?

A. Two dollars and a half a day.

1598 Int. 7. When the Tanner brake is adjusted on one car, about how long does it take to adjust it?

A. I should say six or eight minutes would be a fair average, to the best of my judgment.

Int. 8. How long is the main line of the Boston and Providence Railroad?

A. About forty-four miles.

EDWARD LANG.

(No cross-examination.)

Deposition of Thomas J. Hillock, taken at Boston, May 1, 1873.

Direct examination by M'r Cozzens:

Int. 1. Please state your name, age, residence, and occupation.

A. Thomas J. Hillock; age, 29; residence, East Cambridge; occupation, carpenter.

Int. 2. Have you ever been employed upon any railroad, and if so, what railroad?

A. I have been employed upon the Boston and Lowell and Nashua Railroad.

Int. 3. In what capacity were you employed on that railroad?

A. I was employed as a carpenter in the car shop.

Int. 4. How long were you employed there?

A. Nearly five years.

Int. 5. What sort of work did you do in the car shop?

A. Well, it was an assortment of work; new work and repair work—both together—on passenger-cars.

1599 Int. 6. Did this sort of work make you familiar with the arrangement, repairs, and adjustment of the brakes on said cars?

A. Yes, sir.

Int. 7. Do you remember that in the early part of 1872 there was a brake known as the Springfield brake put upon certain cars on the Boston and Lowell Railroad?

A. Yes, sir.

Int. 8. Please state who did the work of putting that brake on to those cars at that time?

A. John Copithorn and myself were the men.

Int. 9. Upon how many cars of said road was said brake put?

A. Four. It was the Lowell train; consisting of a baggage-car, two passenger-cars, and a smoking-car.

Int. 10. Please state, if you know, how these brakes answered as to working well or ill.

A. I should say that they worked badly; they could never make them work at all. I worked at them pretty much all the time they were on, and we adjusted them every day.

Int. 11. Please state whether you ever went out on the train upon which those brakes were used.

A. Yes, sir; I have been on the train two or three times.

Int. 12. At these times, or any of them, did you, yourself, apply those Springfield brakes?

A. Yes, sir.

Int. 13. Please state how they worked when you so applied them—as to holding the cars.

A. I should say they held something; I can't say how much they held; they held on one truck, but they did not seem to hold on the other much, if any—not sufficiently to break up that truck.

1600 Int. 14. You say you were on that train when those brakes were used two or three times; state how many times on these occasions you applied the Springfied brakes yourself?

A. I should say at least twice each time I was on the train. The engineers, brakemen, and baggage-master complained that the brakes were not any good; so I have gone out on the train a short distance and applied the brakes, but the engine would walk off the whole train with the brakes set on three or four cars.

Int. 15. State whether at any time, when you were on this train with the Springfield brakes, anything came under your own observation in reference to the brake being applied and the train running by stations.

A. They could not stop the train by shutting off the steam at the usual places when these brakes were; applied they would generally run by the station a little ways. This came under my own observation.

Int. 16. State whether at other times than when you were on the train yourself you have heard, after the train had got in, complaints from the brakemen in respect to the holding of the brake.

A. That was a common occurrence. It was most every day that complaints were made.

Int. 17. What were the complaints?

A. The general complaint was they did not work; they could not break the trains up in time to stop at the stations.

Int. 18. You have said just above that you worked on these brakes pretty much all the time they were on and that they were adjusted every day; state who, if anybody besides yourself, worked at adjusting these Springfield brakes.

A. Well, there have been a number out there with me; John Copethorn was one who worked with me.

Int. 19. For about how long a time did you work at the adjusting of these Springfield brakes?

A. I should judge about three months.

1601 Int. 20. While you worked at the adjusting of these Springfield brakes, how many men were engaged at a time in adjusting them?

A. Two.

Int. 21. Were the two men engaged in adjusting these brakes during all the time that was allowed for adjusting them?

A. Yes, sir; and then those cars have been set off once or twice for the purpose of adjusting the brake—left out of the train one day for the purpose of being adjusted.

Int. 22. Please state how long it would take to adjust these brakes on one car; doing the adjustment as well as you could.

A. Some days we could do it quicker than others, or we would have to get through quicker on account of the car not standing in the car-house long enough. The train would come in and change cars, and we had to work on them between times, while they would be shifting. I should say it would take from half to three-quarters of an hour to adjust the brakes on one car; I have had to go over to the depot sometimes to adjust the brakes when the train was taking in its passengers.

Int. 23. How long did it take to adjust the Springfield brakes on the four cars?

A. That is, to do them properly, or to do them just according to the time we had there; which do you mean?

Int. 24. According to the time you had there.

A. From half to three-quarters of an hour.

Int. 25. About how long did the train remain in the car-house for you to adjust the brakes?

A. From half to three-quarters of an hour.

Int. 26. All this time was spent in adjusting the brakes?

A. Yes, sir.

1602 Int. 27. How much of this half to three-quarters of an hour did each of the two men work at the adjustment of the brakes?

A. All the time; it took both of us all the time.

Int. 28. And did you, then, sometimes have to follow the cars out of the car-house to do still more adjusting?

A. Yes, sir.

Int. 29. Now, will you please answer how long you think it would take to adjust the brakes of those cars, "to do them properly," as you said above?

A. I should think it would take from a' hour and a half to two hours to go over the four cars.

Int. 30. And how much of this hour and a half to two hours for the four cars would each of the two men have to be occupied in the adjusting?

A. That is the time for the two men.

Int. 31. Each would be occupied all that time?

A. Yes, sir.

Int. 32. Please state how much care had to be taken with those Springfield brakes in adjusting them?

A. We were as particular as that we had to take our rule and measure both ends of our lever so we would have both rods of exact length.

Int. 33. Doing this, how equal were you able to get the adjustment as between the two trucks of the car?

A. We could get them equal; that is, in the position the cars stood in when standing still; but when the car would move both trucks were inclined to go backwards, so it threw the hind brake nigher to the wheel.

Int. 34. State what effect that had on the adjustment or on the equality of the power of the brakes on the two trucks?

A. It had this effect, that when you broke up on the lever they were not equalized so that the brakes of both trucks would brake together; that is, give the same power on the wheels of both ends of the car.

Int. 35. Were you able to overcome this difficulty?

1603 A. No, sir.

Int. 36. How hard did you try to overcome it, and to adjust the brakes so they would work well?

A. We used all the possible means we could use to overcome it.

Int. 37. State whether or not you were familiar with the business of adjusting car-brakes at the time you were set to work to adjust those Springfield brakes.

A. We had been accustomed to the Hodge brake. In adjusting the Springfield brakes, we went according to the directions of the foreman, M'r Benjamin C. Read, and there was also another gentleman, M'r Whipple, who came there occasionally. He was there at times I when made alterations in the arrangement of the brakes, also in the leverage of the brakes.

Int. 38. Why were these alterations in the arrangement and leverage of the brakes made?

A. To give the brake more power on the wheels, I should say—to give it more leverage. They altered the hole where it hauled from the centre.

Int. 39. State from whom these directions about the alterations in the arrangement and leverage of the brakes came.

A. M'r Whipple.

Int. 40. Were you present at any time when M'r Whipple gave any directions about these matters?

A. Yes, sir; there was one place—in the paint-shop—where we were making the alterations. I was there when the directions were given by M'r Whipple at that time.

Int. 41. Did M'r Whipple ever give you any directions about how to adjust the brakes?

A. Yes, sir.

Int. 42. About how frequently did he do this?

A. One time was the time we made the alterations; there was another time over at the Boston & Lowell depot.

1604 Int. 43. Do you remember that while those brakes were on the cars there was a week when they were making a test of them?

A. I think I do.

Int. 44. During that week how hard did you try, in adjusting the brakes, to make them work well?

A. We were particular in setting the rods, to have each brake have the same bearing on the wheels. We lengthened and shortened the rods by the rule so that each rod was the same length.

Int. 45. Are you still employed on the Boston and Lowell Railroad; if not, when did you leave there?

A. I am not. I left there in June, 1872.

Int. 46. Please state why you left.

A. I should say I left on account of not liking the work.

Int. 47. At the time you left the Lowell road, how many cars of the kind which usually have double-acting brakes upon them, namely, passenger-cars, baggage, mail, and express cars, and smoking-car, did the Boston and Lowell Company own?

A. There were 62 cars.

Int. 48. How many hours constituted a working-day on the Lowell road at the time you left?

A. Ten hours.

Int. 49. Suppose all of these 62 cars had on them Springfield brakes like those which were on the four cars above referred to—how many men working ten hours a day each, would it, in your judgment, take to keep the 62 Springfield brakes in such a state of adjustment as they ought to be in to run?

A. From five to six men.

1605 Int. 50. What are the average wages per day which the men who adjust the brakes on the Lowell road receive?

A. $2.75.

THOMAS J. HILLOCK.

(No cross-examination.)

Deposition of Jerry Peron, recalled on behalf of complainant. Taken at Providence, May 5, 1873.

Int. 1. Please state who adjusted the Springfield brakes at the time of the experiment made with it by M'r S. M. Whipple on the car on the Providence and Worcester Railroad on the 29th of March, 1873.

A. I did.

Int. 2. Please state whether M'r Whipple at this time gave you any directions as to adjusting it; and, if so, what were the directions?

A. Yes, sir; he told me to adjust it as nicely as I could.

Int. 3. How nicely or carefully did you adjust it?

A. I have had considerable experience in adjusting brakes—have been adjusting them a good while, and I adjusted this Springfield brake as perfectly as I could. When I got through there wasn't an eight of an inch difference between the eight shoes on the different wheels. That is about as close as you can get it.

Int. 4. State whether M'r Whipple was present while you were adjusting this brake.

A. He was, sir.

Int. 5. State whether, while you were adjusting this Springfield brake, M'r Whipple gave you any instructions about how to adjust it.

1606 A. Yes, sir; he told me how to do it—that is, to do it as carefully as I could; but he stood by me all the time.

Int. 6. After you had got the brake adjusted, what adjustment or regulation, if any, did you make as to the scales which were above the floor of the car?

A. We had the turnbuckle, and we adjusted the scales until they balanced, pound for pound. They were exactly alike at each end of the car. I looked at them before the car went out, and saw that everything was all right.

Int. 7. Please state about what distance this car with this Springfield brake on it thus adjusted, traveled from the place where you adjusted the brake to the bridge just at the end of the railroad-yard in Providence.

A. Just about a quarter of a mile, I should think.

JERRY PERON.

(No cross-examination.)

Subscribed before me this fifth day of May, A. D. 1873.

FRANCIS A. DANIELS,
U. S. Comm'r.

Deposition of Benjamin F. George, recalled for complainant. Taken at Boston, May 2, 1873.

Int. 1. Will you state the grades on the main of the Boston and Lowell Railroad line between Boston and Lowell?

A. There is no grade exceeding 25 feet to the mile.

Int. 2. How long is this heaviest grade of 25 feet to the mile?

1607 A. I cannot state the exact length, but it is only a short distance.

BENJ. F. GEORGE.

Deposition of Samuel B. Cushing, called on behalf of the complainant. Taken at Providence May 5, 1873.

Int. 1. Please state the radius of the "Eaton curve," so called, on the Providence and Worcester Railroad; of how many degrees it is, and which way it curves going from Providence to Worcester.

A. The "Eaton curve" is a four-degree curve, of fourteen hundred and thirty-two feet radius, and curves toward the right as you go from Providence to Worcester.

Int. 2. Assuming that upon curves upon a railroad chord-lines of thirty-five feet in length for each curve are measured, and that from the middle of these chord-lines to the rails of the respective curves lines at right angles with the chord-lines are measured, making the versed series of such curves respectively ten inches and six inches, what will be the radii in feet of such curves respectively?

A. The radius of the curve of which the versed line is ten inches will be one hundred and eighty-four (184) feet, and the radius of the curve of which the versed line is six inches will be three hundred and six (306) feet.

SAM'L B. CUSHING.

Subscribed before me this fifth day of May, A. D. 1873.

FRANCIS A. DANIELS,
U. S. Comm'r.

1608 *Deposition of Thomas Sayles, the complainant, recalled on his own behalf.*

Examined by M'r Cozzens:

Int. 1. State whether you have learned anything in relation to the Springfield brakes which have recently been upon certain cars of the Boston and Albany Railroad; if so, please state where you learned it, and what you learned.

A. I have; I saw from my own observation a few days ago that the

Springfield brake, which has recently been on car No. 124, on said railroad, had been takan off and the Hodge brake put in its place. I further learned to-day from the master car-builder at the shops of said company that the Springfield brake had also been taken off of the post-office car and the baggage-car of the train which formerly had on the Springfield brake, and that Hodge brakes had been put on in their places. I have also learned at the depot of the said company that the Springfield brakes were to be taken off of all the remainder of said cars and the Hodge brakes put on.

Int. 2. Please state whether you were present at the test of the Springfield brake upon a passenger-car on the New Jersey Railroad at Jersey City, about which M'r Charles Watts and M'r David H. Baker have heretofore testified in this case; and, if so, please state how such test come to be made and what you saw take place at said test.

A. I was present when said test spoken of was made. I asked the superintendent of the road to run the car out in a train to Newark and have the brake tried on the curve near Newark. He told me he would have the car run out and wished me to go out and see it tried. He told M'r Watts, who was depot-master there, to put that car into the 1609 train and run it out to Newark and try the brake. M'r Watts and I went out where the car was in order to attach it to the train that was about ready to start for Newark, and found that we hadn't time to get the car into that train. While we were standing there near the car, an engine backed down to hitch on to this car that had the Springfield brake on to attach it to some other train, and M'r Watts asked if we could not try it on a curve of the same track on which the car then stood. I told him I thought he could, but not so well as on the curve near Newark, for the curve, I didn't think, was so short as the Newark curve in the main line of the road. The engine was hitched to the car, and he then asked a man who stood on the car to apply the brakes while the car was being drawn from where it had been standing on the straight track. Before the engine was hitched to the car at this time at Jersey City, I had tried the brakes of the car and found that they were so nicely adjusted that I could not tell which truck they were applied to the hardest. The brake was applied while being drawn on the straight track before it reached the curve and the brakes set with the ratchet, not hard enough to slide any of the wheels. After the ratchet was set the car was drawn on the curve. When it commenced going on the curve one pair of wheels in the forward truck commenced sliding, and very soon the other pair of wheels commenced sliding. The engine drew the car on the curve until both trucks were fairly on the curve. All of the wheels of the forward truck were sliding when the car stopped. I then went to the rear truck and put my foot against one of the brake-beams, and found the brakes loose on the rear truck.

Int. 3. Please state whether the said Springfield brake on the car at Jersey City was arranged like either of the models put in evidence by the defendants in this case and marked "Springfield Brake Nos. 1, 2, and 3"; and, if so, which one was it like?

1610 A. It was put on similar to the brake on "Model Springfield Brake No. 1."

Int. 4. Please state whether any notice has been given to M'r S. M. Whipple, representing the defendants in this case, of taking of the testimony which has been taken on your behalf at New York on the 25th of April, 1873, and at Boston on and since the 26th of April, 1873.

A. I personally give M'r Whipple notice in Boston on the 23d of

April, 1873, that unless the defendants' time for taking testimony upon this accounting should be extended by the court beyond the 23d instant, I should take testimony in New York on the 25th and in Boston on the 26th instant. M'r Whipple at that time agreed to attend upon such notice. M'r Whipple and I then went to New York, and, after learning on the 24th that the defendants' time had not been extended, I again gave M'r Whipple notice in New York that I should take testimony in New York on the 25th and in Boston on the 26th of April, and I also subsequently caused notice to *to* the same effect to be sent to him in New York.

Int. 5. Also please state whether notice was given to said Whipple of the taking of the testimony which has been taken herein on your behalf in the city of New York on and subsequent to May 1, 1873, as appears by this accounting record.

A. I caused due written notice to be sent to M'r Whipple of the taking of the testimony inquired about in this question. It was so sent in abundant time to enable him to attend the taking of it, and he was in the city of New York at the time. On the evening of the first day of May, 1873, I saw him at the Astor House, and he then acknowledged to me that he had received the notice on the 29th day of April, 1873.

T. SAYLES.

1611 United States circuit court, northern district of Illinois.

THO'S SAYLES
vs.
C. & N. W. R'Y CO. } In chancery.

It is hereby stipulated between the parties to the above-entitled cause for the purpose of the hearing on complainant's claim for damages, that said defendants became a corporation and commenced running its cars and doing business on a portion of its railroad on the second day of June, 1859, and from that time until June 2d, '64, used on all of its passenger trains on its said road double-acting car-brakes known as the Stevens pat. brake; that such brakes were used on thirty-six (36) eight-wheeled cars running in its passenger trains, including all its passenger, baggage, and express cars. That it run four trains each day, and six cars in each train on an average. That during said 1612 period said defendants run a mixed train daily for freight and passengers, between Janesville and Chicago, being about ninety (90) miles, on which there was usually one passenger-car and one baggage, and that for one year during said period a similar train was run between Harvard and Rockford, the distance being about twenty-eight (28) miles, and that the baggage men on said two trains worked the brakes on said passenger and baggage cars. If extra passenger-cars were run the conductors of said trains acted as brakesmen on the extra cars. The remainder of said thirty-six (36) cars were in the shops for repairs or held in readiness for extra occasions. That each of said trains of six cars required and had two brakemen besides the baggage-man, who acted as brakeman on all of said trains. That defendant paid its brakemen an average of thirty-four dollars and forty cents ($34.40 c'ts) per month during said period of five years.

That during said period the actual cost of thirty-three-inch wheels, such as were used under the said thirty-six cars, was sixteen dollars and seventy cents ($16.70-100) each wheel, and that the cost of taking off old wheels and putting new wheels on the axles, was one dollar each wheel.

That on the 2d day of June, 1864, said def. consolidated its railroad and corporate franchises with the railroad and corporate franchises of the Galena and Chicago Union R. R. Co.; and the new consolidated company retained the corporate name of the def'ts.

WEST & BOND,
Soli. for Comp't.
(Signed) H. W. BLODGETT,
Def'ts' Att'y.

1613 U. S. circuit court, northern dist. of Illinois.

THOMAS SAYLES
vs.
THE C. & N. W. R. W. Co. } In chancery.

It is hereby stipulated between the parties to this cause, by their respective counsel, as follows:

First. That the stipulation made herein between said parties, on the twentieth day of March, 1867, in reference to the number of brakemen employed by the above-named defendants be amended, and it is now hereby stipulated that during all the time between the second day of June, 1859, and the second day of June, 1864, the said defendants employed on their railroad within said district, twelve regular brakemen for their passenger trains, besides the baggage-men on said passenger-trains, who also acted as brakemen.

Second. That during all said time, between the second day of June, 1859, and the second day of June, 1864, the said defendants used on their said railroad, at least two "way" or "caboose" cars, in their various freight trains, each of which cars had upon it a "Stevens'" double-acting car-brake.

Third. That during all said time, between the second day of June, 1859, and the second day of June, 1864, the said defendants removed the wheels of the thirty-six cars run in passenger-trains on their said railroad, as per former stipulation, as often as once or twice a year, sometimes oftener, on account of flat spots, which rendered them unfit for passenger-cars. Most of said wheels were then put under freight cars—under the end of said freight cars that had no brake on.

Dated May 10th, 1873.

WEST & BOND,
Comp't's Solicitors.
J. N. JEWETT,
Defe'ts' Solicitor.

1613½ THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILWAY Company. } In chancery.

Exhibit No. 8 in Supreme Court record.

W'M H. BRADLEY, *Clerk*

1614 United States circuit court for the northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILROAD Company. } In equity.

TESTIMONY TAKEN UPON THE ACCOUNTING IN THE CASE BEFORE H. W. BISHOP, ESQUIRE, MASTER IN CHANCERY.

S. D. Cozzens, of New York, counsel for complainant; S. M. Whipple, J. N. Jewett, of Chicago, counsel for defendants.

Filed May 19, 1873.

W'M H. BRADLEY, *Cl'k.*

1615 *Testimony on behalf of the complainant.*

Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILROAD Company. } In chancery.

JULY 19TH, 1871.

ASAHEL EMIGH, having been first duly sworn, was examined in chief by M'r Cozzens, and testified as follows, to wit:

Q. 1. What is your name, age, residence, and business?

A. Asahel Emigh; my age is 46; residence New York City; occupation real estate and patent rights.

Q. 2. In what way as to patent rights?

A. Owner and manager of a number of patent rights?

1616 Q. 3. Are you familiar with the letters patent granted July 6th, 1852, to Henry Tanner, as assignee of L. F. Thompson and A. G. Bachelder, for an improvement in car-brakes, and with the invention described therein?

A. I am familiar with the said patent and invention.

Q. 4. How long have you been so familiar with them?

A. About 16 years.

Q. 5. Will you please state upon what railroads, to your knowledge, the form of brake represented in the drawings of that patent, and technically known as the "Tanner brake," is or recently has been in general use, and upon what railroads is it in partial use?

A. It is in general use on the Camden and Amboy Railroad in the State of New Jersey; by the New Jersey Railroad and Transportation Company; it is in use on the Jamestown Road, and the Belvidere Road, both in the State of New Jersey; also in general use on a very large number of cars on the Pennsylvania Railroad; and in general use on the Louisville and Nashville Railroad; and in partial use on the Hudson River Railroad, on the Pittsburgh, Fort Wayne and Chicago Railroad, and on a few cars on the Chicago, Burlington and Quincy Railroad.

Q. 6. State, if you know, what is the fact as to the Tanner form of brake being in general use upon most of the railroads of the southern States?

A. The last time I was there, some years ago, I found it in quite general use; used on quite a large number of cars.

Q. 7. State whether you are interested in and managing the Stevens patent for a railroad-car brake?

A. Yes, sir.

1617 Q. 8. Have any of the railroads which use the Tanner brake, licenses under the Stevens patent?

A. A number of them have.

Q. 9. Please state as to whether you had knowledge, in or about the year 1862, as to the use of the Tanner brake upon railroads in the United States?

A. Previous to and at that time I knew of its general use upon the Providence, Hartford and Fishkill Railroad; the Camden and Amboy, the Providence and Stonington, the New Jersey Railroad and Transportation Company, the Jamestown Railroad, the Belvidere Railroad, the Lehigh Valley Railroad, the Augusta and Savannah Railroad, the Georgia Central, the Montgomery and Florida Railroad, the Mobile and Girard Railroad Company, the New Haven, Hartford and Springfield; and partially in use on the Providence and Worcester Railroad, and on the Boston and Providence Railroad, on the Long Island Railroad, the North Pennsylvania Railroad, the Pennsylvania Railroad, the Germantown and Norristown Railroad, the Richmond and Fredericksburg Railroad, the Wilmington and Manchester Railroad, the Selma and Alabama Railroad, the Reading Railroad, the Hudson River Railroad, the New York and Erie Railroad, the Buffalo and New York City Railroad, and the Elmira, Canandaigua and Niagara Falls Railroad.

Q. 10. State whether there are any of these roads mentioned in your last answer which you haven't visited since the last part of 1862?

A. I have not visited any of the roads mentioned in my last answer, south of the States of Kentucky and Virginia.

Q. 11. Any others?

A. Well, some of the roads in New England I have not visited nor examined since that date.

Q. 12. State, also, whether there are any of these roads enumerated in said answer which you have visited since 1862, respecting which it is not within your knowledge at the present moment what form of brake they use?

1618 A. I have a general knowledge of the brakes in use on all the roads which I have visited since that date; that is, as to the brake used at that time or soon after that time whenever I visited the roads up to the present. What they may use to day, I don't know. I know what they used very recently.

Q. 13. For about how many years have you been in the habit of visiting railroads with reference to car-brakes?

A. About 18 years.

Q. 14. According to your best observations during, say the last few years, how is the fact as to whether the use of the Tanner form of brake—the centre lever—has diminished or increased?

A. It has increased in its use for the last ten years.

Cross-examination by Mr. Jewett:

Cross-q. 1. Is or is not, the Tanner form of brake being superseded by other and better forms of brake?

A. It has been in many instances.

Cross q. 2. Is it as much in use now as formerly, in proportion to the extent of railroads; in proportion to the number of roads actually using brakes, is it as much now in use proportionally as it was formerly?

A. I think it is, in proportion to what it was ten years ago.

Cross-q. 3. I asked if it was as much in use now, in proportion to the number of roads actually using railroad car brakes, as it formerly was?

A. I think it is nearly as much as it was, in proportion, as it was at the time I first became acquainted with car brakes.

Cross-q. 4. The facts are, it has increased?

A. I think so; so far as my knowledge goes, it is used now ten times as much as it was ten years ago.

1619 Cross-q. 5. Is it used much, if at all, in the West?

A. It is used somewhat in the West; partially used on some roads, and wholly used, I think, on others.

Cross-q. 6. Is it used on any of the roads coming into Chicago?

A. It is in partial use on the Pittsburgh, Fort Wayne & Chicago road, or has been within the last two or three years; and it is used on a few cars on the Chicago, Burlington & Quincy Railroad, and on a number of roads running through Indiana and the southern portion of Illinois.

Redirect examination by M'r Cozzens:

Redirect q. 1. Do you happen to know whether it is in use on any of the through first-class express trains on the New York and Washington lines?

A. It is used on a large number of cars known as the through line going between New York and Washington—on the fast express trains between the two cities.

Redirect q. 2. State whether these trains are large, heavy, first-class trains?

A. They are large, heavy, first-class cars, and run at high rates of speed.

Redirect q. 3. Have or had any of the railroads over which the Washington lines run licenses under the Stevens patent during either the first term or the extension of that patent?

A. The Philadelphia, Wilmington & Baltimore Railroad Company have a license under the first term of the Stevens patent, that being one of the roads over which the through lines between New York and Washington runs. The other roads have no licenses.

Redirect q. 4. How long is the Philadelphia, Wilmington & Baltimore Railroad, and is it a first-class road?

1620 A. It is about ninety-eight miles long. It is a main line, and I consider it a first-class road.

Redirect q. 5. Please state, if you know, whether the Illinois Central Railroad Company has a license under the Stevens car-brake patent; and, if so, how long has it had such license?

A. About four weeks since, at the request of M'r Stevens, the patentee of the said patent, I called at the office of John Newell, the president of the Illinois Central Railroad Company, for the purpose of ascertaining what kind of a license, if any, said railroad company had under said Stevens patent. M'r Newell showed me their book of record containing patent licenses, and pointed out to me their record of the Stevens license in said book to their company. It was a full license for the first term of the Stevens patent, and for any and all extensions. It was dated about the year 1854.

Redirect q. 6. Please state what car brake is now in general use on the Illinois Central Railroad, if you know.

A. The Hodge brake.

Redirect q. 7. Please state to what extent, to your knowledge, the Hodge brake is now used in the United States.

A. It is in general use in the New England States and in the State of Ohio, and on many roads in the State of Indiana and in the State of Iowa, in the State of Missouri, and on the Union Pacific Railroad, and on a number of roads in the State of New York and the State of Illinois and the State of Michigan.

Redirect 8. Will you give some idea of about how long it has been in use in the parts of the United States mentioned?

A. As a general thing, since it was first introduced—say about eighteen fifty-four to the New England and Eastern States, and somewhat later in the Western States.

A. EMIGH.

1621 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company.
} In chancery.

JULY 20, 1871.

C. C. KELLOGG, being duly sworn, was examined in chief by M'r Sayles, and testified as follows:

Q. 1. State your name, age, residence, and occupation.

A. C. C. Kellogg; age, 38; residence, Chicago; secretary of the Barnum-Richardson Manufacturing Company.

Q. 2. Do your company manufacture railroad-car wheels?

A. Yes, sir; we have manufactured railroad-car wheels since 1862.

Q. 3. Did your company sell wheels to the Northwestern Railroad Company from 1862 to 1864, and did they buy old wheels of the company during that period?

A. They did.

1622 Q. 4. When you charged for new wheels from $16 to $18 each, what did you pay them for the old wheels?

A. From November, 1862, to December, 1863, we allowed the Chicago and Northwestern Railroad a cent and one-half per pound for old wheels. During that time the price for new wheels was from $15 to $18 each—thirty-three inch wheels.

Q. 5. Have you memoranda with you, taken from your books, of the price of the wheels?

A. Yes, sir.

Q. 6. During the period mentioned, when you charged them eighteen dollars apiece for wheels, in December, 1863, what did you allow them for old wheels?

A. One and one-half cents per pound.

Cross-examined by M'r Jewett:

Cross-q. 7. What is the usual weight of car wheels the size you mentioned?

A. Our wheels weigh from five hundred and five to five hundred and ten or fifteen pounds. They average about five hundred to five hundred and ten.

C. C. KELLOGG.

Subscribed and sworn to before me this 20th day of July, 1871.

Master, &c.

1623 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILroad Company.
} In chancery.

JULY 26, 1871.

Testimony of HENRY TANNER, called by complainant:

Q. 1. Please state your name, age, residence, and occupation.

A. Henry Tanner; age, 58; residence, Buffalo, N. Y.; occupation, general trader.

Q. 2. Are you the person to whom the letters patent known as the Tanner car-brake patent were issued as assignee on July 6th, 1852?

A. I am.

Q. 3. Have you at the present time any interest in that patent?

A. No.

Q. 4. Did you ever give any personal attention to the subject of railroad car-brakes, and to the introduction upon railroads in the United States of double-acting brakes for cars; if yea, when did you
1624 first give these matters attention, and for how long a period did you continue to be occupied with them?

A. I did, commencing in 1847, and ending, I think, in 1854. I devoted about all my time to that business.

Q. 5. State whether, during a part of this time, and, if so, for how much, you were engaged in introducing upon railroads in the United States double-acting car-brakes involving the invention patented in the said Tanner car-brake patent?

A. Well, about all the time; about all this time I was engaged in introducing that brake, or a brake in which that invention was involved.

Q. 6. While thus engaged, what portion of the railroads of the United States, if any, did you visit upon this business?

A. Well, I should say equal to three-quarters of what then existed in what we knew as the Northern States, outside of the slave States.

Q. 7. When you first went about to introduce the double-acting brake, what kind of brakes did you find in use upon the cars of the railroads you visited?

A. What is called the single brake, applying from the windlass to one truck.

Q. 8. State what you found, from your personal experience during this period of about seven years that you were engaged in introducing the double-acting brake upon these various railroads, to be the advantages which were derived by these railroads from its use, in respect of the number of brakemen necessary with it, as compared with the number necessary with the old single brake?

A. It did away with one-half the brakemen. It was almost universally so conceded at that time by railroad men in their statements to me about it.

Q. 9. How did you derive this knowledge and these acknowledgments that it did away with one-half the brakemen?

A. In the course of my business of introducing it and negotiating for the payment for it.

1625 Q. 10. At the time you commenced to introduce the double-acting brake, what was the average rate of speed of passenger-trains on railroads in the United States?

A. To the best of my recollection, about fifteen to twenty miles an hour when in motion.

Q. 11. About what, as nearly as may be, was the weight and length of passenger-cars then as compared with passenger-cars of the present time?

A. Well, I should judge they were double the heft now that they were then.

Q. 12. About what was the average weight of locomotives for passenger-trains at the time you commenced introducing the double-acting brakes?

A. Well, I should judge from ten to twelve tons.

(Cross-examination waived.)

HENRY TANNER.

Subscribed and sworn to this 26th day of July, 1871.

Master, &c.

1626 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company.
} In chancery.

JULY 27, 1871.

HENRY MORRIS, having been first duly sworn, was examined in chief by S. D. Cozzens, esq., and testified as follows, to wit:

Q. 1. Please state your name, age, residence, and occupation.

A. Henry Morris; 35 years; Janesville, Wisconsin; locomotive engineer.

Q. 2. How long have you been employed as a locomotive engineer, and on what railroads?

A. About eleven years; on the Northwestern Railroad—on the Wisconsin division.

Q. 3. Please state, if you know, at what rates of speed the passenger-trains ran on that road from 1859 to June, 1864.

A. From twenty to twenty-two miles an hour; that included stops.

Q. 4. What was the speed of running-time of those trains?

A. About from twenty-four to twenty-five miles an hour.

1627 Q. 5. What was the weight of the engines attached to these trains during that time—the average weight?

A. From twenty-six to twenty-eight tons.

Q. 6. How many stations at which passenger trains stop were there on the Wisconsin Division of the Northwestern Railroad, between 1859 and June, 1864?

A. I can tell you the number from Chicago to Oshkosh, but not beyond there; there were thirty stations from Chicago to Oshkosh, at that time, at which passenger trains stopped.

Q. 7. What is the distance on the railroad from Chicago to Oshkosh?

A. One hundred and ninety-three miles.

(Cross-examination waived.)

HENRY MORRIS.

Subscribed and sworn to this 27th day of July, 1871.

Master, &c.

1628 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company.
} In chancery.

JULY 27TH, 1871.

Examination of W'm T. Ragland:

Q. 1. What is your name, age, residence, and business?

A. William T. Ragland; age, 55; residence, Bloomington, Illinois; occupation, machinist.

Q. 2. Have you ever been employed upon railroads; and, if so, please state upon what railroads, and about when you first commenced to be so employed?

A. I have been employed on different railroads: the Hudson River; Albany & Schenectady; Chicago & S't Louis; Bloomington & Alton Railroad—I built that road. I commenced to be employed on railroads somewhere about 1841 or 1842.

Q. 3. In what capacity or capacities were you employed on these railroads?

1629 A. On the Hudson River Railroad I had the superintending of the building and repairing of all the cars. On the S't Louis road, I was the superintendent of machinery, of the engines and cars—all the rolling stock.

Q. 4. For about how many years in all did you continue to be employed upon the various railroads mentioned?

A. Somewheres in the neighborhood of 26 years.

Q. 5. State whether your experience on the railroads which you have mentioned has made you acquainted practically with the different kinds of car-brakes used on railroad cars in the United States; if so, state what are some of the different forms of car brakes with the use of which you are practically acquainted?

A. I have become practically acquainted with the car-brakes used in the United States—those that are in general use.

First among the number is the brake known as the single hand brake operating on four wheels; the next is the Tanner brake, operating on eight wheels from either end of the car; the next is known as the Hodge brake, operating on eight wheels of the car from either end of the car; the next is the Stevens brake, also operating on eight wheels from either end of the car.

Those are the four that I am most familiar with in practical use.

Q. 6. Please state for about how long you have been familiar practically with these various forms of brake?

A. I am acquainted with the single hand brake operating on four wheels since I first went in the employ of the railroad companies in 1842, or about that. I became acquainted with the Tanner, Hodge, and Stevens brakes about the years 1850 to 1852. I have been acquainted with them from that time to the present.

1630 Q. 7. While you were employed on the Hudson River Railroad, were you ever at any time called upon to make any practical comparative tests between the old single acting brake and the Tanner and Hodge brakes in reference to the wear and durability of the car-wheels of cars with the said brakes respectively; and, if yea, state about when you made those tests and upon what kind of cars the tests were made?

A. Yes, I did make some tests. I think it was in the spring of 1852. I made the tests upon passenger, baggage, and mail cars.

Q. 8. For about how many months did those tests continue?

A. During that summer. Probably four months. I should say about four months.

Q. 9. Were said tests under your charge and direction during the whole of this time?

A. They were under my direction.

Q. 10. Did any person request or instruct you to make those tests, and, if so, who?

A. They were made at the suggestion of the superintendent of the road.

Q. 11. State how you found the fact to be from those tests as to whether the car-wheels would last longer without injury when the Tanner brake was used on the cars than when the old single acting brake was used on the cars?

A. They lasted longer with the Tanner brake than with the old single brake.

Q. 12. Now, from the experience and knowledge derived by you from those tests, how many more sets of eight wheels for a passenger car would be required in a year with the old fashioned single brake on the car, than upon the same car in a year with the Tanner brake, assuming that the cars were of the ordinary weight, and that the speed at which they were run would be twenty miles per hour including stops?

A. Four sets of wheels with the single brake to one set with
1631 Tanner brake. I am basing this answer on the tests I made. In
other words, I mean that with the single brake three sets of wheels more would be required on a passenger car in a year than would be required on the same car in the same time with the Tanner brake. A set of eight wheels under a passenger car under the circumstances assumed would last about a year.

Q. 13. State whether you found in the tests mentioned any essential difference between the durability of the wheels when the Tanner form of double brake was used and when the Hodge form was used.

A. There was no material difference in the wear of wheels between either of those brakes, the Tanner and the Hodge.

Q. 14. Will you please state what are the reasons why the wheels last so much longer when the Tanner brake is used than they do when the single brake is used?

A. The difference is in the construction of the two brakes. With the old single brake all the force exerted on the windlass is applied to the pair of brake-clogs that connects with the fulcrum of the lever, thereby exerting a force sufficient to stop the rotation of the wheels, causing a flat spot to be worn on the outer periphery, thereby making the wheels unsafe for passenger-cars. With the Tanner brake, the lever is so arranged that the power is more equally divided up between the eight wheels under the car, and does not produce the effect of sliding the wheels to so great an extent.

Q. 15. State whether the passenger-car wheels slide somewhat when the Stevens brake is used.

A. Not where the levers are properly arranged, and no more force exerted than one ordinary man is capable of doing. As the Stevens brake is ordinarily arranged, the wheels do sometimes slide.

1632 Cross-examined by M'r Jewett:

Cross-q. 1. Which is the better brake, the Stevens or the Tanner?

A. I think the Stevens brake is the best brake.

Cross-q. 2. Which is the better brake, the Tanner or the Hodge brake?

A. I don't think there is any material difference between them two brakes.

Cross-q. 3. Which brake did you adopt after the tests you referred to?

A. The Stevens brake.

Cross-q. 4. Where were those tests made?

A. On the Hudson River Railroad.

Cross-q. 5. At what place on the road were they originated?

A. At Thirty-first street, corner of Tenth avenue, at the shops in New York City—at the shops of the company.

Cross-q. 6. Who assisted in making them?

A. Several men. I don't remember their names.

Cross-q. 7. Who was the superintendent of this road who ordered the tests?

A. Oliver H. Lee.

Cross-q. 8. Where is he now?

A. I think he is somewhere in Chicago—I would not be positive. I meet him here once in a while. I believe he has gone out of the railroad business altogether.

W'M T. RAGLAND.

Sworn to and subscribed this 27th day of July, A. D. 1871.

H. W. BISHOP,
Master in Chancery.

1633 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company.
} In chancery.

JULY 29, 1871.

WILLIAM GUNTHER, being first duly sworn, was examined in chief by S. D. Cozzens, esq., and testified as follows:

Q. 1. What is your name, age, business, and place of residence?

A. William Gunther; age 39; car-repairing; residence, Chicago.

Q. 2. Are you employed upon any railroad; and, if so, upon what railroad?

A. I am—on the Wisconsin division of the Chicago and Northwestern Railroad.

Q. 3. Do you have anything to do with looking after the wheels of the passenger-cars on that railroad; if so, what do you have to do about the wheels?

A. I do; I look the wheels over.

Q. 4. How often do you look the wheels over?

A. Every time the cars come in.

Q. 5. Do you have a gang of men under you doing this work of inspecting the car-wheels?

A. Yes, sir.

1634 Q. 6. How many men are there in that gang; and who is the foreman of the gang?

A. There are four men, and I am the foreman of that gang.

Q. 7. How often, on the average, do you have to remove the car-wheels from under the passenger-cars on said Wisconsin division ?

A. Every four months, about, on an average.

Q. 8. What is the matter with the wheels which causes you to remove them thus often ?

A. They get "spotted."

Q. 9. After they get "spotted," are they considered unfit to run in passenger-trains?

A. Well, they are not fit to run.

Q. 10. How long have you been employed on the Wisconsin division of the Northwestern Railroad, looking after car-wheels ?

A. Eleven years.

Q. 11. You were looking after car-wheels on that division, were you, between 1859 and 1864 ?

A. Yes, sir.

Q. 12. State whether there was any difference about the "spotting" of the wheels on that division between the time from 1859 to 1864, and the present time.

A. Well, I don't think there was much difference.

(Cross-examination waived.)

WILLIAM GUNTHER.

Subscribed and sworn to this 29th day of July, 1871.

H. W. BISHOP,
Master, &c.

1635 U. S. circuit court, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company.
} In equity.

Testimony upon final accounting before the master, taken in the city of New York, in pursuance of agreement between the counsel for the respective parties above named, this fifth day of September, A. D. 1871, as follows:

SAMUEL THOMAS, a witness duly called and sworn on the part of Thomas Sayles, the above-named complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation ?

A. Samuel Thomas; I am forty years of age; residence is Jersey City; and my occupation is that of a car-inspector.

2. Q. What cars, or what trains of cars, do you inspect ?

A. I inspect all the cars of the New Jersey R. R. Co., and of the Camden and Amboy R. R., which come into Jersey City—except the cars of the Washington line.

1636 3. Q. For about how long have you been employed in inspecting the cars you have above referred to ?

A. Since 1853, off and on, and for the last eleven years all the time.

4. Q. Did you, at any time, have charge of inspecting the cars of the Washington line; if so, at what time was it ?

A. I had charge previous to M'r Van Doren taking it.

5. Q. For about how many years did you have charge of inspecting the cars of the Washington line ?

A. I couldn't state exactly, but it was two years certainly, perhaps longer.

6. Q. During the time you inspected the cars of the Washington line, what were the kinds of double-acting brakes which were on the cars of that line?

A. They were such as they are using now on the Camden & Amboy cars and the New Jersey cars; and we had on some of the Philadelphia, Wilmington & Baltimore cars a brake with a long rod running through from one truck to the other.

7. Q. In inspecting these cars of the Washington line, what were your duties—what did you have to do to the cars?

A. I had to see that the cars were all in right order to run—the wheels and brakes.

8. Q. State whether you had to take out the wheels when they were worn too much to run properly, and put others in their place.

A. I had to notify M'r Baker or M'r Brown.

9. Q. Notify them about what?

A. That they wanted a new pair of wheels.

10. Q. When you so notified M'r Baker or M'r Brown, what did they do?

A. They sent men to take them out and put new ones in.

11. Q. While you had charge of inspecting the cars of the Washington line, did you, or not, find any difference in the length of time the
1637 wheels would wear in the cars of that line furnished by the Philadelphia, Wilmington and Baltimore road, having the brake with the long rod running from one truck to the other, of which you have spoken, and the cars of the Camden and Amboy and the New Jersey roads running in that line?

A. Well, I think the wheels of the New Jersey cars will wear better than the Camden and Amboy wheels. I don't know as I could say about the difference between the cars of the Philadelphia, Baltimore and Wilmington road, and the cars of the New Jersey and Camden and Amboy roads.

12. Q. State whether or not you were able to see any difference in the wear of the wheels of the Philadelphia, Wilmington and Baltimore cars, and of the cars of the New Jersey road in that line.

A. I don't think I could see any difference.

13. Q. About how long, on an average, did you find that the wheels of the New Jersey cars in that line would last to run properly?

A. Well, I think the wheels would run about a year on an average; sometimes they would run longer and sometimes shorter, but about a year on an average.

Cross-examination by S. M. Whipple, esq.:

1. Cross-q. Is there any difference between the brakes on the Camden and Amboy cars and the New Jersey cars?

A. The connections are the same.

2. Cross-q. Has the brake in both cases a center lever connection?

3. Cross-q. Have you kept any account, or have you any facts, by which you are enabled to say that the wheels last as well on the cars of the New Jersey road as those on the cars of the Philadelphia, Wilmington and Baltimore road?

A. I haven't kept any account of them.

1638 4. Cross-q. By what method do you come to the conclusion that the wheels on the New Jersey road and Camden and Amboy last about a year?

A. I judge from about the time the cars come out of the shop with new wheels.

5. Cross-q. Have you made a minute of the time said cars came out with said new wheels, and also the time that such wheels were worn out and had to be replaced with new ones?

A. Well, I have frequently asked the boss painter when such cars came out, and he has told me a year, and sometimes a little over a year.

SAMUEL THOMAS.

JOHN P. VAN DOREN, being duly called and sworn on the part of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. John P. Van Doren; age, forty-six; residence, 223 South Eighth street, Jersey City; occupation, car-inspector for the New York and Washington air-line at Jersey City.

2. Q. How long have you been car-inspector for that line?

A. I have worked on that line more or less since it run in there, but I have been hired and paid by the line, separately, since a year ago last February.

3. Q. What are your duties as car-inspector of that line?

A. All repairs of the cars come under me—wheels, trucks, cleaning inside and out, keeping them in perfect order. And, also, making up all the Washington trains.

1639 4. Q. State whether it is within your duties as car-inspector of that line to have the wheels taken out when they are worn too much to run properly, and new ones put in their places.

A. It is.

5. Q. State what are the different kinds of brakes used on the cars of the Washington line, since you have had charge of it.

A. They have on the cars of the Philadelphia, Wilmington and Baltimore road what they call the Stevens brake; the rod running from one truck to the other, without a lever in the center of the car. The New Jersey and the Camden and Amboy have a brake with a lever in the center of the car.

6. Q. Is this brake with the lever in the center of the car sometimes called the "center-lever brake?"

A. I think it is.

7. Q. State whether, since you have been inspector of the Washington line, you have found any difference in the length of time the wheels wear under the cars of the Philadelphia, Wilmington and Baltimore road, with the Stevens brake, and the cars of the New Jersey and Camden and Amboy roads, with the center-lever brake.

A. I have not, with the exception of some poor wheels of the Camden and Amboy road; they did not wear so long as the wheels of the Philadelphia, Wilmington and Baltimore cars. They broke out in the tread.

8. Q. Did you find any difference in the length of wear between the wheels of the cars of the roads inquired about in the case of the good wheels? Not these poor ones.

A. I did not.

9. Q. About how long, on an average, do you find that the wheels of the cars in the Washington line having the center-lever brake, wear?

A. Well, I have had some that wore as long as two years, and some that only wore three months. I should think about a year was the average of them.

1640 10. Q. What wheels was it that you found wore only three months?

A. Wheels that had some defect in them, loose wheels, wheels that broke out in the tread, and cracked wheels.

11. Q. What I want to know is what is the average length of wear of the wheels in the cars with the center-lever brake, when the wheels are not defective, and taking the cars on the whole?

A. I should think about a year.

12. Q. Do you keep any accounts of the wheels that you have taken out and put into these cars of the Washington line?

A. I do.

13. Q. Please state what kind of accounts you keep of them.

A. Accounts of every car and every wheel they are taken out from. I take the number of every car they are taken out from. I have a regular book, and take the day of the month the wheels are taken out, and the number of the car they are taken from.

14. Q. Please state whether you find any advantage in the use of the center-lever brake over the Stevens brake in reference to taking up the slack of the windlass chains, and in reference to the overlapping of the windlass chains on the windlass staff.

A. In the Stevens brake we are more troubled with it on the short curves in Baltimore; it stalls the horses so that we have to disconnect the rods to get them through the city sometimes.

15. Q. Is there any trouble of this kind with the center-lever brake?

A. No, sir; we hear no complaints of it.

16. Q. What is it which causes this trouble with the Stevens brake?

A. You have got to have your rods up so short that they won't let the truck twist enough to turn the curves.

17. Q. Why is it that you have to have your rods up so short?

1641 A. You have no power on them to apply the brakes to the wheels if you don't keep them up short.

18. Q. Suppose you let the rods out, what would be the result? I mean let the rods out so that the car-trucks would go very easily round the curves.

A. Your brake chains would wind up on your brake-shaft so that you couldn't get any power on your brakes. If you get them too slack your brake-levers will also draw right over against the cross-timbers of the truck-frame.

19. Q. In applying the brake to stop the car, which brake requires the most slack to be taken up, the center-lever brake or the Stevens brake?

A. The Stevens brake.

20. Q. State whether or not this having less slack to take up is an advantage in the center-lever brake; and, if so, why.

A. It is an advantage, because it is less work to keep it in repair.

21. Q. In which brake will the brake-shoes be made to bear quickest upon the wheels, from the time the brakeman commences to turn the windlass?

A. There is a good deal of difference in that whether the Stevens brake is in perfect order or not. The center-lever brake applies the quickest.

22. Q. What is the quicker application in the center-lever brake due to?

A. Well, I think on account of having the centre lever. In the Stevens brake you have got to catch your connection, and pull clear through to the other end of the car before you can get your brakes up.

23. Q. About how much more slack does this make necessary to be

taken up in the Stevens brake than in the center-lever brake, before the brake-shoes are brought up against the wheels?

A. There is from four to six inches more in the Stevens brake.

1642 24. Q. State whether or not it is this less slack which has to be taken up in the center-lever brake which causes that brake to apply the brake-shoes quicker than the Stevens brake.

A. I think it is.

25. Q. Please state which of the two brakes, the Stevens or the center-lever, is kept in order with the least expense, according to your experience with the Washington line.

A. The center-lever. I don't have half the complaints from them that I do from the Stevens brake. There are complaints every day from them.

26. Q. Why is it that the Stevens brake costs more for repairs than the center-lever brake?

A. The whole thing is on account of curves in the road in the streets of Baltimore; they tear the rods off when they are too tight. On the straight track they will run well enough, but when they get on those sharp curves, going around the corners of the streets, they stall the horses so that they can't get around the curves, and then the men get mad and tear the rods off, and the cars come through all the rest of the way without any brakes. As soon as the rods are disconnected the brakes are good for nothing. This happens often, and gives a great deal of trouble.

JOHN P. VAN DOREN.

(Cross-examination waived.)

George W. Brown, being duly called and sworn on the part of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

1643 A. George W. Brown; age, forty-two; residence, Harrison, New Jersey; occupation, that of car-builder.

2. Q. In what shop are you employed; how long have you been employed there, and what position in that shop do you hold?

A. In the shop of the New Jersey Railroad and Transportation Company, in Jersey City; have been employed there twenty-one years, and I am assistant foreman in said shop.

3. Q. About how many years have you been assistant foreman there?

A. About thirteen years altogether.

4. Q. What kind of work do you have in your charge, as assistant foreman in that shop?

A. All the repairs pertaining to cars—the passenger and freight cars.

5. Q. Do you also build new cars in that shop—both freight and passenger?

A. Yes, sir; I do.

6. Q. What kind of brakes are used on the passenger cars of the New Jersey Railroad?

A. The center lever brake.

7. Q. Is this brake sometimes called the Tanner brake?

A. It is.

8. Q. How many cars, altogether, are there upon the New Jersey road at the present time, running in the passenger trains?

A. We have got about one hundred cars, belonging to the New Jersey road.

9. Q. How many of these cars have the Tanner brake?

A. Pretty much all of them.

10. Q. State whether the majority of the passenger trains run by the New Jersey Railroad Company are what would be called heavy trains?

A. Yes, sir.

1644 11. Q. What kind of brakes are used upon the passenger cars belonging to the Camden and Amboy road?

A. The center lever brake—those that run over our road.

12. Q. When did you first go into the employ of the New Jersey Railroad Company?

A. July 10th, 1850.

13. Q. At that time, what kind of brakes were in use upon the passenger cars of that road?

A. There were single brakes, working on one track.

14. Q. At that time did you have anything to do with the repairs of these passenger cars with the single brake; if so, where, and for about how long?

A. I did; at the car shop in Jersey City, and up to the time we put on the double-acting brakes.

15. Q. At that time how many cars were there running in passenger trains, belonging to the New Jersey road?

A. About thirty.

16. Q. While these passenger cars were used with the single brakes, how often, on an average, did you have to take out the wheels because they were worn too much to run properly? Answer, taking the average of all the passenger cars then belonging to the road.

A. From four to six months, as near as I can get at it. Our wheels were not so good then as they are now.

17. Q. Since you have been using, on the New Jersey road, the Tanner brake, how long do you find that the wheels of the cars running in the passenger trains, to which the brakes are applied, will wear, on an average, without requiring to be taken out?

A. They wear a year.

18. Q. Was the speed of the passenger trains of the New Jersey road, at the time when they used the single brakes on those trains, the same or less than it is now?

A. It was less, to the best of my knowledge.

1645 19. Q. Do you know about what the speed of those passenger trains was then?

A. From twenty to twenty-five miles per hour on the Philadelphia trains.

20. Q. About what is the speed of the passenger trains on the New Jersey road—the Philadelphia trains—now?

A. About thirty miles per hour.

21. Q. Were the passenger trains on the New Jersey road at the time they used single brakes as heavy as they are now?

A. No, sir; they were not. The cars did not begin to be as heavy.

22. Q. State what effect, if any, this greater speed and greater weight of trains has upon the wearing of the wheels by the application of the brakes?

A. The additional heft and additional speed in coming to a stop—applying the brakes—wears the wheels.

23. Q. Does it wear them less or more than when the weight and speed are not so great?

A. The greater speed and weight wears them the most.

24. Q. Suppose the passenger trains, as they are with their present weight and speed, on the New Jersey road, had single brakes; state whether or not the wheels would wear out quicker, in your judgment,

than they did at the time when the single brakes were used on the passenger trains and the speed and weight of the trains were less?

A. I think they would wear out quicker.

25. Q. Are you familiar with the Stevens brake?

A. I have worked some with it.

Q. 26. Are you sufficiently familiar with it to say whether or not there is any advantage in the Tanner brake over it, in respect to the quickness with which the brake-shoes can be applied to the wheels?

A. I have tried it, and find I can put on the Tanner brake quicker than I can the Stevens brake, on account of the surplus chain in the Stevens brake. 1646

27. Q. State whether or not this is an advantage in the Tanner brake?

A. I think it is.

28. Q. Please state whether or not there is any advantage in the Tanner brake over the Stevens, in respect to the winding of the windlass chain around the windlass shaft; and, if so, please state what it is.

A. There is; in winding that surplus chain in the Stevens brake around the windlass shaft, we can't get the purchase on the wheels.

29. Q. What is the usual diameter of the windlass shaft?

A. On the New Jersey cars, about an inch and a half at the part where the chain winds round.

30. Q. In the Stevens brake, when the surplus chain is wound up around the windlass shaft, about what have you found to be the diameter or thickness at the part where the chain is wound, counting both shaft and chain?

A. Well, I suppose it would be in the neighborhood of five inches.

31. Q. About what is the diameter or thickness, in the Tanner brake, when all of the chain which is necessary to wind is wound around the shaft, counting both shaft and chain?

A. Not three inches. When the brake is in order, and it is wound up solid, we don't calculate to have more than three, or four, or five links of the chain around the shaft.

Cross-examined by M'r Whipple:

1. Cross-q. Do you know anything about the Stevens brake beyond what you have seen of its operation on the cars of the Philadelphia, Wilmington and Baltimore Railroad, which cars run in the through Washington line?

A. I do not, outside of the Washington line.

1647 2. Cross-q. In what way do you come to the conclusion that the wheels when used under the single brake, prior to your putting on the double brake, wore out after four to six months' use?

A. For the reason they had so much more purchase by braking on one truck, and sliding the wheels in stopping the trains.

3. Cross-q. Do you know that the wheels wore out in from four to six months, or is it only your opinion that such was the case?

A. To the best of my knowledge they were taken out as often as that.

4. Cross-q. Did you keep an account at that time as to the time when the wheels were put into a car, and when they were taken out to be replaced by others?

A. I did not, particularly, only by the oftenness we worked on the cars.

5. Cross-q. What do you mean by the oftenness you worked on the cars?

A. I mean putting new wheels in the same cars.

6. Cross-q. May not many of the wheels, then, at that time, have lasted more than four or six months?

A. There might, some more and some less.

7. Cross-q. Were the wheels at that time, in your judgment, as good as those now in use?

A. Some were and some were not, to the best of my knowledge. Some were very good wheels, and some were very poor ones.

8. Cross-q. Was the failure of the wheels, at that time, owing to the use of the single brake alone, or did other causes produce this failure? Please explain.

A. I think it was the use of the single brake in the sliding of wheels.

9. Cross-q. Did you have occasion to take out wheels injured from any other cause than the use of the single brakes?

1648 A. We did sometimes—loose wheels, sometimes cracked wheels.

10. Cross-q. How long would wheels last, on an average, to which no brakes were applied?

A. From a year to two years; may be longer, may be shorter.

11. Cross-q. How do you arrive at such a conclusion?

A. By wheels we have taken out; middle wheels in our six-wheel trucks.

12. Cross-q. Do you find that middle wheels wear longer than outside wheels?

A. We do.

13. Cross-q. Have you noticed any difference in the wear of the wheels on the inside of the truck, as compared with the outside wheels of the same truck?

A. No, sir.

Redirect:

1. Re. q. Please state about how many inches on the truck-lever, from the centre of the point of connection of that lever to the brake-beam, the connection is placed from that truck lever to the opposite brake-beam of the same truck, on the New Jersey road?

A. Six inches and a half.

2. Re. q. What is the distance from said connection with the other brake-beam, to the top of the truck lever?

A. About twenty eight inches.

3. Re. q. State whether this relative proportion of the two arms of the truck lever tends considerably towards equalizing the pressure upon the two brake-beams?

A. It does.

4. Re. q. When you testified in your direct examination about the wear of the wheels with the single brake, did you refer to the loose wheels and the cracked wheels, or to the average wheels which were in good condition, not loose or cracked?

1649 A. I referred to all the wheels which were taken out, to the best of my knowledge.

5. Re. q. What I mean is, did you, in speaking of the wheels which were worn out by the single brake, refer to any wheels other than those which were kept in the cars till they were worn out?

A. In speaking of that, I mean all the wheels we took out.

6. Re. q. Will you please now refer only to wheels which were in good condition, not cracked or loose, and state how often they had to be renewed on the average when the single brake was used?

A. I can only say what I said before, from four to six months, to the best of my knowledge.

7. Re. q. In what year, or about what year, was the use of single brakes given up on the New Jersey road?

A. Along in 1856 or 1857, before we got them all off, as near as I can remember. It was in 1851 that they put the first double brakes on.

GEORGE W. BROWN.

Adjourned to Sept. 12th, at 10.30 a. m.

1650 NEW YORK, *Tuesday*, *Sept.* 12, 1871.

JOHN B. HILL, being duly called and sworn on the part of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. John B. Hill; age, thirty-six; residence, Washington, D. C.; occupation, car-builder.

2. Q. How long have you been a car-builder?

A. I have been a car-builder six years. Before that, I served my apprenticeship as a coach and omnibus builder. I have also been engaged in building street-cars.

3. Q. By what corporation are you at present employed?

A. The New York and Washington air-line.

4. Q. Is that the corporation or consolidation of companies that manages the through lines between New York and Washington?

A. Yes, sir.

5. Q. What are the duties which you perform for the New York and Washington air-line?

A. Inspecting and superintending repairs and cleaning of the cars in the through lines between Washington and New York.

6. Q. State what duties these "repairs" include?

A. Putting in wheels, and casual repairs.

7. Q. About how long have you been engaged in these duties, and where are you stationed to perform them?

A. Two years; at Washington Station.

8. Q. Is there anybody else who has anything to do with these duties as to these through lines at Washington?

A. No, sir.

1651 9. Q. Who is the party who performs the same duties as to these through lines at Jersey City, the other end of the route?

A. John P. Van Doren.

10. Q. Is there anybody but M'r Van Doren who has anything to do with these repairs at Jersey City?

A. Nobody else.

11. Q. Are you familiar with the different kinds of car-brakes used on the cars of these through lines?

A. Yes, sir.

12. Q. What kind of brake is used on the cars in these lines belonging to the New Jersey and Camden & Amboy railroads?

A. The center lever, double-acting brake.

13. Q. What kind of brake is used on these cars in these lines belonging to the Philadelphia, Wilmington and Baltimore road, and the Baltimore and Ohio road?

A. What is called the Stevens brake.

14. Q. State whether you make written statements of the number of car-wheels which you take out and replace by new wheels in the cars of said lines, and of the cars from which you take them out; if so, how often do you make up such statements?

A. I do; on or about the first of each month.

15. Q. State how long you have been keeping written accounts of the number of wheels taken out of these cars?

A. At least a year and a half.

16. Q. Please state whether these duties of yours require you to observe the wear of the car-wheels in these through cars, from the application of the brakes to them?

A. Yes, we examine the wheels thoroughly every day. I do it myself with others to assist me.

17. Q. State whether you find any difference in the length of time which the said car-wheels wear—so far as regards the effect produced
upon them by the application of the brakes—between the wheels
1652 of the cars which have the center lever-brake, and those which
have the Stevens brake?

A. There is no difference.

18. Q. State about how long the car-wheels in those lines last, on the average, before requiring to be replaced by new ones?

A. About twelve months.

19. Q. Do you apply this last answer to all the cars alike—those with the centre-lever brake and those with the Stevens brake?

A. Yes.

20. Q. In any of these through-line cars which have the Stevens brake, is there any difficulty experienced in getting such cars around the curves in the streets of Baltimore? If so, what is such difficulty?

A. There is with the cars of the Philadelphia, Wilmington, and Baltimore road, caused by the rods connecting the draw levers with the brake shafts some times catching either on the king or other bolts—which causes the brakes to be put on at said curves; this sometimes causes the cars to stick on the curves; sometimes, also, when the brakes are left slack enough for the cars to get around these curves in Baltimore, they will not hold on the heavy grades on the straight tracks. We sometimes have to disconnect the brake-rods in order to get cars around these curves. We frequently do this.

21. Q. State whether any such difficulties as these are experienced with the cars in said through-lines which have the centre-lever brake?

A. There are not.

22. Q. Are there any advantages in the centre-lever brake over the Stevens brake as used on the said Philadelphia, Wilmington, and Baltimore cars, in reference to the matter of repairs? If so, what?

A. There is less repairing to be done to the centre-lever brake than to the Stevens brake.

1653 23. Q. State whether you are familiar with the construction and operation of the single brake, operating on only one truck.

A. I am.

24. Q. In your opinion, as a railroad man, if the cars of the New York and Washington through-lines had upon them single-acting brakes, would there be any more, and, if so, how many more sets of wheels required for each car in a year than there are now required in the same time on those of said cars which have the centre-lever brake?

A. It would require more sets of wheels—at least two more sets in a year than with the centre-lever brake. I mean that with the single brake three sets of wheels in all would be required to go through the year, against one set with the centre-lever brake in the year.

J. B. HILL.

Adjourned to Sept. 13th, at 10.30 a. m.

1654 WEDNESDAY, *Sept.* 13, 1871.

HUMPHREY JACKMAN, a witness duly called and sworn on behalf of complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Humphrey Jackman. Age, fifty-seven. Residence, South Bergen, New Jersey. Mechanic by occupation.

2. Q. Are you employed by any railroad company? If so, by what company?

A. I am; by the Central Railroad of New Jersey.

3. Q. In what capacity are you employed by them?

A. I am now employed at the Communipaw shops, putting up pistons, the main connections, and parallel rods, of locomotive-engines. I have several men under me.

4. Q. How long have you been in the employ of said Central Railroad of New Jersey?

A. Eleven years this fall.

5. Q. Previously to being employed by said Central Railroad were you employed by any railroad in New Hampshire? If so, by what company?

A. I was; by the Concord & Nashua R. R. Co.

6. Q. From what time to what time were you employed by the Concord & Nashua R. R. Co.?

A. I went there between 1847 and 1850, and with the exception of about six months that I was on the Vermont Valley road putting up locomotive-engines. I remained there till 1859.

7. Q. At the time you first went on to the Concord & Nashua road, what kind of brakes were in use on the passenger-cars of that road?

A. The single brake.

8. Q. At any time while you remained on said road, was there any change made in the brakes on the cars running in the passenger trains?

A. There was.

1655 9. Q. What kind of brake was put on said cars when this change was made?

A. A brake similar to the one I saw in this office yesterday—a double-connected brake.

10. Q. Do you remember any name by which said brake was called?

A. I don't positively remember the name, but I think it was called the Tanner brake.

11. Q. Do you recollect whether it had a cross-lever under the centre of the body of the car?

A. It did have.

12. Q. About how long before you left said road, in 1859, was said cross-lever brake put on?

A. I don't remember exactly, but several years before I left.

13. Q. While you were on said Concord & Nashua road, did you have opportunities to observe the effect of the car-brakes upon the car-wheels, both when the single brakes were used and when the cross-lever brakes were used; if yea, please state what your opportunities were.

A. I did. My opportunities were that, in case of any accident or overwork on the road, we were called out of the shop to assist in running the road, taking various positions on the road; and also by being intimately connected with the builder of the trucks of the cars, the man that had charge of running them, and the road-master.

14. Q. In what shop did you yourself work?

A. I had charge of putting up the engines.

15. Q. How near was the shop where you did your work to the shop where the work on, and the repairs of, said cars were done?

A. Right in one shop; the shops were all connected.

16. Q. Did you have occasion, and, if so, about how often, to see the cars when they were brought into the shop for repair, while they were being repaired, and when the wheels and brake rigging were in them?

1656 A. I had daily observation. I didn't take notice every day, but whenever they were in there I used to see them as a matter of discussion in regard to the value or merits of the two brakes.

17. Q. Which brakes do you mean by the two brakes?

A. The single and double brakes.

18. Q. After the said cross-lever brakes were put on said cars, was there any improvement with regard to the effect upon the car-wheels over the single brake?

A. There was.

19. Q. After the cross-lever brakes were put on, what was this improvement?

A. It was claimed that they saved about two-thirds—that one set with the cross-lever brake would wear as long as three sets with the single brake.

20. Q. Who claimed this?

A. It was claimed by the heads of the departments of the road; M'r Gray, the road-master; M'r Jacob Wheeler, the truck-builder and fitter of the wheels; and Charles K. West, the general superintendent of the cars and of the keeping them up.

21. Q. Did you yourself hear these parties make these claims or statements?

A. I did.

Cross-examined by M'r Whipple:

1. Cross-q. You say it was claimed that they (the cross-lever brakes) saved about two-thirds—that one set with the cross-lever brake would wear as long as three sets with the single brake. Do you know anything about this matter of the single and double brakes compared, in the matter of saving wheels, from your own knowledge?

A. I do.

2. Cross-q. Please state in what that knowledge consists.

A. From actual observation.

1657 3. Cross-q. Please state in detail what you have observed in relation to this matter of saving wheels by the use of the single and double brakes compared.

A. My own observation in seeing it didn't give so extensive knowledge as what I obtained from these heads of departments I spoke of. The single brake caused more flat places to make the wheels useless that the double-connected cross-lever brake. What I did observe was that the single brake caused flat places in the wheels that rendered it necessary to throw them away—rendered them useless. My observation was seeing the wheels rolled in, and taken off, and replaced with new ones—just as if it was right in one corner of this room and my work was in another corner of the same room, so that it was just under my eyes.

4. Cross-q. Did you ever observe any wheels being taken off having flat places in them after the application of the double brakes?

A. I did.

5. Cross-q. To what extent did the application of the double brake diminish the sliding of wheels, compared with the single brake?

A. It was claimed about three to one. It will be impossible for me to give an exact account of the difference, because the road was increasing its stock and other roads were connecting with it, so that I judge from my observation, and what the heads of departments I have spoken of said about it.

6. Cross-q. Who is Jacob Wheeler, and where does he now live?

A. He has left the shop, and, if living, is on a farm about eight miles from Concord.

7. Cross-q. Where is M'r Gray?

A. He was appointed keeper of a light-house about the beginning of the war.

8. Cross-q. Where is Charles K. West?

A. He is dead.

1658 9. Cross-q. What other names connected with that road know about the matters you have testified in relation to—the wearing of wheels with the different brakes?

A. John Kimball and Harvey Rice, both parties residing in Concord.

10. Cross-q. What kind of shoes were the brakes shod with at that time?

A. Principally leather, sometimes wood.

11. Cross-q. How are brakes now shod?

A. With iron.

12. Cross-q. What in your opinion would be the comparative wear of single brakes shod with iron, compared with double brakes shod in the same way, at the present time, upon the wheels of cars?

A. I think there would be no difference.

13. Cross-q. Would the double brake slide the wheels just as quick as the single brake with the same power applied to the windlass wheel?

A. It will not as a general thing. The power is more equally adjusted so that it will not bring it all upon one truck; it is more equally divided between all the wheels.

14. Cross-q. Is there any way to diminish the power on the single brake? If so, please state what way.

A. By not winding it up so hard the power would be less.

15. Cross-q. Is it not a rule on all railroads that brakesmen shall not wind up any brake so hard as to slide the wheels?

A. It is the rule.

16. Cross-q. Was it the rule on the Concord road when they used the single brake?

A. They did make a rule—I think a special order—on that road, while the single brake was in use.

17. Cross-q. What was the penalty if a brakeman was found to continue to disobey such order?

1659 A. I never heard of any one. I presume the penalty would be discharge. I never heard of any one being discharged for it.

18. Cross-q. Is the sliding the wheels caused by applying the brakes too hard?

A. As a general rule it is. There could be exceptional cases.

19. Cross-q. With such a rule in force do you think the wheels under the single brake would be worn out as three to one, compared with the double brake, under the same rule?

A. I should think they would, on account of the imperfection of applying the power to the single brake.

20. Cross-q. Is there any difference in the application of power to the brakes of a truck, whether it is applied to one truck by the single brake,

or to both trucks by the cross-lever brake, other than that in the latter case it is applied to both trucks simultaneously?

A. It is claimed that there is.

21. Cross-q. What is the difference?

A. From my own observation in running I would not be able to state just what the difference is; but it is claimed that in the single truck in the application of the shoes upon the wheels it strikes one pair of wheels a little before it does the other, and to produce friction enough to hold the carriages, it slides one pair of wheels while it is creating friction enough on the other pair to hold the car. With the cross-lever brake—that it holds all the wheels more equal so that the friction will hold all the wheels at once, so as to make the friction on the track equal, without sliding the wheels.

22. Cross-q. That is true, is it, with regard to the cross-lever brake?

A. It is, as far as my observation goes and means of knowledge.

23. Cross-q. What kind of brakes are used on freight-cars generally?

1660 A. I could not say. The most of the freight-cars on the Concord road were altered over from single to double brakes, the same as the passenger-cars.

24. Cross-q. What kind of brakes are used on the Central Railroad of New Jersey on the freight-cars?

A. I do not know, sir. I don't know as I ever looked at them.

25. Cross-q. What kind of brakes are used on the passenger-cars of that road?

A. They are double brakes of two patterns, I believe. My chance for observation on that road is very limited; I merely see them occasionally.

26. Cross q. What two patterns?

A. One is the cross-lever brake, and the other has two cross-levers.

27. Cross-q. So far as your observations go, is the single brake in use on freight-cars, or the double brake?

A. I see only a few freight-cars that do the local business; they have the double brake.

28. Cross-q. On what road do you speak of the "local business"?

A. The Central Railroad of New Jersey; most of the heavy business goes to Elizabethport.

29. Cross-q. Am I to understand that the freight-cars that do the local business that pass your shop, have the double brake on?

A. I couldn't say that they all have it on.

30. Cross-q. Can you say that any freight-car has it on?

A. Yes, sir.

Redirect:

1. Redirect q. What "wear" did you refer to in your twelfth (12th) cross-answer; the wear of the shoeing or covering of the brake-head, or the wear of the car-wheels?

1661 A. My answer, as I took the question, was that there was no difference in the holding power of the brakes on the wheels.

2. Redirect q. You said that when the single brakes were used on the Concord road, the brake-heads were shod principally with leather, and sometimes with wood. Was there any change made in this respect when the cross-lever brake was adopted?

A. None that I know of.

3. Redirect q. About what was the average speed of the passenger-trains on the Concord road at the time the single brakes were used there?

A. I should think from twenty to twenty-five miles per hour, including stops.

4. Redirect q. And what was the average running time?

A. I could not state exactly; I should think they would average about forty miles per hour; I am referring now to the express-trains.

HUMPHREY JACKMAN.

Humphrey Jackman recalled for complainant:

1. Q. Will you please state more fully the circumstances under which the express-trains you referred to in your deposition a little while ago, ran forty miles an hour?

A. That was not including stops; at the time, two routes from Boston, of one of which the Concord and Nashua was a part, were contesting for the British mail and the business through that way, and this led them to run at this high speed. After M'r Gilmore came in as superintendent he reduced the speed to about thirty miles per hour.

1661 2. Q. After the cross-lever brake was introduced on the Concord road, how long, if you know, did the car-wheels, on an average, last without requiring to be replaced on account of flat spots?

A. I could not give an answer to that; I only know the difference from my own observation, and that there was a great difference.

(Witness here says he desires to state, in reference to what he has testified above, in relation to double brakes on the local freight-cars, that he is unable to say that the freight-cars on which he saw the double brakes belonged to the Central Railroad of New Jersey.)

HUMPHREY JACKMAN.

Patrick S. Devlan, a witness duly called and sworn on behalf of complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Patrick S. Devlan; age fifty-one; residence Jersey City; my trade is that of machinist.

2. Q. Were you ever in the employ of any railroad company; if so, of what company or companies?

A. I was first employed by the Tamaqua Railroad Company; next by the Reading Railroad Company; next the Harrisburgh and Lancaster; next the Cumberland Valley; next the Central Railroad of New Jersey, which was the last.

3. Q. In what capacity or department were you employed on these roads?

A. On the Tamaqua as engineer; on the Reading in the department of construction; on the Harrisburgh and Lancaster as engineer; on the Cumberland Valley as engineer; on the Central Railroad of New Jersey in the repairs of engines.

1663 4. Q. About how many years in all were you practically employed on railroads?

A. Since 1835.

5. Q. About when did you leave the employ of the Central Railroad of New Jersey, which you say was the last road you were on?

A. In 1862.

6. Q. While you were engaged on any of these railroads, did you become familiar with the construction and operation of what is called the single brake, acting on only one truck of the car?

A. Yes, sir.

7. Q. Was there at any time, upon any of these roads, a change made

in the brakes which were applied to the cars running in the passenger trains; if so, what was the change?

A. There was—from the single to the double-acting brake.

8. Q. What was the form or name of the double-acting brake to which the single brake was changed?

A. I don't know that I can state the name. We always called it the double-acting brake.

9. Q. State whether it had a cross lever under the centre of the body of the car.

A. It had.

10. Q. State whether, while you saw the single brake in use upon the cars you have mentioned, you had opportunities of seeing what were the effects of it upon the wear of the wheels of the car.

A. I had opportunities. I have frequently rode on the cars and seen the single brake block the wheels instantly, when it was applied. It required a man to be skilled very thoroughly as a brakeman to apply the brakes properly with the single brake. I have seen a pair of wheels spoiled going down one grade with the single brake on the Reading Railroad.

1664 11. Q. State whether you had opportunities of seeing the trucks and car-wheels when sent into the shops for repairs, when the single brake was in use on the roads you have mentioned.

A. I had.

12. Q. State whether you had opportunities of seeing the effect on the car-wheels after the cross-lever double-acting brake was introduced on any of the roads you have mentioned.

A. I had. The turning of the axles, the boring of the wheels, and the putting the wheels on, came directly under my charge, and I had every chance to see them.

13. Q. Was there any difference in the effect produced on the car-wheels after the cross-lever brake was introduced, as compared with the single brake; if so, what was the difference?

A. There was a difference. We always considered there was a saving of from three to four sets of wheels a year with the cross-lever brake over the single brake.

14. Q. Taking the average of passenger trains on any railroads with which you were familiar, say in the year 1862, and suppose that instead of double-acting brakes on such trains single-acting brakes had been used; what, in your judgment, as a practical railroad man, would have been the results as to the power of the brakemen over the trains, and as to the wearing of the wheels?

A. They would have to have at least double the number of men; there would be more liability to accident; they couldn't hold the train with one-tenth part of the power that they could with the double-acting brake; there would be an extra wear on the brass journal bearings. I have put in two sets of brasses in a month with the single brake against one set in three months with the double-acting brake; and there would be a wear of at least three times as many wheels with the single brake as with the double brake.

1665 15. Q. Do you know what these brass journal bearings cost per set; if so, how much?

A. They will average eight pounds each. The least I have ever known them to sell for is thirty-five cents to thirty-eight cents per pound. There are eight of these brasses to a car.

16. Q. When the brasses have to be replaced, what are they worth as old brass?

A. Half price.

17. Q. Is there any difference in the effect produced upon the railroad track by the use of wheels acted upon by the single brake, and wheels acted upon by the cross-lever double brake?

Q. There always is a lamination of the track or rail where there is a sliding of the wheels. I should think there was a difference in favor of the double brake, on account of the wheels not sliding.

18. Q. Are you able to state whether this difference is considerable or not?

A. I don't think I can say as to the exact extent. I think the difference is considerable.

19. Q. About how long, on the average, did the car-wheels last before requiring to be replaced, on the roads you have mentioned, after the cross-lever double-acting brake was introduced?

A. The average was between two and three years.

(Cross-examination waived.)

PATRICK S. DEVLAN.

Adjourned to Thursday, Sept. 14th, at 10.30 a. m.

1666 THURSDAY, *Sept.* 14, 1871.

PATRICK S. DEVLAN, recalled on part of complainant:

20. Q. In answering the question put to you yesterday in respect to the average wear of the car-wheels after the cross-lever brake was introduced, what wheels were you referring to, as an average?

A. I meant the best wheels on the Reading road.

21. Q. Will you now state what, according to your observation, was the average wear of car-wheels in passenger trains, when the double-acting brake was used, taking the average of all the wheels in the market?

A. About twelve months.

22. Q. Will you please read over your answer to the 13th question put to you yesterday, and state how you meant to be understood in that answer?

A. I meant to convey that there would be a saving of from two to three sets in the course of a year; that is, I mean, taking the set that was in the car, it would take three to four sets to go through the year with the single brake, against one set in the year with the cross-lever brake.

Cross-examined by M'r Whipple:

1. Cross-q. Are you familiar with the construction and operation of the cross-lever double-acting brake?

A. I am.

2. Cross-q. Please explain its construction, and wherein it differs from the single brake, as applied to the trucks of a car.

A. I don't know that I can explain it any better than by saying that the brake-blocks are all connected so as to be operated by one man, acting upon all the eight wheels instead of four.

1667 3. Cross-q. Wherein does the mechanism of the brake, so far as the trucks are concerned, when the single brake is used, differ, compared with the same mechanism when the brakes are connected?

A. The single action is a direct action, and we call the double acting a compound connection. I don't know that there is any difference in the construction of the brake in the trucks, except in the hanging of the brakes.

4. Cross-q. Wherein do they differ in the hanging?

A. There is a vast difference in the single acting brake in the mode of applying it.

5. Cross-q. Please state that vast difference—in what it consists?

A. One way of hanging it was a cross between the two wheels, to act on the brake blocks.

6. Cross-q. What do you mean by "cross"?

A. I think I can hardly show but by a diagram.

7. Cross-q. What is the ordinary, common, method of applying brakes to a single truck? Please explain the parts that make up a single brake, as you say you are familiar with the construction of brakes.

A. The ordinary, common, method now is a frame hung in front of and behind the wheels, acted on directly by the lever—the two connected together; that is what makes up a single brake, acted on directly by the lever. There are different modes of applying the lever.

8. Cross-q. What more is the cross-lever brake than the union of two single brakes?

A. Well, there is a combination of leverage there that you don't get in the two single brakes; couldn't get it.

9. Cross-q. Is or is not the mechanism of the trucks, so far as the brakes is concerned, the same, whether used as a single or double brake?

A. That would be a hard question to answer direct, there have been so many improvements made in the construction of trucks. There is as much difference in the construction of trucks as there is in locomotives.

1668 10. Cross-q. Then you don't know whether there is any difference or not in the mechanism of the trucks, so far as the brakes are concerned?

A. Not at the present time.

11. Cross-q. What regulation, if any, was had on the Reading road, in regard to brakemen sliding wheels?

A. As a general rule, they were discharged if they were known to do it.

12. Cross-q. Did this regulation apply to brakemen employed on both freight and passenger trains?

A. As a general thing it did.

13. Cross-q. Did this regulation have the effect to prevent the brakemen from sliding the wheels?

A. I don't know that it did.

14. Cross-q. Did the brakemen slide the wheels after the double brake was applied?

A. I don't know of any instance, except with the Leahey brake, which was so severe that it would lock the whole eight wheels.

15. Cross-q. Was this Leahey brake operated by brakemen?

A. No, sir; by the engine bumper.

16. Cross-q. If too much power be applied to a brake, is there any way, within your knowledge, to diminish that power so as to prevent brakemen sliding the wheels?

A. It rests with brakemen entirely. Hence a green hand never makes a good brakeman.

17. Cross-q. If the wheel attached to the standard by which the brakeman applies the power to the brakes is made smaller than the usual size, what effect will such diminution of size have?

A. If a practical brakeman, he will exert more power in turning the wheel. A practical brakeman can tell to a fraction what power is required to prevent sliding the wheels, as a general thing.

18. Cross-q. Did they have practical brakemen on the Reading road when you were there?

A. Part of them were.

1669 19. Cross-q. What kind of brakes were used on the freight cars of the Reading road when you were there?

A. The single and double acting brakes.

20. Cross-q. On such cars as the single brake was used, was the destruction of wheels by sliding as three to one, compared with the wheels on the cars on which the double brake was used?

A. It was generally considered so by the car-builders. It may have been less on the freight cars; there was a vast difference.

21. Cross-q. What do you know of the matter of your own knowledge?

A. I furnished the wheels and axles; they came under my supervision.

22. Cross-q. Did you take account of the wheels after they were used under the cars, so that you are prepared to say how long they wore, both under the single and the double brake?

A. I furnished the wheels and axles, and had to take the word of the car-builder as to the difference in the wear. It was the general talk that that was the average difference in the wear, by the car-builders. I did not keep an account of the wheels after they were used. I kept an account of the wheels that went out.

23. Cross-q. What car-builder on the Reading road did your hear say there was this difference of three to one in the wear of wheels, when used under the single brakes, compared to the same use under the double brakes?

A. Samuel Spotts.

24. Cross-q. What other person or persons did you hear make these statements?

A. The master machinist of the road, Louis Kirk.

25. Cross-q. Where is he?

A. He is dead.

26. Cross-q. Any other persons?

A. It was the general remark about the place.

1670 27. Cross-q. In view of the fact that the cross-lever brake is but a connection of two single brakes, how do you account for your statement that the difference between the single brake and double brake in sliding wheels, and thereby spoiling them, is three to one?

(Question objected to, because the statement in it that the cross-lever brake is but a connection of two single brakes is incorrect.)

A. I don't know how I can account for it otherwise further than that a man can lock two or four wheels, and can't regulate his power so well on the wheel or lever as he can with the double-action brake. It is almost an instantaneous action with the single brake; the double brake is more gradual.

28. Cross-q. Could a brake wheel be put upon the standard upon which the chain winds of such diameter that the brakeman could not slide the wheels by the brakes of a single brake?

A. Certainly, you could put a wheel on two inches in diameter, and you could not turn it, or more than turn it.

29. Cross-q. Could you increase the power the brakeman would have over the wheels by increasing the diameter of the brake-wheel?

A. Certainly; the larger the more leverage he would have.

PATRICK S. DEVLAN.

Luke F. Tronson, being duly called and sworn on the part of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Luke F. Tronson; age, fifty-four years; residence, Newark, New Jersey; occupation, machinist.

1671 2. Q. Are you in the employ of any railroad company? If so, what company?

A. Yes, sir; the Morris and Essex division of the Delaware, Lackawanna and Western R. R.

3. Q. How long have you been employed by the Morris and Essex Company?

A. Thirty-one years and upwards.

4. Q. Are you familiar with what is called the single-acting brake for cars?

A. Yes, sir; somewhat acquainted with them.

5. Q. Was said single brake used upon said Morris and Essex R. R., on cars running in passenger trains, at any time since you have been employed there?

A. Yes, sir.

6. Q. State from about what time to what time such brakes were used upon such cars.

A. From the year 1840 to, I think, in the neighborhood of 1852—1852 or 1853.

7. Q. At this time—1852 or '53—was there any change made in the brake used on the cars running in the passenger trains on that road?

A. Yes, sir.

8. Q. What was that change?

A. They put what we called the centre-lever brake on—the cross-lever brake.

9. Q. How near was the shop where you worked on this road at this time to the shop where the work on and the repairing of the cars was done?

A. One shop adjoined the other.

10. Q. Do you know what was the general opinion of the men in charge of the cars running in the passenger trains on that road in regard to the effect of this change from the single brake to the cross-lever brake? If so, what was it?

A. They liked the double brake better than the single brake. This is what the men who used the brakes stated. The men who had 1672 charge of the cars preferred the cross-lever brake—for one thing, because of the greater durability of the wheels.

11. Q. State, if you know, what was the general opinion among these men who had charge of the cars as to how much longer the car-wheels lasted with the cross-lever brake than they did with the single brake.

A. The man who was foreman of the car department at that time—William Pierson—told me that he thought he could save two sets of wheels out of three. What he meant by that was that it would take three sets of wheels with the single brake where one set would last as long with the cross-lever brake.

(Answer objected to as hearsay.)

12. Q. What I want to get at is not what any particular man said, but what the general opinion on this matter was among the men who had charge of the cars.

A. I hadn't conversed with any but Mr Pierson on this particular subject.

Cross-examined by M'r Whipple:

1. Cross-q. Do you know anything as to the matter testified to in relation to the comparative merits of the single and double brakes, in the matter of sliding wheels, of your own personal knowledge?

A. Not of my own personal knowledge; but I can tell you just what they told me about it.

LUKE F. TRONSON.

Adjourned to Friday, Sept. 15, at 11 a. m.

1673 FRIDAY, *September* 15*th*, 1871.

SAMUEL L. MOORE, being duly called and sworn on the part of complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Samuel L. Moore; age, sixty-eight years; residence, Elizabethport, Union County, New Jersey; occupation, foundry machinist.

2. Q. Have you ever been employed upon any railroad? If so, upon what railroad?

A. I have—three or four—the Philadelphia and Trenton R. R., the New Jersey Railroad and Transportation Company, the Corning and Blossburg road, and the last road was the Central Railroad of New Jersey.

3. Q. Are you familiar with the construction of what is called the "single brake" for railroad cars?

A. Yes, sir. I have seen almost all kinds of brakes ever invented up to the last ten or twelve years.

4. Q. At any time while you were employed upon any of the roads you have mentioned was the single brake used upon such roads?

A. Yes, sir.

5. Q. Upon what kind of cars was it used on such roads?

A. First upon four-wheeled cars, and afterwards upon eight-wheeled cars.

6. Q. In what kind of trains did these eight-wheeled cars run?

A. In all kinds—passenger and freight.

7. Q. At any time while you were engaged in railroading was there any change made in the kind of brakes used on the cars running in passenger trains?

A. Yes; they threw away the single brake and put on the double brake—the Hodge, Stevens, and Tanner; they all came up about the same time; I can't tell which we put on first.

1674 8. Q. After the double brake—say the Tanner brake—was put on these cars, was there any improvement or saving produced from the use of it?

A. Yes; I think there was.

9 Q. What was this improvement or saving?

A. Why, in the first place, they were more sure—stopped the train quicker; in the next place, they were easier kept in repair; in the next, the wheels lasted from one-half to two-thirds longer.

10. Q. Taking the wheels under an eight-wheeled car as a set, how many sets, in your judgment, would be required with the single brake to last through the same time that one set with the Tanner brake would last through?

(Objected to.)

A. Well, it would take from two and a half to three sets.

Cross-examined by M'r Whipple:

1. Cross-q. You say, in your answer to the seventh interrogatory, that they "threw away the single brake." Do you mean that they dispensed with the use of it altogether on all their cars, both freight and passenger, and substituted therefor the double brake?

A. No, I don't; but I mean to say that when the old brake wore out and had to be renewed, or we got new cars, we threw away the old brake and put on the new one. I saw a car yesterday that still had the old single brake on it.

2. Cross-q. How was the single brake constructed that you say was thrown away?

A. Well, I don't know; there was about as many ways of construction as there was cars. The general way on the passenger cars was to have a rock-shaft between the truck-wheels, and a toggle-joint from the rock-shaft to the brake-block, where the wheels were far apart. Some had only a toe on the rock-shaft.

1675 3. Cross-q. Was this kind of brake thrown entirely away when the Tanner brake was substituted?

A. It was; the single brake was entirely abandoned when they put on the double brake—on all good cars.

4. Cross-q. Please describe the mechanism of the Tanner brake, as applied to the trucks.

A. The Tanner brake has eight friction-blocks connected by rods to the windlass-staff at either end of the car, so that from either end the brakemen can apply them all to the wheels of the car. As to the mechanism in the trucks, there is one lever in each truck to operate the brakes in the truck. I think that is the Tanner patent.

5. Cross q. Was not one lever used in the truck, with proper connections for operating the brake-blocks, in use before the date of the Tanner patent?

A. Yes, I think there was.

6. Cross-q. Then how do you make it out that such connection is the Tanner patent?

(Objected to, as the *the* witness has not made any such statement.)

A. Tanner, I suppose, don't patent the lever, but the combination of levers; else his patent wouldn't be good for anything. The old-fashioned brake only broke on one truck.

7. Cross-q. What is the Tanner patent but a combination of the lever in each truck, as used in the single brake, with each other, by means of a cross-lever and the windlasses of the car? If it is not this, please state what it is.

A. The difference is that the cross lever connects the mechanism in both trucks to each other so that they can be operated from both ends of the car; and if one connection breaks from the brake-staff, both brakes can be operated from the other end of the car.

1676 8. Cross-q. Why is it, as you stated, that wheels will last longer when used under the double brake than when used under the single brake?

A. Because they don't slide them so much.

9. Cross-q. Are not the wheels slid when used under the double brake?

A. They are sometimes, but nothing like they are under the single.

10. Cross-q. By diminishing the diameter of the wheel on the windlass-staff, cannot you prevent sliding the wheels either in the single brake or the double brake?

A. Of course, if you are a mind to take the power off, you can't slide the wheels. Then you can't brake up. You might do as they did in the old times, run cars without any brakes; then you couldn't slide the wheels.

11. Cross-q. When, in your judgment, do brakes hold the best, when the wheels are sliding or when rolling, provided the power in either case has been applied efficiently?

A. They hold best when they are rolling.

12. Cross-q. Then may not the diameter of the windlass-wheel be so proportioned to the braking to be done, both as respects the single and double brakes, as to do effectual braking without sliding wheels in either case?

A. No. The reason is no man can pretend to say that you can retard a railroad car as much with four wheels as you can with eight wheels. I understand your question, but it cannot be done.

13. Cross q. Why cannot be done?

A. For the reason that the power it will take to slide a wheel one day will not do it another; you can't do it because you cannot regulate the power; it will take more power one day than it will another; it will take more power to slide the wheels under a heavy loaded car than it will under a light one.

1677 14. Cross-q. Assume that it requires a windlass-wheel thirteen inches in diameter to brake the two trucks of a car by means of the double brake, under the various circumstances that occur, may not a smaller wheel do the same work as effectually, without sliding, on one truck, as a larger wheel does on two trucks, and this without sliding the wheels in either case?

A. Well, you might put the same power with a small wheel by exerting more force on the windlass-wheel.

(The question being read again to the witness, he answers: No; you cannot.)

15. Cross-q. Why not?

A. Because a man can slide the whole eight wheels by putting power enough on; he can't do any more on four wheels than to slide them, only it won't take quite so much physical strength.

16. Cross-q. Can the size of the windlass-wheel be so small in both cases, that is when applied to a single brake or a double brake, as to prevent sliding wheels in either case?

A. Why, certainly it can be. You can take it off altogether and then you won't brake any.

17. Cross-q. Do you think there would be any sliding wheels by the use of the single brake with a windlass-wheel six or eight inches in diameter?

A. It would be altogether owing to the length of the fulcrum and the length of the levers. If you had your fulcrum short enough, you could slide your wheels then; if your fulcrum is short enough, it would take very little power on the windlass-wheel to slide the wheels of the car.

18. Cross-q. May not the size of the windlass-wheel and the proportions of the lever be such as to prevent sliding wheels in a single brake, ordinarily?

A. Certainly it can. You can make it so it can't slide the wheels, but the next thing is whether that would be sufficient to stop the car.

1678 19. Cross-q. Is the car best controlled or retarded when the wheels are sliding on the rail under the brakes?

A. No.

Redirect:

1. Redirect q. State whether, in the case supposed in the eighteenth cross-interrogatory, if the brakeman should apply strength enough he could slide the wheels.

A. Certainly he could.

2. Redirect q. State whether at the time the Tanner brake was introduced on the roads you have spoken of, the various matters you have been asked about—in respect to the effect of increasing or diminishing the size of the windlass-wheel, and altering the fulcrum and the length of the levers—were known to railroad men.

A. I suppose so. Men were not fools forty years ago any more than they are now. They knew something about the power of levers.

3. Redirect q. Did you yourself know about the various matters referred to at the time inquired about?

A. Of course I did. I was over thirty years old when I began railroading.

Recross:

20. Cross q. Was it allowable among railroad managers that brakemen should use their entire physical force upon the brake windlasses when applying the brakes?

A. No. It was generally their orders not to slide the wheels.

21. Cross-q. What penalty, if any, was attached to such misdemeanor?

1679 A. I don't know of any. If there had been they wouldn't have had many brakemen.

22. Cross-q. Was the kind of single brake in use before the double brake called the rock-shaft brake, applied by a foot-lever?

A. I don't know as it was called the rock-shaft brake, but it had a rock-shaft in it, and a lever that come up and you put your foot on it.

23. Cross-q. Am I to understand that this was the single brake in general use on roads before the double brake was introduced—that is, so far as your knowledge extends?

A. It was the brake that was in universal use say from 1840 to 1845, or 1846 or 1848, or to the time when the lever single brake was introduced.

24. Cross-q. To what extent was the lever-brake adopted thereafter?

A. Universally, generally, on the good roads—easier got up and easier kept in repair.

25. Cross-q. With which was the brakeman most liable to slide the wheels, the rock-shaft brake or the lever-brake?

A. The rock-shaft brake, if it was in good order.

26. Cross q. Is your comparison of the saving in wheels between the double brake and the lever-brake, or as between the rock-shaft brake and the double brake?

A. I don't know, but I think more likely between the rock-shaft brake and the double brake, because the rock-shaft brake went out of use some time before we got the double brake. I am satisfied the old rock-shaft brake used to grind up the wheels a great deal faster than any other brake.

SAM'L L. MOORE.

1680 **John P. Van Doren**, recalled on part of complainant, testified as follows:

1. Q. Have you ever been in the employ of the New Jersey Railroad

and Transportation Company? If so, in about what year did you first enter their employ?

A. Something like sixteen years or seventeen years ago.

2. Q. How long did you remain in their employ?

A. Ever since; am partly under their control now.

3. Q. Were there any double-acting brakes in use on that road at or after the time you first went into their employment?

A. I remember well when the order came out to put the double brake on when we overhauled the cars.

4. Q. Previous to their putting on these double brakes what kind of brakes had they used on the cars running in their passenger trains?

A. A brake that broke only on one truck—four wheels, with a single lever on the end of the truck toward the platform.

5. Q. What name, if any, to your knowledge, was the double brake they put on in the place of this single brake called?

A. I never paid much attention to the names of these brakes. It had a center lever.

6. Q. After they introduced this center-lever brake was there any better result produced by the use of it, as compared with the old single brake?

A. There was; a man could brake both trucks, where before he could brake only one.

7. Q. Was there any saving produced by it over the single brake? If so, in what respect?

A. It saved the wheels a great deal—the sliding of the wheels.

8. Q. Will you please state about how much longer the wheels lasted with the centre-lever brake than they did with the single brake?

1681 A. I think they lasted full as long again with the centre-lever brake as they did with the brake on one truck.

9. Q. Assuming that, with the centre-lever brake, one set of wheels upon an eight-wheel car would last a year, how many sets of wheels would be required to last the same time with the single brake? I am referring to passenger trains, and to wheels on the average.

A. It would take from two to three sets for the year.

10. Q. Will you please state what have been your opportunities of knowing about the wear of car-wheels since you have been in the employ of the New Jersey road?

A. I have most of the time since I have been in their employ had charge of the men engaged in taking the wheels out and putting them in, and it was done according to my instructions.

Cross-examined by M'r Whipple:

1. Cross q. When you made the application of the centre-lever brake to the cars of your road did you make any essential change in the mechanism of the brakes as applied to the trucks?

A. No, sir.

2. Cross-q. What did you do in order to convert the two single brakes of a car into a double brake?

A. I took and turned the truck so as to bring the lever, or that end of the truck, toward the center of the car, so that I could connect the rods to the centre lever under the centre of the car.

3. Cross-q. Any further connections than with the centre lever in order to complete the brake?

A. We have to connect the brake-shafts to the centre lever.

1682 4. Cross-q. Have you had anything to do with taking out wheels under freight cars? If so, how long a time did such wheels last, as a general rule, from the time they were first put in?

A. I have; and where there were no brakes on them I have known them to last six or seven years. The average of the wheels under brakes was about six months.

Redirect:

1. Redirect q. What was the average speed of the freight trains, the wheels of which lasted on an average six months?

A. About fifteen miles an hour; fifteen to twenty.

2. Redirect q. In stopping freight trains and passenger trains by brakes, in which are the brakes kept on the wheels longest?

A. In the freight trains.

JOHN P. VAN DOREN.

Adjourned to Tuesday morning, September 19th, at 10 o'clock.

Further adjourned to Tuesday morning, Sept. 26th, at 10.30 a. m.

TUESDAY, *Sept. 26th*, 1871.

HUMPHREY JACKMAN recalled on behalf of the complainant.

1. Q. While you were on the Concord & Nashua road did you see in use any other kind of double-acting brake than the centre cross-
1683 lever brake you have referred to in your previous examination?

A. I did.

2. Q. What was such other kind of double-acting brake?

A. It was what was called the two chains, or double-lever brake.

3. Q. Whereabouts in the car were the double-levers?

A. Under the car, over the trucks. Sometimes they are placed under the trucks.

4. Q. State how they were placed with reference to the body of the car.

A. I don't know as I could give you an exact answer. The two chains passed from one truck to the other on each side of the car. They are so connected wherever they are placed that they connect on the lever that has a fulcrum that is connected to the wheel or brake-wheel. I wish to state further that they are a brake I never adjusted or repaired. My knowledge of them is simply my observation—seeing them on the road.

5. Q. State whether these double-levers over the trucks, in this brake, were or were not cross levers.

A. I shouldn't be willing to say that they would be defined as cross-levers. They constituted a double-acting brake.

6. Q. I mean, did or did not these double-levers over the truck extend crosswise of the car?

A. They did. These levers leaned over the trucks, and connected with a lever running parallel with the car.

7. Q. You say you never adjusted or repaired this kind of double-acting brake on said railroad. Will you state here what kind of double-acting brake it was which you did adjust and repair there?

A. It was a brake with a centre or cross-beam running crosswise of the car at the centre of the car. One end of the cross-beam was attached to the brake by a chain or rod.

1684 8. Q. How was the other end of the cross-beam connected?

A. The other end was connected by a chain or rod to each one of the truck-brakes.

9. Q. State, if you recollect, any name by which this last mentioned brake was called?

A. I could not. I had forgotten the names of both brakes, it was so long since, till I heard them mentioned here.

10. Q. State whether this center cross-beam or cross-lever brake is the brake referred to by you in your previous examination here.

A. I should wish to make a full statement as regards that—as to my knowledge of it. My knowledge, the most of it, was from the merits of double-acting brakes on the wheels of the trucks. In the discussions the merits of the different machines was not brought into discussion, but the value of the brakes over the old single brake. My knowledge of the brakes was derived from argument with experienced men who were connected with the working of them.

11. Q. Question repeated.

A. It was.

12. Q. You spoke of it in your previous examination here as used on the Concord & Nashua road. Please state what knowledge you have as to whose cars it was that it was used on over the Concord & Nashua road.

A. There were nine roads that run their cars in there, and from them, being called out at different times when they had gatherings there in Concord, requiring more help than was usually employed, was where I got my information in regard to the different brakes—my knowledge. As to whose cars it was used on, I shouldn't wish to be understood as saying positively what roads the cross-lever brake was adopted on, or what cars. The cars of these different roads—these nine roads—
1685 ran over the Concord & Nashua road. I do not mean that the cars of all these roads had the cross lever brake; some of them did have.

13. Q. State whether these cars of these other roads which had this centre cross-lever brake ran over the Concord & Nashua road at the time you were on that road.

A. They did.

14. Q. Now, will you please repeat how it was that you came to see these said brakes on cars which had run over said Concord & Nashua road?

A. By being called out what we called privileged days—days of excitement—when there were more cars used than generally. I was called out to keep cars and engines in repair, in working order for the day.

15. Q. State whether or not you were so called out for the same purpose on other days than these "privileged days."

A. I have been in case of accidents and trying my engines.

16. Q. Now, please state all the means, both from your own personal observation or otherwise, which you had for making the statements contained in your previous examination here respecting the comparative wear of the wheels with the single brake and with the cross-lever brake.

A. My means were, coming in contact and being connected with men directly connected with the different branches of work bearing on the wear and durability of the wheels, and by being called out at these "privileged days" to keep the engines and cars in running order, and observing the effects on the wheels and machinery—all the running gear.

17. Q. In your previous examination here you stated that there was no difference in the holding power on the car-wheels of single brakes shod with iron and double brakes shod with iron. Please state more fully what you mean by this.

1686 A. I wish to convey the idea that it would have the same effect were they, both kinds, shod with leather or wood; that it would not make any difference.

18. Q. State whether or not you mean that as to the holding power on the wheels it would make no difference whether the single brakes or the cross-lever brakes were both shod with iron or were both shod with wood or leather.

A. I don't think it would. That is what I mean.

19. Q. State what difference, if any, would be produced as to the wearing of the wheels in the ratio of three to one by the single-acting brake in comparison with the double-acting brake, as stated by you in your previous examination, if both the single and double-acting brakes were shod with iron or both were shod with wood or leather.

A. I don't think it would make any difference.

20. Q. Please state whether, since you were examined here the other day, you have looked at any of the local freight-cars running on the Central Railroad of New Jersey.

A. I have.

21. Q. Did you see what kind of brakes any of the said local freight-cars had; if so, state whether they were single or double-acting brakes?

A. I did. They were double-acting.

22. Q. State, if you noticed, what railroad company's name was on said local freight-cars.

A. Central Railroad of New Jersey.

23. Q. Please state if you have ever noticed whether there is any difference between the effect of single-acting brakes and double-acting brakes in regard to the wear of the journal-brasses?

A. I have.

24. Q. Upon what kind of railroad carriages have you noticed this effect more particularly?

A. On the engine-tenders.

25. Q. With which kind of brake, the single-acting or the double-acting, is the wear of the journal-brasses the least?

A. The double-acting.

1687 26. Q. State about what, according to your observation, is the ratio of difference in this wear of the journal-brasses in favor of the double-acting brake, as compared with the single-acting brake.

A. I should say about one-half; the saving of the double-acting brake over the single in the wear of the brasses is two to one, to the best of my knowledge.

27. Q. Please state what have been your opportunities for obtaining knowledge on this subject.

A. I have direct charge of the repairs and building of the trucks and tenders. Up to within one year, for the last twenty or twenty-five years, that has been my opportunity of knowing.

28. Q. State what kind of brakes, whether single-acting or double-acting have been used on the locomotive tenders which have been under your charge for the said twenty or twenty-five years.

A. Single-acting brakes up to within ten years, or somewhere near that, and both since that time—single and double.

29. Q. Upon what railroads have said tenders, some having single and some double brakes, been under your charge during said period?

A The Central Railroad of New Jersey—for the last ten or eleven years.

30. Q. What kind of brakes, whether single or double acting, were in use on the tenders under your charge on the Concord & Nashua road and its connections?

A. The single brake.

Cross-examined:

1. Cross-q. What kind of double brakes are used on the tenders of the Central Railroad of New Jersey?

A. The single cross-lever.

2. Cross-q. What first called your attention to the difference, if
1688 any, between the wearing of the brasses in the trucks in which
the single brake is used, compared with those in which the double
brake is used?

A. I was connected in 1861 with the "patent antifriction metal box" owned by a man by the name of Devlan, P. S. Devlan, and I gave that my strict attention for the space of three or four years, to ascertain its value in all places where we could have a bearing, giving it its trial in the hardest places. There is where I found the wear that the double-connected lever had over the single.

3. Cross-q. Did you keep an accurate account of the wear of the brasses when used under the single brake, and the same account of like brasses when used under the double brake, as to the number of miles run and time run in each case?

A. We did not. We kept an accurate account of the wear and the mileage of the engines, but not with regard to keeping an account of the wear of the boxes, but it led to the finding out of the difference in the wear of the brasses between the single brake and the double brake.

4. Cross-q. Do you wish to be understood that the brasses used on the tenders of the engines of the Central Railroad of New Jersey, the trucks of which are controlled by the double brake, wear as long again as the same brasses would on the truck of the same engine where only the single brake is used?

A. I do. That is my judgment.

5. Cross-q. How much longer, if any, do the brasses on the truck of the tender that is not under the brakes wear compared with the truck in the same tender that is under the brakes?

A. The difference is about ninety thousand miles to forty thousand miles. Ninety thousand miles to the box on the truck which has no brakes to forty thousand to the box on the truck which has the brakes.

6. Cross-q. What is the difference in wear in miles as between the double brake and the single brake on tenders, in the matter of the wear-
ing of brasses?
1689 A. The brasses in the trucks with the double brake will run
about seventy-five thousand miles, and brasses in trucks with
the single brake will run about forty thousand miles.

7. Cross-q. How do you account for this difference in the wearing of brasses under the single and double brakes compared?

A. I account for the extreme wear of the single brake that it has the same work to do, the same power to hold, that the four sett does with the double acting. With the single-acting brake you wind up so hard that it creates a "chatter" or jumping motion of the wheels—sometimes will stop one while the other seems to jump along with an uneven motion. The double brake being all wound up will create the friction without being wound up so hard as to make an uneven motion.

8. Cross-q. Is not one of the wheels slid in one or both trucks while the others roll, even when the double brake is used on the tenders?

A. Yes, sir; they can be, and they do frequently slip.

9. Cross-q. When such is the case will it not have the same effect on the brasses?

A. It would.

10. Cross-q. Cannot the size of the windlass-wheel be so diminished, or the size of the part upon which the chain is wound so enlarged, that no more power could be put on one truck when the single brake is applied, than would be put on the same truck when the double brake is applied?

A. Certainly.

11. Cross-q. Would or not this diminution of the size of the windlass-wheel, or the increasing of the mandrel upon which the chain is wound, apply equally well to single brakes on cars as to single brakes on tenders?

A. It would.

1690 Redirect:

31. Q. Suppose the power exerted by a single-acting brake was reduced in the manner just inquired about, so that it was made to exert no more power on its truck than is exerted on one truck of a car which has the double-acting brake, would or not, in your judgment, such reduced power of the single brake be enough to stop the car efficiently?

A. It would not.

32. Q. How did you find out the difference in miles which you have stated the journal-brasses would run with the cross-lever brake as compared with the single brake?

A. I found out by keeping accurate accounts, in testing different kinds of boxes to ascertain their merits as wearing material.

33. Q. You have stated in your cross-examination that even when the double brakes are used on tenders, the wheels can be slipped and do frequently slip; with which kind of brake, the single brake or the cross-lever brake, do they slip the most often?

A. The single brake.

34. Q. What is this due to?

A. Sometimes it is due to irregular hanging, but as a general thing, to having too much power put on the brake-wheel.

35. Q. State whether or not, as a general thing, there is any more power applied to the single brake on tenders than is considered necessary by the person using the brake to do efficient braking?

A. No.

36. Q. State whether or not your last three answers apply equally well to passenger and other cars as to locomotive tenders.

A. I don't see why they would not; I should think they would.

1691 Recross:

12. Cross-q. To produce efficient braking of a car or tender, is it necessary that power enough shall be applied to slip the wheels?

A. It is not.

13. Cross-q. Then isn't there too much power applied when the wheels are slipped?

A. If there is no irregularity in the hanging there is.

34. Cross-q. How can the power be diminished so as not to slip the wheels, either with the double or the single brake?

A. By altering the fulcrum; enlarging the post on which the chain winds, or diminishing the wheel by which the brakes are wound up.

Redirect resumed:

37. Q. Was the effect of thus altering the fulcrum known to railroad men in the days when single brakes were used on cars, before any double-acting brakes were introduced?

A. It was.

38. Q. Did you ever see a single-acting brake, which had its fulcrum so altered from the ordinary mode of arranging such brakes that the power applied could not be made to slide the wheels?

A. I never did.

39. Q. If a single brake was so arranged that it never could apply any more power than as just inquired about, would or not, in your judgment, such a brake be capable of doing efficient braking in the present days of railroading?

A. I don't think it would.

Recross resumed:

15. Cross-q. Suppose the double brake was so arranged as in the last question, would it do efficient braking; that is, if it could not slide the wheels?

1692 A. It would do double the work that the single one would. I think it would do efficient braking under the circumstances inquired about.

16. Cross-q. Are the wheels slipped when used under the double brake?

A. They are sometimes.

17. Cross-q. Are they not often?

A. I suppose, of course, they are.

18. Cross-q. Then, in your judgment, it is necessary to have power enough to slip the wheels; is it or not to do efficient braking, whether the single or double brake is used?

A. It is not necessary; they never should be slipped.

Redirect resumed:

40. Q. Compared with the frequency with which the wheels are slipped when the single brake is used, would you say that they are slipped often with the double brake?

A. I would not in comparison.

Recross resumed:

19. Cross-q. Was it or not thought by those that had to do with brakes, when the single brake was used and before the double brake was introduced, that the most efficient braking was done when the wheels were slid, or "chocked," as it was called?

A. I presume it was considered so by the ignorant, but it was not among mechanics.

20. Cross-q. What was the resort of mechanics to prevent ignorant brakemen sliding the wheels?

A. A discharge of the brakemen. That was the penalty.

1693 21. Cross-q. Did you ever know of a mechanic diminishing the size of the windlass wheels by which the brakes are applied to prevent the brakemen sliding the wheels?

A. I don't know that I ever did.

22. Cross-q. Did you know of mechanics ever doing anything to prevent brakemen sliding wheels?

A. That has been a great study among mechanics; to arrange the leverage to equalize the power to the average strength of the men employed.

Redirect resumed:

41. Q. Which equalizes this power the most nearly; the single-acting brake or the cross-lever double brake?

A. The cross-lever double brake.

HUMPHREY JACKMAN.

Further adjourned to Friday, September 29th, at 10.30 a. m.

1694 **Friday**, *Sept.* 29*th*, 1871.

Luke F. Tronson, recalled on the part of the complainant, testifies as follows:

1. Q. In the eleventh question of your previous examination here, I asked you in relation to the general opinion, in respect of the effects of the cross-lever brakes, of the men in charge of the cars, and you answered about the opinion of a particular man—M'r William Pierson—who was foreman of the car shop. Will you now please state, if you know, what was the general opinion in respect of the advantages of the double brake over the single brake of the men, generally, in charge of the cars in the trains? State only what you knew about this matter at or soon after the time when the cross-lever brakes were substituted for the single brakes.

(Question objected to, as the witness has already stated that he had no personal knowledge, but can tell just what others told him about it; that is, as to the comparative merits of the single and double brakes in the matter of sliding wheels.)

A. The general impression among all the men was that the double brake was much the best, as it didn't slide the wheels; we had less trouble with it; the cars didn't have to go into the shop so often for repairs of trucks.

2. Q. What was the general opinion in regard to whether or not the wheels lasted longer with the cross-lever brakes than they did with the single brakes? State only what you knew at the time referred to.

A. The general opinion was that the wheels lasted longer.

1695 Cross-examined by M'r Whipple:

1. Cross-q. Had you conversation with any one but M'r Pierson on this particular subject—of comparison between the single brake and double brake in this matter of sliding wheels?

A. He was the only man I had conversation with that repaired the trucks in the shop.

Redirect:

3. Q. How were the men employed whose general opinion you referred to in your above answers?

A. Outside of M'r Pierson, the men were on the trains that I talked with—brakemen and conductors; he was the only man in the shop.

4. Q. State whether M'r Pierson is living or dead.

A. He is dead.

Recross:

2. Cross-q. Do you wish to be understood that you know nothing of this matter of sliding wheels, whether in the use of the single brake or the double brake, of your own personal knowledge?

A. I know that the wheels slid more with the single brake than with the double brake; I had more wheels to fit up in proportion; I fitted the wheels—it was done under me; I was foreman of the 'hop.

LUKE F. TRONSON.

Adjourned to Thursday morning, Oct. 5th, at 12 m.

Further adjourned to Friday morning, Oct. 6th, at 10 a. m.

1696 U. S. circuit court, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILROAD Company.
In equity.

Testimony upon the accounting in the case, taken at New Haven, Connecticut, this 4th day of October, A. D. 1871.

ALLEN OSTRANDER, being duly sworn, doth depose and say, in answer to interrogatories proposed to him by S. D. Cozzens, esq., as follows, to wit:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Allen Ostrander; 54 years of age; residence, New Haven; and occupation, yard-master on the New York and New Haven Railroad, at New Haven.

Q. 2. How long have you been employed on the New York and New Haven Railroad?

A. Twenty-two years, I believe.

1697 Q. 3. At the time you first went into the employ of the New York and New Haven Railroad Company, what did you do for them?

A. I worked at repairing of cars and examining cars.

Q. 4. What kind of cars, passenger or freight, or both?

A. Both.

Q. 5. About how long a period were you engaged in repairing and examining cars?

A. About eighteen or nineteen years.

Q. 6. At the time you were first employed by the New York and New Haven Railroad Company, what kind of brakes were used on the cars running in their passenger-trains?

A. Single brakes—one on each end of the car.

Q. 7. At any time after you entered their employ was any change made in the brakes used on their cars; and, if so, what change?

A. Yes, sir; there was a change in them from the single to the double brake.

Q. State what kind of a lever or levers the brake to which they so changed had under the centre of the car, if any.

A. It was a single lever under the centre of the car; that was the first change.

Q. State whether or not this lever extended crosswise under the car.

A. It was crosswise under the car.

Q. 10. After this centre-lever double brake was put on to the cars, was there any improvement in the length of time which the car-wheels wore?

A. I do not know how to answer that; we never made a thorough test.

Q. 11. State, from the observation and experience which you had of the matter, whether or not the car-wheels lasted longer after this centre-lever double brake was put on than they did before.

A. Well, they will wear longer.

1698 Q. 12. Stating from your best judgment, about how much longer will the car-wheels wear with such a double brake than with a single brake? Give us your best judgment.

A. Well, I should think they would wear nearly, if not quite, three times as long.

Q. Do you know about how long the wheels under freight-cars which have double-acting brakes upon them wear, as compared with freight-car wheels under the same circumstances, with the single brake? Give us your best judgment.

A. If they are used the same I do not see why there would be any difference between the freight and passenger car wheels.

Q. 14. Do you mean no difference as to the proportional length of wear of the car-wheels between the single-acting brake and the double-acting brake?

A. Using the freight and passenger cars with the same brake, I don't see why they would not last the same on the freight as the passenger car.

Q. What I want to get at is whether you mean that there would be the same proportionate difference in the wear of the wheels between the single and double acting brake on the freight-cars as on the passenger-cars?

A. There would be the same difference under the freight as under the passenger car with the same use, I should think. As I have never tried it, I would not say positive.

Q. 16. While you repaired and examined cars on the New Haven road, did the wheels of the freight-cars, as well as the passenger-cars, come under your observation?

A. They did in repairing, but in examining cars I was more particular on the passenger-cars.

Q. 17. State whether this repairing of the freight-cars gave you an opportunity of observing the effects of the brakes used on those cars, on the wheels, as to the wearing of them.

1699 A. Yes; for I used to take out and put in the wheels, as well as repair the wood-work.

Q. 18. State whether you based your above answers about the wear of the freight-car wheels upon this experience which you say you have had with wheels on the New York & New Haven road?

A. Yes, sir.

Q. 19. What kind of brake, whether double-acting or single-acting, is used at present on the freight-cars of the New York & New Haven Railroad?

A. Double-acting brakes are used. We have no single brakes.

Q. 20. About how many years have they used double-acting brakes on their freight cars on that road?

A. It must be eighteen or nineteen years; I can't say exactly; it may be longer, it may be less.

Q. 21. Do you know about how many freight cars the New York & New Haven Railroad has?

A. I think there are nearly five hundred; between four and five; I can't say exactly how many.

Q. 22. State whether or not on said road they use the double-acting brake on their "flat," or "platform," freight cars, as well as on their "box" freight cars?

A. They use the double-acting brake on all cars. We have no single-acting brakes on the road.

Q. 23. Is the New York & New Haven road what may be termed a first-class railroad?

A. Yes, sir.

Q. 24. Do you know about what is the average life of the car-wheels running on the passenger-trains on the New York and New Haven road, taking one wheel with another?

A. I should say about a year; some wear longer and some not so long.

Q. 25. Do you remember within your experience any cases where wheels under freight cars which appeared to be new had been "flatted"
by the application of single brakes?

1700 A. Yes, sir; I have seen wheels which appeared to be new,
looked as if they had run but a few days, and were "flatted" so
that they were not fit to run, not safe to run.

And in answer to cross-interrogatories proposed to him by S. M. Whipple, esq., he saith:

Cross 26. What brakes are in use on the tenders on the New Haven road, single or double?

A. I don't know; I think they are single. When I answered the other questions I had reference to passenger and freight cars, not to tenders.

Cross 27. Have you had occasion to take out wheels from the tenders of locomotive engines?

A. No, sir; I never had anything to do with the engine department.

Cross 28. Is the centre lever double-acting brake now in use on the passenger and freight cars of the New Haven road?

A. No, sir; I don't know of any on the road.

Cross 29. What double brake is used?

A. The Hodge brake; that has two levers.

Cross 30. What brakes are in use on the freight cars of the New Haven, Hartford and Springfield road, which runs in connection with the New York and New Haven road?

A. I don't know whether they are the Hodge brake or the single brake. As I don't have anything to do with their freight cars, I don't know whether they have the single brake or the Hodge brake, or some other. They may have some other; I don't know.

Cross 31. Why do the wheels wear longer when under the double brake, as you say they do, than when used under the single brake?

A. Because the leverage is put on to eight wheels instead of four.

Cross 32. May not the leverage be so reduced on the single
1701 brake, that is to say, may not the diameter of the windlass wheel
be diminished or the shaft on which the chain winds be so enlarged that the power would be the same on the wheels of one truck, as it is now on the wheels of each truck in the use of the double brake?

A. It could be reduced so as to make it the same, and so that it wouldn't hold at all; it wouldn't hold the cars.

Cross 33. Could it be reduced so that it wouldn't hold at all in the case of the double brake?

A. I suppose it could.

Cross 34. Have you any doubt that it could?

A. You could make the wheel so small that you couldn't turn it hard enough to do any braking; but I do not know what they would do that for.

Cross 35. What applies to the diminution of the size of the windlass to the double brake, does it not equally apply to the single brake?

A. I should hardly think it would in the same proportion.

Cross 36. Why not?

A. Because you have the wheels that you are braking on nearer together; you wouldn't have so long a rod to draw on braking on one truck as you would on two.

Cross 37. Are the wheels any nearer together whether you brake one truck or both trucks?

A. Yes. They are not any nearer together in the truck, but when you are using the double brake the other truck is further away and you have a longer rod to draw on.

Cross 38. Assume that a ten-inch windlass wheel is used to apply the single brake and a thirteeen or fourteen inch wheel to apply a double brake, do you think there would be so great a difference in the wear of wheels as you have stated in your direct examination ?

A. They can reduce the leverage of the single brake so that it wont hold any harder nor so hard as the double brake if they want to.

1702 Cross 39. In case of such reduction, do you think the difference in wear between the two brakes would be so great as you have stated ?

A. No, if they did it; but they don't. I never saw them reduced so much as that. Here, we used the same windlass wheel when we put on the double brake as we did when we used the single brake.

Cross 40. Did you ever keep an account of the time that wheels run under the single brake, and also the time which they run under the double brake, so as to enable you to institute a comparison between the two brakes in the matter of wearing wheels ?

A. I never kept a regular account. I never made a regular test of it, as I have heard they have done on other roads, but I have noticed that wheels had not been slid as much to flatten since we have used the double-brake as they did before.

Cross 41. What have you heard of being done on other roads in the way of keeping an account, and from whom have you heard it ?

A. I heard that they kept a regular account at one time on the Hudson River road. That was M'r Sayles told me that. I don't know what his first name is.

Cross 42. Was it the man who first saw you in reference to taking your testimony in this case ?

A. Yes, sir.

Cross 43. What did he state to you as the result of this account kept on the Hudson River road ?

A. That the wheels under the double-acting brake would last four times as long as the wheels under the single-acting brake. I think he said that, but I wouldn't be sure whether it was three or four times.

Cross 44. Did M'r Sayles state to you what other witnesses had testified to on this point of the comparative wear of wheels under the single and double brake ?

A. No; I believe not.

1703 Cross 45. Assume that the New Haven, Hartford and Springfield road are using single brakes on their freight cars, is it your opinion that that company is destroying three sets of wheels by the use of the single brake as against one set used under the double brake by the New York & New Haven road which runs in connection with the aforesaid road ?

A. Well, I think if they used the single brake where we do the double brake on the New York and New Haven road, they would wear out more wheels.

Cross 46. Do you think that they would wear out three sets of wheels by the use of the single brake as against one set on the New York road ?

A. Well, I don't know as they would on their road, for their road is shorter, and there are fewer stations on it, and there would consequently be less braking.

Cross 47. Suppose the roads were of the same length, and had the same number of stations, do you think the Hartford and Springfield road would wear out three sets of wheels as against one set by the New Haven road?

A. Well, as I said before, not having tested it, I think they would wear out three sets to one on the New York road; but not having tested it, I would not swear to it, but I should think they would wear out three to one.

Cross 48. Will you swear to the same—in reference to the same—with reference to the passenger and freight cars on the New Haven road, or did you merely state it as your opinion?

A. I state it as my opinion.

Redirect:

Q. 49. Suppose the leverage of the single brake was reduced, as inquired about on the cross-examination, do you think that the brake would do efficient braking under the circumstances which occur practically on railroads?

1704 A. Well, if you should reduce the leverage on a single brake so that it is less than it is on the double brake when the double brake's leverage is just right, the single brake's leverage would be too small to do service.

Q. 50. Do you think that when the leverage on the single brake is reduced, as suggested in the cross-examination, it would be too small to do service?

A. I think it would have hardly power enough to do service, but I wouldn't swear. I never saw the attempt made. I think I never saw so small a wheel used on the windlass.

Q. 51. Have you based your answers in this deposition upon your own observation with respect to car-wheels, or upon what M'r Sayles may have told you?

A. I have spoken principally from what I have seen with respect to wear of wheels.

Recross:

Cross 52. To produce efficient braking of a car, is it necessary to slide the wheels?

A. No, sir; it doesn't hold so well when the wheels are sliding as it does when the wheels are just rolling a little.

Cross 53. May not the leverage of a single brake be so graduated as to do efficient braking, and not slide the wheels?

A. I think it may.

ALLEN OSTRANDER.

1705 Hebron T. Douglass, being duly sworn, doth depose and say, in answer to interrogatories proposed to him by S. D. Cozzens, esq., as follows, to wit:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Hebron T. Douglass; age, fifty-three years; residence, New Haven. Am not engaged in any business at present; have been car-master on the New York and New Haven Railroad.

Q. 2. About how long were you in the employment of the New York & New Haven Railroad Company?

A. A little over seventeen years as car-master, and between two and three years previous to that as a journeyman.

Q. 3. While you were car-master on the New York & New Haven road, what were your duties?

A. My duties were to build, repair, and the general oversight of the cars; had charge of the shop; was superintendent of the car department.

Q. 4. State whether taking out old wheels from the cars and putting in new ones came within your department.

A. It did.

Q. 5. How long since you left the employ of the New York & New Haven road?

A. Something over two years.

Q. 6. When you first went into the employ of said railroad, were there any brakes in use on their cars of the kind known as single-acting brakes?

A. There were some, to the best of my recollection.

Q. 7. Were those single brakes taken off at any time while you remained in their employ; and, if so, what was substituted for them?

A. All that were on while I was in their employ were taken off, and the double-acting brake put on.

Q. 8. Do you know what name these double-acting brakes which were put on went by?

1706 A. There were, I think, three kinds of double-acting brakes tried at different times—Tanner, Hodge, and Stevens.

Q. 9. Which one of these double-acting brakes was first used on the New York & New Haven road?

A. The single lever in the centre of the car—I think the Tanner.

Q. 10. While you were car-master on said road did you see the cars of other railroads, with single brakes upon them, come over the New York & New Haven road?

A. Yes, I did.

Q. 11. While you were so car-master did it come within your duties to notice the wear produced on the wheels by the use of single-acting brakes, and also by the use of double-acting brakes?

A. Yes; it did.

Q. 12. Will you state whether, in your judgment as a railroad man and a car-master, the car-wheels, under given circumstances, will wear any longer when such a double brake as the Tanner brake is used than they will when the single brake is used?

A. I do think they wear longer.

Q. 13. In your judgment, about how many sets of wheels would be required—in say a year—for a passenger car using the Tanner double-acting brake, and how many for the same car, in the same time, if the single brake be used?

A. It would take, with the Tanner brake as we used to use them on that road, a little over one set of wheels a year. I presume it would take three sets using the single brake.

Q. 14. You say "presume." What is your judgment?

A. That is my judgment.

Q. 15. Do you think, taking the weight of cars and speed of trains as they are at the present day, that the single-acting brake could be used with safety on passenger-trains, as a general thing?

A. I do not.

1707 Q. 16. Will you please state, if it is within your knowledge, what kind of brakes are used on both the "flat" and "box" freight cars of the New Haven and Northampton Co., commonly called the Canal Railroad?

A. It is the Hodge brake, double acting.

Q. 17. Will you also please state, if you know, what kind of brakes are used on the freight cars of the Housatonic Railroad, Nagatuck Railroad, Danbury & Norwalk Railroad, and Shore Line Railway?

A. I think they all use the Hodge brake, double acting.

Q. 18. How many of the railroads named in the last two questions are what may be called first-class railroads?

A. They are all good roads.

And in answer to cross-interrogatories proposed to him by S. M. Whipple, esq., he saith:

Cross 19. What kind of brakes are used on the freight equiyment of the New Haven, Hartford and Springfield road?

A. I think they use mostly, if not altogther, the single brake on that road.

Cross 20. What other roads in the United States are using the single brake on their freight equipment?

A. The Boston & Albany use, I think, the single brake, and I think the Rutland & Burlington. Quite a number of those Northern and Eastern roads use them, but I am not acquainted with them all.

Cross 21. So far as your knowledge extends, is not the single brake used on freight cars with the exception of those named in your direct examination?

A. No. I know of other roads that use the double brake on their freight cars.

Cross 22. What other roads?

1708 A. The New York & Harlem. I think the New York Central use the single brake on their freight cars.

Cross 23. Is it your judgment, as a railroad man, that railroad companies, by using the single brake instead of the double brake on their freight cars, are destroying three sets of wheels per year by so doing, as against one set, or thereabouts, if the double brake were used?

A. That would be my judgment.

Cross 24. Upon what do you base such judgment?

A. From observation.

Cross 25. What has been your observation with reference to the matter inquired of?

A. My observation perhaps has been as much of cars of other companies that came into the yard here with the single brake on. I have noticed car wheels come into the yard here—you can't tell by the looks of wheels just how far they have run—but apparently new wheels—that had been slid or worn flat with the single brake till they were not safe or fit to run at quick speed.

Cross 26. Have you not observed the same in cars when the double brake was used?

A. Not to the same extent; I have to some extent, a little flat spot.

Cross 27. Have you ever kept any record of the wear of wheels when used under the single brake, and also under the double brake, and compared the result one with the other?

A. I have not.

Cross 28. Is there any way known to you whereby you can so modify the leverage, whether as applied to the single brake or to the double brake, so as to, in a great measure, prevent the sliding of the wheels?

A. Oh, you can prevent the sliding of the wheels. You can reduce your leverage so as not to slide your wheel.

1709 Cross 29. Can this be done practically in either case—that is, with the single or double brake?

A. It could with the double brake, and so it could with the single, but not so as to make it (the single brake) a very efficient brake.

Cross 30. Please explain why your answer applies to the double brake and not to the single brake?

A. To begin with, I don't think the single brake a very efficient brake any way.

Cross 31. Is any brake, in your judgment, an efficient brake, whether single or double, that has not sufficient leverage to enable the brakeman to slide the wheels?

A. Yes.

Cross 32. Do you know of any double brake the leverage of which is so arranged that the wheels are not slid more or less?

A. No; I do not know that I do.

Cross 33. Then is it not necessary that any brake should have the resident force in it to slide the wheels in order to be efficient?

A. No, I don't think it necessary to slide the wheels in order to make an efficient brake. I will add that under some circumstances, viz, when the track is wet, a brake will cause a wheel to slide much easier than when the track is dry.

Cross 34. Do you think wheels are slid as readily, whether the single brake or the double brake is used, since the adoption of iron for brake shoes?

A. No, I don't think they are slid as readily.

Cross 35. Would not this fact somewhat modify your judgment as to the margin between wheels worn out under the single brake, compared with the double brake?

A. No, I don't think it would, as I notice that on a number of the roads where they use the wood shoes yet.

1710 Cross 36. On what roads?

A. I think they do on the Boston and Albany; I would not swear to that, for I haven't noticed very much about their cars within the last two years.

Redirect:

Q. 37. About how long ago was iron adopted on the cars of the New York and New Haven Railroad for the shoeing of the brakeheads?

A. Well, I should say fifteen or eighteen years ago.

Q. 38. About how long ago was iron adopted for this purpose on the cars of some or all of the roads connecting with the New York and New Haven road and the cars of which you used to see come over the latter road?

A. When I left the New York and New Haven road iron was not used on all the cars of other roads which ran over that road; it was adopted on some of them ten or twelve years ago.

Q. 39. State whether you ever saw any reason to change your opinion as to the relative wear of the car-wheels as between the single brake and the double brake after such adoption of iron for the brake shoes?

A. I do not know as I have.

Q. 40. You were asked, on cross-examination, whether you ever kept an account of the wear of the wheels with the single brake. Will you state whether you consider it necessary to have kept such account to enable you to form the judgment you have given in this testimony?

A. No, I don't think it is necessary.

Q. 41. You stated that you had noticed some little flat spotting of wheels in cars which had the double brake. Please state what form of double brake the cars you referred to had—the Tanner, Hodge or Stevens?

A. The Hodge—perhaps more from the fact that I had more to do with them.

1711 Q. 42. Assume that a car with a single brake had its leverage reduced as inquired about on the cross-examination, so that the brake could not under any circumstances slide the wheels, would or not a brake having no more power at any time than that be, in your judgment, an efficient brake for practical use?

A. I should not think it would, in my judgment.

Q. 43. Suppose a single brake is so adjusted that the power which it exerts upon its truck is no greater at any time than the power exerted by a double brake upon each one of the trucks, would or not, in your judgment, the greater number of points of simultaneous fractional contact in the case of the double brake affect materially the question of the efficiency of such double brake as compared with such a single brake?

A. Well, of course, as I understand it, it would be two to one.

Q. 44. Please state whether or not this fact constitutes an important reason why the double brake can do its work without requiring power enough to be applied to slide the wheels, and thereby "flat" them and spoil them, even though it has such reserve power in it, when, as ordinarily used, the single brake cannot?

A. It is.

Re-cross:

Cross 45. Assume that a car with a double brake has its leverage reduced so that the brake could not under any circumstances slide the wheels, would or not a double brake, having no more power at any time than that, be in your judgment an efficient brake for practical use?

A. No, I do not think it would.

Redirect:

1712 Q. 46. Would or not such a double brake as just inquired about be more efficient than a single brake, which could not under any circumstances slide the wheels?

A. It would, I think, in proportion two to one.

H. T. DOUGLASS.

UNITED STATES OF AMERICA,
District of Connecticut, ss:

I, Jonathan Ingersoll, a commissioner duly appointed by the circuit court of the United States for the district of Connecticut, under and by virtue of the act of Congress "for the more convenient taking of affidavits and bail in civil causes depending in the courts of the United States," passed Feb. 20th, 1812, do hereby certify that the reason for taking the foregoing depositions is, and the fact is, that the testimony of the witnesses aforesaid is necessary in the cause in the caption of the said depositions named.

And I further certify that on the 4th day of October, in the year of our Lord one thousand eight hundred and seventy-one, I was attended by S. D. Cozzens, esq., counsel for complainant, and by S. M. Whipple, esq., counsel for respondents, and by the said witnesses; and each of the said witnesses was by me first carefully examined and cautioned and sworn to testify the whole truth, and the testimony by them given was by me reduced to writing, and thereafter subscribed by the said witnesses in my presence.

And I further certify that I am not of counsel or attorney to 1713 either of the parties, nor in any way interested in the event of the cause named in the caption.

In testimony whereof I have hereunto set my hand and seal this 4th day of October, in the year of our Lord one thousand eight hundred and seventy-one, and of the Independence of the United States the ninety-sixth.

JONATHAN INGERSOLL,
United States Commissioner for the District of Connecticut.

FRIDAY, *Oct. 6th*, 1871.

FREDERICK NEVIUS, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Frederick Nevius; age, thirty-three; residence, Jersey City Heights; occupation, car-inspector.

2. Q. Are you in the employ of any railroad company; and, if so, of what company?

A. I am. The New Jersey Railroad Company.

3. Q. How long have you been in the employ of that company?

A. Four years next June.

4. Q. In inspecting cars for that company, do you have charge of any particular trains; if so, what trains?

A. I do; of the New York and Washington through line.

5. Q. Have you had charge of the cars in this through line during the whole of the time you have been in the employ of said company?

A. I have not.

6. Q. For about how long have you had charge of said through-line cars?

A. I think it is nearly three years.

7. Q. In inspecting the cars of said line, what kind of duties do you have to perform?

A. I have to examine the wheels; examine every bolt and nut on the cars to see that they are properly screwed up, and repairing to be done on them; I have to see that it is done. If I can do it myself, I have got to do it. I have to keep the cars in running order.

8. Q. State whether or not these duties of yours, with regard to these cars, require you also to examine and keep in repair the brakes on these cars?

A. They do.

1715 9. Q. What kind of brake is used upon the cars in said through line furnished by the Camden & Amboy and New Jersey Railroad Companies?

A. The centre-lever brake.

10. Q. What kind of brake is used on the cars in said line furnished by the Philadelphia, Wilmington & Baltimore Railroad Company?

A. A long rod brake; the Stevens patent.

11. Q. Do the above duties which you have spoken of as performed by you about the cars of this through line, enable you to know when the wheels of the cars are too much worn to run properly?

A. They do.

12. Q. State whether you find any difference in the wearing of the car wheels in this through line between the said cars having the Stevens brake and the cars having the centre lever brake.

A. I have been thinking of that since I was asked the question awhile ago, and I think the wheels with the center-lever brake wear out the fastest. I have nothing to go by only my memory.

13. Q. About how long, according to your observation, do the wheels of the cars in said line with the center-lever brake wear on the average?

A. From ten months to a year.

Cross-examined by M'r Whipple:

1. Cross q. How long do they last on cars that have the Stevens brake on?

A. A year and a half.

FREDERICK NEVIUS.

1716 FREDERICK NEVIUS, recalled on behalf of the complainant:

1. Q. In speaking above of wheels which lasted a year and a half with the Stevens brake, what kind of wheels did you refer to?

(Objected to, as the witness has been taken from the stand and conferred with and recalled.)

A. I referred to steel wheels.

2. Q. Referring now to the regular cast-iron wheels of the cars in said through line which have the Stevens brake, and the regular cast-iron wheels of the cars of the New Jersey road in said line having the center-lever brake, please state which wear the longest, or whether you find any difference in the wear of them.

A. I can't say that I see any difference.

Cross:

1. Cross-q. Which brake distributes the power exerted by the brakeman on the wheel more equally, the Stevens brake or the center-lever brake?

A. That is pretty hard for me to answer, as I am not a brakeman. My impression is that the center-lever brake does.

2. Cross-q. Do you have the taking out and the putting in wheels at Jersey City of the cars of the Philadelphia, Wilmington & Baltimore road, which have the Stevens brake?

A. I do of the cars belonging to the Washington line; that is, I help to.

3. Cross q. Do you take them out from cars belonging to that company to the same extent that you do from the cars of the New Jersey and Camden and Amboy Companies in that line?

1717 A. It is only incidentally—as I have occasion.

4. Cross-q. When the cars need renewal of wheels, are they as a general rule sent to the shops of the company at Wilmington for this purpose?

A. Just as it happens about that; if they want a whole set they do. It is just as it happens; we have put in whole sets here.

5. Cross-q. Where are the wheels of this company more generally put in—at Wilmington or at Jersey City?

A. Just as it happens. If they want them at Jersey City, and there are no other repairs, they put them in. If there are other repairs besides wheels, they send them to Wilmington.

If they have got the wheels they put them in at Jersey City; if they haven't got the wheels, they send them to Wilmington.

FREDERICK NEVIUS.

PATRICK S. DEVLAN, recalled on behalf of the complainant:

1. Q. For about how many years of the time you were practically employed upon railroads, as you stated here the other day, were you engaged as locomotive engineer?

A. About fifteen years.

2. Q. During about how many years of this fifteen were you engineer of passenger trains the cars of which had single brakes on them?

A. The greater part of the time; I can't state exactly.

3. Q. State how the fact was as to whether the reversing of 1718 the locomotive, under steam, was generally relied upon to aid in stopping trains in the days when single-acting brakes were used on the passenger-cars.

A. It was.

4. Q. State whether such reversing of the engine under steam is, or not, dispensed with since the double-acting brake—whether the centre-lever brake or any other kind of double-acting brake—has been introduced upon railroads.

A. It is dispensed with.

5. Q. Please state what is the effect upon a locomotive of reversing it under steam.

A. It would be under a full head of steam or under general headway, a racking of the engine.

Cross-examined by M'r Whipple:

1. Cross-q. In what year did this fifteen years of your service as engineer commence, and on what road?

A. In 1835; on the Tamaqua road.

2. Cross-q. Was it on this road that you were in the habit, as an engineer, of reversing the engine to stop the trains, or on some other road or roads?

A. On that road and others both. On the Harrisburgh & Lancaster, also what was called at that time the Columbia road, Lebanon Valley, and the Philadelphia & Reading road.

3. Cross-q. Was this reversing of the engine to stop the train done in any other cases than those of emergency?

A. It is a hard question to answer. I have reversed an engine and slid all the wheels in a train for thirty or forty yards; that was a very frequent thing. It was not as a general rule.

1719 Redirect:

4. Q. You have said above that when the single brake was used on passenger-trains, the reversing of the engine was generally relied upon to aid in stopping the trains. I now understand you to say that this reversing was not done except in cases of emergency. Will you please explain what you mean?

A. It was always relied upon, the reversing of the engine to stop the trains, with the single brake. I did not understand the third cross-question. It was a general rule always to reverse the engine.

Recross:

4. Cross-q. You say you have reversed an engine and slid all the wheels on a train for thirty or forty yards; does reversing the engine slide the wheels of the cars in a train?

A. No. I meant the wheels of the tender, and the driving-wheels of the engine revolving the contrary way.

5. Cross-q. Does the reversing of the engine have anything to do with sliding the wheels of the tender?

A. No, sir. The brakeman, or the fireman I should say, always applied the brakes to the tender the instant the engineer reversed.

6. Cross-q. Did you reverse the engine at all stopping-places or stations as a general rule?

A. Yes; always.

7. Cross-q. What effect did this reversing have on your engine?

A. If it was so severe that the wheels revolved the other way, it wore the tire very much. We generally gave it steam when we reversed, and it strained the other parts of the machinery.

1720 8. Cross-q. How long would an engine run with this constant reversing and straining of machinery before it would have to go into the shop for repairs?

A. As a general rule, that I can't answer. Some would be out a week, some three months; that would depend upon circumstances.

9. Cross q. Were the cars used single-truck cars in trains run by you in the early time of your railroading?

A. Yes; first part single and latterly double.

10. Cross-q. Do you allude to single-truck cars when you speak of reversing the engine to stop the train?

A. I allude to the four-wheel cars. There were no trucks, nothing like a truck, when I commenced. I allude to both four-wheeled and eight-wheeled cars. When I commenced they had nothing but four-wheeled cars. They afterwards got the trucks.

11. Cross-q. After the application of the double brakes to cars, did you reverse the engine to stop the train in cases of emergency?

A. In cases of extreme emergency we did—in danger of collision or anything of that kind; running over anything—but not as a general rule.

P. S. DEVLAN.

CYRUS W. BURTON, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Cyrus W. Burton; age, fifty one; reside in Bridgeport, Conn.; occupation, locomotive-engineer.

2. Q. Are you at the present time employed on any railroad; if so, what railroad?

A. I am; on the Morris and Essex Railroad.

1721 3. Q. Have you been employed on any other railroads than that as locomotive engineer; if so, what roads?

A. I have; on the New York and New Haven Railroad, and the Pennsylvania Central.

4. Q. About what year, as near as you can recollect, did you commence running as locomotive engineer on the New York and New Haven road?

A. About 1849.

5. Q. For about how many years did you continue to run on said road as locomotive engineer?

A. Seventeen.

6. Q. At about the time, and for a while after you commenced to run on the New Haven Road, what kind of brakes, whether single-acting or double-acting, did they use on the cars running in their passenger-trains?

A. What is termed the single brake; that is, attached to one truck.

7. Q. In those days, when they used the single-acting brake on their passenger-trains, did the engineer do anything to aid in stopping the trains at stations; if so, what did he do?

A. If the brakes did not hold, the engineer reversed the engine to stop the train at the point he wished to stop at the station.

8. Q. Taking one day with another, about how much of the time did the

engineer have to reverse his engine to aid in stopping the train when the single brakes were used on the cars?

A. About half the time.

9. Q. While you continued to run upon the New Haven road as locomotive engineer, was there any change made in the brakes used on their cars; if so, what was the change?

A. Yes, sir; the change was from what we termed the single brake to the double brake; that is, a brake attached to both trucks, the forward and rear trucks of the car.

1722 10. Q. After these double brakes were introduced on said road, what kind of trains did you run on as engineer?

A. Passenger, both "way" and express. "Way" trains stop at all the stations; express, at a portion of them.

11. Q. About how many cars were there in those express-trains?

A. The average express-train would be about ten or twelve cars.

12. Q. Were there any of those express-trains at any time which had more cars?

A. Yes, sir.

13. Q. How many more?

A. Well, it depended on the travel. The average was, as I have stated, ten or twelve cars. Sometimes, for a quarter of the time, they would run up to sixteen or eighteen.

14. Q. With these heavy trains of more than ten or twelve cars, did you have to reverse your engine in stopping at stations; and, if so, about how often, say in a month, after they used the double brake on the cars?

A. No, sir; it hardly ever occurred that we had to reverse the engine at the stations; not once in six months.

15. Q. What is the effect on the engine of reversing it while under headway?

A. Well, the effect is injurious to the engine in reversing it.

When you reverse your engine with steam on it, you have the whole power of the engine going one way, and then when you put on the steam the other way, it throws the steam back into the boiler, and the effect on the engine is to rack every bolt and nut in it, as if you struck it with a sledge-hammer.

16. Q. How much longer do you think an engine can run without having to go into the shop for repairs, when it doesn't have to be reversed under steam any oftener than you have stated it does
1723 when the double brake is used, than it could if it had to be reversed as often as when the single brake was used? State to the best of your opinion.

A. My opinion is that it would run one-third longer without reversing than when it was; one-third longer when it did not have to be reversed than when it did.

17. Q. Please state how the fact is as to the small repairs, such as would be done in the round-house without sending the engine into the shop, when the engine is not reversed any oftener than is required with the double brake as compared with what it would be with the single brake.

A. It should run twelve months without reversing, except the round-house repairs. As to round-house repairs, it would make very little difference as to that, as there would be only what one man could do in the round-house. With the reversing, it would have to go into the shop in about eight months; without reversing, in about twelve months, making about one-third difference, as I stated.

Cross-examined by M'r Whipple:

1. Cross-q. How many brakemen were employed on the passenger-trains on the New Haven road run by you, as a general rule, when single brakes were used?

A. As a general rule one to three cars.

2. Cross-q. What number, as a general rule, were employed when they used the double brake?

A. The same number.

3. Cross-q. Had there been placed a brakeman at each car in the train or between every two cars do you think there would have been any necessity of reversing the engine to aid in stopping the train when single brakes were used?

1724 A. The cars we were running at that time had the single brake on only one end, and if you wanted to get to the brake of the next car you had to pass through the car. This was sometimes the case when the ends of the cars having the brakes on didn't come together.

4. Cross-q. Assume that the single brake is applied to each truck of the car or cars of the train, would a brakeman between every two cars in a train so control the train as to render the reversing of the engine unnecessary?

A. It is my opinion he would not.

5. Cross-q. At what time did the New Haven road run on an average ten or twelve cars in its passenger-trains?

A. I don't mean to say that every passenger-train had that, but many of them since in 1850.

6. Cross-q. What, in your judgment, would be the average, taking all passenger-trains through the year, both local and express?

A. It would be impossible for a man who hadn't a report of the trains—the number of cars in the trains—to say.

7. Cross-q. Is it equally as impossible for you to state that an engine would run twelve months drawing trains in which the double brake is used before it would have to go into the shop for repairs, compared with an engine drawing trains upon which the single brake is used having to go into the shop for repairs in eight months on account of reversing the engine?

A. No, sir. In my experience an engine will run twelve months before going into the shop without reversing, as it would go into the shop with reversing in eight months. That is what I mean, that an engine will run better twelve months without reversing than it will eight months with reversing.

8. Cross-q. Every time you reversed your engine did you throw it completely over and reverse the driving-wheels or slide them upon the rail?

1725 A. When we reversed an engine we threw it clear over, but owing to the difference of the rail being wet or dry—on the dry rail the wheels do not always slip or slide—the damage was greater to the engine for not slipping than if they did. I mean by that that they do not always turn backwards.

9. Cross-q. Do you wish to have it understood that you reversed your engine at every other station that you had to stop at on an average; if not, what do you wish to be understood?

A. I mean to say that we reversed the engine at half the stations in going over the road.

10. Cross-q. Was not this reversing of the engine in a great measure owing to the fact you have already stated, that the cars had brakes only on one truck of a car, and not on two trucks, as is usually the case?

A. That is what we were obliged to do, with the brakes on only one end, to stop the train; if they had brakes on each end of the car, and all the brakes been applied, there would have been no necessity of reversing the engine to stop the train, that is, if they were applied at the proper time.

11. Cross-q. Were you running a passenger-train at the present time equipped with double brakes, and you were likely to run by a station, would you reverse your engine to prevent your so doing, or would you wait till the train stopped and then reverse and back up?

A. I should reverse my engine and stop, if my brakes failed.

12. Cross-q. Do you now reverse your engine at stations if you see that you are likely to run by the place where you want to stop?

A. I think I said in answer to the other question that if it occurred I did.

13. Cross-q. Does it occur on the road you are now running on?

A. It has once in three months.

1726 14. Cross-q. Do you say that you have run a passenger-train three months, and only run by a station once in that time?

A. I say that I have reversed my engine but once at a station in three months, for receiving and discharging passengers.

15. Cross-q. Do you mean by that that you have not run by a station for receiving and discharging passengers but once in three months?

A. I do, so as to be obliged to back up.

16. Cross-q. How many cars in such trains, and how many brakemen in the three months spoken of?

A. Six or seven cars, and two brakemen.

17. Cross-q. Would not, in your judgment, the result been the same if you had had the single brake on the same cars and four brakemen working and operating the brakes simultaneously?

(Objected to as it might be impossible for four brakemen to apply all the brakes with the single brake simultaneously.)

A. Well, my judgment is, if you guarantee the four men to work simultaneously, I've no objection, but should prefer the two; it might make little difference how the power is applied if it is applied simultaneously, the four men or the two.

18. Cross-q. When the single brake was used were the conductor and baggage-man in the habit of braking, in connection with the brakemen?

A. Not on the trains I was running.

19. Cross-q. On the trains which you were running on the New Haven road you have said that one brakeman was employed to three cars on an average, and that brakes were applied to but one truck of a car. How many brakes in that case would, as a general thing, be available on a train of six or seven cars toward stopping the train with the single brake?

A. There would be from three to four trucks available; if the 1727 ends of the cars having brakes on came together there would be four; but if not, only two.

20. Cross-q. At what speed, on an average, were trains run on the New Haven road at the time single brakes were used?

A. Way trains, twenty-three miles an hour; express trains, thirty-one and a half.

Redirect:

18. Q. How many brakemen would it require to apply the brakes to all the wheels of a train of six eight-wheeled cars with the single brake?

A. Seven.

19. Q. How many with the double acting brake?

A. Three.

20. Q. What effect does the single brake have upon the wheels of a car?

A. If well applied, it has a tendency to slip the wheels.

21. Q. What effect does this slipping have?

A. It makes flat places on the tread of the wheels.

22. Q. Will the brakes stop the trains as readily when the wheels slip on the track as when they do not?

A. They will not.

23. Q. Are the double brakes, or are they not, as liable to slide the wheels as the single brakes?

A. They are not.

24. Q. Then, if the single brakes are more liable to slide the wheels than the double brakes, is it your opinion that four men with the single brake would stop the train as regularly at the stations as two men would with the double brake?

A. I should prefer the two men with the double brake. There would be little difference, in my opinion, with regard to stopping the train. If I were master mechanic, and had regard to the wear of the wheels and machinery, I would prefer the two men to the four.

1728 25. Q. What, in your opinion, would be the damage to an engine in consequence of reversing with the single brake, as you have stated, in one year, or running the same time with the double brake?

(Objected to.)

A. It is difficult to get at the exact sum. One thousand dollars difference.

Recross:

21. Cross-q. In what way do you come to this conclusion that an engine is damaged a thousand dollars by reversing consequent upon the use of the single brake instead of the double brake?

A. It has the effect of loosening the bolts, of sucking ashes and cinders from the smoke arch—cutting your cylinders and valves, and causing your flues and furnace to leak.

22. Cross-q. Was the master mechanic of the New Haven road aware of this damage to engines, and yet continued running trains the cars of which had a brake on only one truck of a car?

A. I couldn't answer that question, for I know nothing about his business; but he must have been.

23. Cross-q. Would, in your judgment, there have been a remedy for this reversing the engines to stop at stations had the company applied the single brake to each truck of a car, and increased the number of brakemen to say two to three cars instead of one?

A. That probably would have remedied it to some extent.

24. Cross-q. Would it not almost, if not entirely, have obviated the necessity of reversing, providing each man did his duty as he now does with the double brake?

A. Well, it might to some extent—how much I don't know.

CYRUS W. BURTON.

1729 JAMES E. HUTTON, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. James E. Hutton; fifty years of age; residence, Jersey City; occupation, locomotive engineer.

2. Q. About how many years have you been running as locomotive engineer?

A. Well, about thirty years.

3. Q. Upon what railroads?

A. The New Jersey Railroad, the Erie Railroad, the Staten Island, the Harlem, the Charleston & Northeastern, the Charlotte & South Carolina, and the Texas & New Orleans.

4. Q. Are you at the present time employed upon any road as locomotive engineer; if so, what road?

A. Yes, sir; the New Jersey Railroad.

5. Q. About how long have you been locomotive engineer on that road altogether?

A. I have been there five different times—sixteen or eighteen years altogether. I have been there eight years this last time.

6. Q. At any time while you have been engaged as locomotive engineer, were single-acting brakes used on the cars in the trains which you run?

A. Yes, sir.

7. Q. What kind of trains were these?

A. Passenger trains and freight trains—both kinds.

8. Q. With these passenger trains using the single brake, did you as engineer have to do anything to aid in stopping the trains at stations; if so, what did you have to do?

A. I had to reverse my engine to stop them sometimes; sometimes I didn't.

9. Q. About how much of the time did you as engineer have to reverse you' engine to aid in stopping the trains with the single brake?

A. Full half the time.

1730 10. Q. At any time while you have run as engineer has there been any other kind of brake than the single brake used on the cars in your trains; if so, what kind of brake?

A. There has—the double brake.

11. Q. What kind of brake is used on the cars run by you in the trains on the New Jersey road at the present time?

A. The double brake.

12. Q. What kind of double brake?

A. A double lever brake—I believe the name is the Tanner.

13. Q. In stopping trains with the Tanner brake, do you have to reverse your engine; if so, about how much of the time?

A. Well, it is very seldom we do it now, very seldom we have to reverse the engine.

14 Q. What is the effect upon the engine of reversing it under headway?

A. It strains the engine, and affects it in a number of different ways.

15. Q. State whether or not an engine would run any longer without requiring to be sent into the shop for repairs when the Tanner double brake is used on the trains, than when the single brake is used; if so, how much longer, to the best of your opinion?

A. It would go to the shop quicker on the single brake—when we reversed; I think the engine would run as long again—double the length of time—when run as it is now with the double brake as compared with the way it was when the single brake was used.

16. Q. When the single brake was used on the trains you run, did you notice the effect of the brake on the car wheels?

A. I noticed them having flat places in them very often.

17. Q. Was there any improvement in this respect after the Tanner brake was introduced; if so, what was the improvement?

1731 A. I think there was. There were not so many flat wheels—very seldom I ever heard of one.

18. Q. How much, if any, longer do the car-wheels last with the Tanner double brake than they used to last, according to your observation, with the single brake?

A. I think they last as long again.

Cross-examined by M'r Whipple:

1. Cross-q. How many brakemen were employed on the trains run by you when the single brake was used?

A. Sometimes one, sometimes two—according to the number of cars we had.

2. Cross-q. How many brakemen on an average?

A. I never knew more than two on one train when we run with the single brake.

3. Cross-q. How many on an average were employed when the double brake was adopted?

A. They have about two to a train; sometimes they have more.

4. Cross-q. Could you not have avoided reversing the engine—stopping at stations—when you used the single brake by shutting off steam further from the station than is customary when you have the double brake?

A. Yes. I suppose you might have shut off steam so far off as to let the train run in without any brakes at all. But if you want to make any kind of time you have got to take all the chances to make the time.

5. Cross-q. If you were obliged to reverse the engine half of the time why not all the time?

A. Sometimes they hold better than they do at others—the brakes.

6. Cross-q. On the same grade and the same condition of track, would not the brakes hold, as a general rule, as well at one time and place as another?

1732 A. If they were in proper condition and applied in the same way, I suppose they would.

7. Cross-q. Were you to disconnect the brakes that are now used, running them as single brakes, would you have to reverse the engine in order to enable you to stop at stations, if the brakes were well kept up?

A. I think you would.

8. Cross-q. Is there any rule on the New Jersey road against the reversing of the engine?

A. Not that I know of.

9. Cross-q. Is there any rule forbidding brakemen to slide the wheels?

A. I don't know that there is; I don't know what orders the brakemen have.

Redirect:

19. Q. About how many cars, on the average, did there use to be on the trains on the roads where you ran in the days when the single brake was used?

A. I never ran on any road where the single brake was used except the New Jersey road and the Harlem road. On the Harlem road they used to run one to two cars in a train, and they had one brakeman. On the New Jersey road they used to have about one brakeman to three cars; the Newark train had about three cars and had one brakeman; the Philadelphia train had about five or six cars and two brakemen.

20. Q. How many cars do the passenger trains of the New Jersey Railroad average at the present time?

A. The principal trains run through; they have from eight to twelve cars; I had twelve cars in my train coming in this morning.

21. Q. Which were the heaviest—the cars in the days when they used the single brake, or the cars at the present day?

A. Oh! the cars at the present time.

22. Q. How much heavier are they at the present time, to the best of your opinion?

1733 A. Well, I should judge they are double the weight, if not more.

23. Q. With those trains, in the days when they used single brakes, did one brakeman apply more than one brake? If so, please tell how he did it.

A. One brake was about all they applied—when they had only one brakeman to a train.

24. Q. With cars of the weight which you say they have at the present time, would two brakemen to a train averaging five or six cars be sufficient to stop the train if the single brake was used?

A. Not at the speed we run now.

25. Q. Would it, in your judgment, be safe to run railroad trains, at the present day, if the double brakes were disconnected, and used only as single brakes?

A. I think not.

JAMES E. HUTTON.

1734 United States circuit court, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO & NORTHWESTERN RAILROAD Company. } In chancery.

Testimony taken on final accounting in the case before H. W. Bishop, esq., master in chancery, at Philadelphia, this seventh day of October, 1871.

JOHN P. RAY, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. John P. Ray; age, thirty-six; residence, Philadelphia; occupation, car-builder.

2. Q. By what railroad company are you at present employed, and how long have you been employed by it?

A. The Philadelphia & Westchester Railroad Company; I have been employed by that company two years.

3. Q. Did you have anything to do with any railroad before you

1735 were employed by that company; if so, what railroad, and in what capacity were you connected with it?

A. Yes, sir; the Camden and Atlantic, the Raritan and Delaware Bay, the North Pennsylvania, and the Philadelphia, Germantown & Norristown. I was foreman of the repair-shop of the Camden & Atlantic. I was on that road about three years. I was master of car-repairs on the Raritan & Delaware Bay for about two years. I was journeyman in the repair-shop of the North Pennsylvania for about six months. I was journeyman in the repair-shop of the Philadelphia, Germantown & Norristown for about eighteen months.

4. Q. About what years were you on the Raritan & Delaware Bay road?

A. I was there in 1864 and 1865.

5. Q. On said Raritan & Delaware Bay road, did you have anything to do with any other department than the repair-shop?

A. I had charge of all the departments of wood work on the road.

6. Q. About what year was it that you commenced being employed on railroads?

A. 1855.

7. Q. What railroad did you go on to at that time?

A. The Camden & Atlantic.

8. Q. Please state whether your various employments upon railroads have enabled you to become familiar with the operation and effects of the brakes used upon railroad cars.

A. Yes, sir.

9. Q. Will you please state what kinds of car-brakes you have seen in practical use.

A. In the first place, the single brake on a single truck; then comes the single-lever brake, double connected; then the Hodge; that is all.

10. Q. Have your various employments upon railroads led you to
observe the effects upon the car-wheels by the application of the
1736 brakes to them; and, if yea, please state what kind of brakes it
is the effects of which you have noticed.

A. Yes, sir; the effects of the single-acting brakes to slide the wheels, and of course "flatting" them. No effects ordinarily of any other kind of brake such as that.

11. Q. Which kind of brake wears or "flats" the wheels the least, the single-acting brake or the double acting?

A. The double acting.

12. Q. Will you please state from your railroad experience about how much longer, in your judgment, the car-wheels will last without "flatting" when the double-acting single-lever brake you have spoken of is used, than they will under the same cars and under the same circumstances, if the single brake is used?

A. About, I should say, three to one in favor of the double-acting brake. The single brake would wear out three sets to one with the double-acting. I have known with the single-acting brake the wheels to wear out in two hundred miles—two hundred consecutive miles.

13. Q. Take railroad passenger-trains as they are run at the present day, and state whether, in your judgment, they could be run with safety with only the single-acting brake?

A. No, sir.

Cross-examined by M'r Whipple:

1. Cross q. In what year, and on what road, did your experience with brakes first commence?

A. In 1856, on the Camden and Atlantic.

2. Cross-q. What brakes were then in use on the passenger-cars of that road?

A. They were then using both the single-acting and the double-acting.

3. Cross-q. What double-acting brake?

A. The single lever.

1737 4. Cross-q. What brakes were then used on freight cars?

A. Single acting.

5. Cross-q. About how long, according to your best judgment, do wheels last on freight-cars, when used under the single brake?

A. That would be a hard matter to answer, on account of the mileage.

6. Cross-q. How much longer will wheels last under freight-cars without brakes than with brakes—that is, single brakes on one end and no brake on the other truck?

A. I suppose three times as long. On a freight-car the brakes are not applied to every wheel in stopping a train. There seems to be a discrepancy in the two statements in regard to the wear of wheels on passenger and freight-cars, but in giving my testimony I take into consideration the fact that the brakes are not so long applied, nor so generally, in a freight-train as in a passenger-train.

7. Cross-q. Is it not usual to begin the application of brakes on a freight-train much further from the station where the train is to stop than in a passenger-train?

A. Not on the average.

8. Cross-q. On what roads, and at what time, did your experience with regard to the use of brakes enable you to come to the opinion that you have given with regard to the comparative wear of wheels under the single and double brake?

A. On the Raritan and Delaware Bay road, in 1864 and 1865.

9. Cross-q. Was that company at that time using single brakes on their passenger-cars?

A. Yes, sir.

10. Cross-q. To what extent?

A. On about one-half their cars.

11. Cross-q. What brakes were they using on the other half?

1738 A. The single-lever double-connected brake and the Hodge.

12. Cross-q. Did you keep an accurate account of the number of miles run by cars having the single brake, and also the double brake?

A. No, sir.

13. Cross-q. Did you keep an account as to the wear of wheels used under the single brake and the double brake, so as to enable you to come at a correct opinion as to the comparative wear of wheels under the two brakes?

A. Yes, sir.

14. Cross-q. In what way was that account kept?

A. It was kept only in my memory. When I spoke of not keeping accurate account, I mean book-account.

15. Cross-q. You say, I have known with the single brake wheels to wear out running two hundred miles. May not this have been the case without supposing they were spoiled by the brakes, and may it not have been accounted for by some defect in the "chill" of the wheels?

A. I could account for it only on account of the sliding of the wheels.

16. Cross q. Do not wheels give out in running very short distance sometimes, that have not been under brakes at all?

A. Very seldom, indeed, in my observation.

17. Cross-q. Did you ever know wheels to be slid when used under the double brake?

A. Yes, sir.

18. Cross-q. Is not the effect the same when slid under the double brake as when slid under the single brake?

A. Yes, sir.

19. Cross-q. Is there any way known to you whereby you can diminish the leverage on a single brake so as to, in a measure, prevent the sliding of the wheels?

1739 A. No, sir; and permit the brakemen to have control of the train.

20. Cross-q. Is it necessary that the brakeman should slide the wheels in order to control the train with a single brake?

A. No, sir. The reason they are slid by the brakeman is because they generally apply all their physical strength. I am now speaking of the average brakeman.

21. Cross q. Could you not diminish the size of the windlass-wheel by which the brakeman applied the power to the brakes so that he could not, even if he laid out all his strength, put any more power on one truck with the single brake than he could on each of the two trucks with the double brake having the ordinary sized windlass wheel?

A. Yes, sir; you could put any amount of power you want to on a wheel, whether effectually or not.

22. Cross-q. Are double brakes of any kind used on the freight-cars of any road or roads with which you have been connected?

A. No, sir.

23. Cross q. Do you deem it important that freight cars should have double brakes on them?

A. Yes, sir.

24. Cross-q. How do you account, then, for the companies which you have served so regardless of their own interests in not applying double brakes to freight-cars, if the saving is so great on wheels as you have testified in your direct examination?

A. I judge that is owing to blindness of the companies.

25. Cross-q. How many brakemen did they employ on a train when they used the single brake?

A. There is a difference in roads. The average would be about one man to two cars.

26. Cross q. What was the average where the double brake was used?

A. They would use about one-third less brakemen.

1740 27. Cross-q. In the running of trains of from three to five cars do they use more than two brakemen in either case?

A. I have known them to use three brakemen, the baggage-master being counted, and the conductor, too, sometimes; that would make four brakemen with the single brake—two brakemen on the pay-roll. With the single brake the baggage-master and conductor would brake, whereas with the double brake they wouldn't. Generally it requires all the available force with the single brake. I am speaking now ordinarily.

28. Cross q. In the use of the single brake was it or not customary for the engineer to reverse his engine in order to stop at the proper place at a station?

A. I have never known such to be the case unless to prevent accident.

29. Cross-q. Has it come within your observation in the use of the single brake, that there was any difference in the wear of the journal brasses compared with the wear of the brasses when used under the double brake?

A. Yes, sir.

30. Cross-q. What knowledge have you on that point?

A. There is more wear in the use of the single brake, because there is generally more power applied, and the wear is on the side of the brasses. With regard to the economy of the brasses, I couldn't say it was of so great moment. There will be some wear, but I never looked on that as of any great account.

Redirect:

14. Q. Do you know what kind of brake is in use on the freight-cars of the Pennsylvania Central Railroad?

A. No, sir.

JOHN P. RAY.

1741 H. B. MILLIKEN, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. H. B. Milliken; age, forty-eight; residence, New York City; locomotive engineer by occupation.

2. Q. How long have you been an engineer, and where have you been employed as such?

A. About twenty-eight years; on the Boston & Fitchburgh, the Vermont and Massachusetts, the New Haven Railroad, and the Hudson River road, where I am now employed.

3. Q. Please state, if you know, what kind of brakes were used on the passenger trains of the different roads where you have been employed?

A. On all the roads I was employed on till I came on the Hudson River, they were using then what they called the single-acting brake, and till some time after I came on the Hudson River they were using the single brake. I came to the Hudson River road the first of Jan-on uary, 1852.

4. Q. Was there any change made in the brakes on the passenger-cars of the Hudson River road after you came there; if so, what change?

A. There was—some time in the same year, along towards fall—putting a double-acting brake.

5. Q. About how long before they got the double brake on all their passenger-cars, as near as you can remember?

A. I think they didn't get the double brakes on them all till the later part of 1853.

6. Q. While you were running on the Fitchburgh road and the Vermont and Massachusetts road, what, if anything, did you do in stopping the trains at stations?

A. What they didn't stop with the brakes I stopped with the locomotive.

7. Q. How did you stop with the locomotive?

A. By reversing my engine.

1742 8. Q. About how often did you reverse your engine at stations on an average?

A. Well, it became a general practice to reverse the engines at stations. Two-thirds of the stations we would have to reverse.

9. Q. How was it when you went on the New Haven road as to reversing at stations?

A. Well, it was about the same there. I didn't run passenger-trains much there. I ran freight most of the time there; was sometimes taken off and run on passenger trains.

10. Q. How was it with regard to reversing your engine the first year you were on the Hudson River road?

A. At first, with the single brake, we had to reverse very often, about the same as on the other roads.

11. Q. After the double-acting brake went into use on the Hudson River road, did you have to reverse your engine to aid in stopping the trains; and if so, about how often?

A. It was so seldom that we had to do it that it would be impossible to make any estimate of it. We never hardly had to do it unless stopping at a water station when we were going very slow, and wanted to make an almost instantaneous stop, or we sometimes reversed just to take up the slack of the trains at the water stations; as to stopping at the stations, we very seldom had to do it. When the brakemen were well posted we never had to do it even to stop at the water stations.

12. Q. About how many years in all were you engaged in running on the Fitchburgh, the Vermont and Massachusetts, and the New Haven roads, before you came on the Hudson River?

A. Between five and six years.

13. Q. About how much time on each one of them, as near as you recollect?

A. On the Fitchburgh about four years, the Vermont and Massachusetts about seven months, the New Haven about the same.

1743 14. Q. How many years in all have you been engaged in running as locomotive engineer on the Hudson River road?

A. Twenty years next January.

15. Q. Please state what effect it has upon an engine to reverse it under headway?

A. It has a very injurious effect in sucking ashes and cinders down into the valves and cylinders—cutting the valves and steam-chest. And I have seen the main rods and crank-pins taken right out of an engine, in reversing an engine—broken.

Cross-examined by M'r Whipple:

1. Cross-q. How many cars, as a general rule, made up a train on the Fitchburg road?

A. About five cars.

2. Cross-q. How many brakemen were employed on such trains?

A. Two brakemen and a baggageman. In those times the baggageman most always broke, and the conductor also broke in those times. We also used to brake on the tender; we don't ever brake on the tender now—to stop at stations.

3. Cross-q. In the application of the single brake to the cars of the Fitchburgh road, was the brake applied to one truck of the cars or to both trucks?

A. They had a single brake on each end.

4. Cross-q. Could not two brakeman, baggageman, and conductor control a train of four or five cars with the single brake—a fireman using the brake on the tender—do as good execution in stopping the trains at stations as two brakemen would with the double brake on the same number of cars?

A. No; I don't think they could.

5. Cross-q. Please give your reasons for this answer.

A. The conductor, or any one of them, might put the brake on 1744 hard enough to slip the wheels, while another one might not put it on hard enough to do the necessary execution; while one man governing the whole eight wheels—one man is considered to apply the brake to all the wheels of two cars—and the friction comes more regular on the wheels with the double-acting brake.

6. Cross-q. Could not the necessity of reversing the engine to stop the train at stations where the single brake was used be obviated by increasing the number of brakemen—giving one brakeman to each car?

A. It could be obviated, but the result wouldn't be the same. We would say, for instance, take a car that is loaded and an unloaded car, and put the two together, the brakeman applying the brake upon the unloaded car, and the unloaded car would be apt to slide the wheels on the car that was not loaded, for it would be natural for him to put the brake on with the same pressure as on the loaded car; and the wheels of an unloaded car will slip quicker than the wheels of a loaded car.

7. Cross-q. Is not the same remark true with regard to the double brake?

A. In putting the double brake on an unloaded car the pressure would be so uniform that you wouldn't be so liable to slip the wheels on the two trucks as he would on the one single one.

8. Cross-q. How does the weight of passenger cars compare—those used on the Fitchburg road, in 1850, and those used now on that and other roads?

A. The cars at the present time are nearly two-thirds heavier than they were at that time.

9. Cross-q. Would it not take nearly or quite as much power to brake one truck of a car at the present time with the single brake, as it did to brake both trucks of a car with the double brake in 1850, the leverage being the same in both cases?

A. To answer that, yes or no, wouldn't be proper. I consider the effect would be just the same on a heavy car, as regards the ap-
1745 plication of the two brakes; that is, the labor of applying them, as it would on a light one; but if the same power is applied to a light car as to a heavy one, the light car will stop first.

H. B. MILLIKEN.

SATURDAY, *Oct. 14th*, 1871.

LUKE F. TRONSON recalled on behalf of the complainant:

1. Q. You testified here, a few days ago, that your occupation was that of a machinist, and that you were in the employ of the Morris & Essex division of the Delaware & Lackawanna Railroad; please state in what department of said Morris & Essex division you are employed as a machinist.

A. In the locomotive department. I am master-mechanic of the Morris & Essex division of that road.

2. Q. How long have you been master-mechanic on that road?

A. Including the time both before and since the Morris & Essex has been a part of the Delaware & Lackawanna Railroad, I have been master-mechanic of that road since February, 1856. Before that time I was foreman in the machine-shop of that road from 1850 to 1855, when I was absent for a few months, after which time I returned and took entire charge of the locomotive department of the road.

3. Q. As master-mechanic in charge of said locomotive department, what duties do you have to perform?

A. Superintend all their shops, keep all their engines in repair—see that they are kept in repair.

1746 4. Q. State whether these duties necessarily make you familiar with the details of engine construction and repairs, and with the results of accidents or injuries which happen to locomotives in the ordinary operation of a railroad?

A. Yes, sir.

5. Q. State whether you know what would be the effect upon a locomotive engine of reversing it frequently under headway; and, if so, please state what such effect would be. Answer fully.

A. Yes, sir; I do know. The effect is very often disastrous. In the first place, when you reverse an engine you pump the air into the exhaust-pipe, and down through the steam-chest and cylinder; sometimes bursting a steam-chest, and sometimes bursting a steam-pipe or blowing out a cylinder-head; it also draws or sucks ashes and cinders down into the steam-chest and cylinder, and cuts them, and also cuts the steam slide-valve and its seat; also, in reversing, there is a sudden reaction all through the engine, which strains it and racks it in every part, often starting the flues leaking and thereby damaging the boiler for the purpose of making steam; you can't make steam with leaky flues very well; it also strains and tends to injure the whole engine. I have known an engine to start out of the shop perfectly tight, and to come in after one trip, when she had been suddenly reversed, leaking like a riddle—leaking so bad that she wasn't fit to go out again without repairs.

6. Q. Please state how often, if at all, the engines running on passenger trains, on said Morris and Essex division, are reversed under headway, nowadays.

A. Not very often. Never, without it is to save life or avoid accident.

7. Q. About how much longer, in your judgment, will an engine last, if it is not reversed under headway any oftener than engines are at the present day on said Morris and Essex Railroad, as compared with
1747 the length of time it will last if it were reversed under headway on passenger trains frequently—say half the time?

A. Full one-third longer, and I think more than that.

8. Q. About how much more, if any more, do you think it would cost for the yearly repairs and injury to engines running on passenger-trains and reversed under headway as often as, say, half the time as compared with the cost of yearly repairs of the same engines under the same circumstances, but running on trains using double brakes?

A. Taking into consideration the liability to blow out cylinder-heads and steam-chests, and the other injuries I mentioned, I think it would cost from seven hundred and fifty to fifteen hundred dollars more per year per engine.

9. Q. State whether, in your judgment as a practical railroad man, it would be safe to run railroad passenger-trains as they are run at the present day—using single-acting brakes instead of double-acting.

A. I do not think it would; or, if they ran them safely, they would have to run them a great deal slower than they do now.

LUKE F. TRONSON.

Adjourned to Oct. 25th, 1871.

WEDNESDAY, *Oct. 25th*, 1871.

PETER M. DE CAMP, being duly called and sworn on behalf of the complainant, testified as follows:

Q. What is your name, age, residence, and occupation?

A. Peter M. De Camp; age, fifty-three; residence, Elizabethport, New Jersey; occupation, locomotive engineer.

1748 2. Q. On what railroad or railroads have you been employed as engineer?

The New Jersey Central; and I was on the Long Island road about three months.

3. Q. Do you remember about what year it was that you went on to the New Jersey Central as engineer?

A. I commenced on the New Jersey Central before the track was laid—in 1838.

4. Q. Do you remember about how long you remained on the New Jersey Central as engineer?

A. I have been an engineer running on the road a little over twenty-five years.

5. Q. Are you running on any railroad as engineer at the present time?

A. No, sir.

6. Q. When you first commenced running on the New Jersey Central as engineer, after the track was laid, what kind of trains did you run on?

A. On passenger-trains.

7. Q. On these passenger-trains, when you first began to run on said road, what kind of brake was used?

A. They were using the single brake then.

8. Q. In running these trains which used the single brake, did you as engineer have to do anything to aid in stopping the trains at stations; if so, what did you do?

A. Yes, sir; I had to reverse my engine. That was a general rule—to reverse the engine. We made that our practice.

9. Q. Was there at any time while you were running on said road as locomotive-engineer any change made in the brakes used on the passenger-trains; if so, what kind of brakes did they change to?

A. There was; they changed to the double brake.

10. Q. After the double brake was put on, how much of the time, if at all, did you have to reverse your engine in order to stop at stations?

1749 A. It was very seldom, unless it was from the carelessness of the brakeman not doing his duty.

11. Q. You have said you ran as locomotive-engineer on the Long Island Railroad about three months; what kind of trains did you run on this road?

A. On passenger-trains.

12. Q. What kind of brake was used on the cars in these trains at that time on the Long Island road?

A. They used single brakes at that time.

13. Q. When running these passenger-trains on the Long Island road, did you as engineer have to do anything to aid in stopping the trains at stations; if so, what did you do?

A. We used to reverse our engines very often.

14. Q. About how much of the time did you have to reverse your engine to stop at stations on said road?

A. Well, I should think it was all of two-thirds of the time, as near as I can recollect.

15. Q. Which will run the longest without having to be sent into the shop for repairs—an engine which is reversed under headway as often as you used to have to reverse engines when the single brake was used, or an engine which is reversed no oftener than is necessary when the double brake is used?

A. The one that is run with the double brake will wear the longest.

16. Q. About how much longer do you think the engine run with the double brake will last without being sent into the shop for repairs than the same engine would last run with the single brake?

A. Well, I should think there would be about one-third difference.

Cross-examined by M'r Whipple:

1. Cross-q. When they used the single brake on the New Jersey Central road, was it applied to both trucks of the car or to only one truck?

1750 A. There was one on each end—applied to each truck separately.

2. Cross-q. How many brakemen were employed on a train at the *the* time you were engineer—at the time they used single brakes?

A. It was a good deal owing to the number of cars. If we had two or three cars, we would have one brakeman besides the baggage-master; when we had four or five cars, we would have two brakemen besides the baggage-master.

3. Cross-q. Do you think, as a general rule, there would have been any necessity for reversing the engine in order to stop at stations had there been more brakemen employed on the trains—with the single brake?

A. There would, with the single brake.

4. Cross-q. Suppose there had been a brakeman to each car, on an average, do you think there would then have been any necessity for reversing the engine to stop at stations, with the single brake?

A. I think there would be a necessity for reversing the engine.

5. Cross-q. Were a brakeman employed at each single brake of the train, do you think there would still be a necessity for reversing the engine in order to stop at stations properly?

A. I think there would.

PETER M. DE CAMP.

Lewis Elder, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Lewis Elder; age, forty-three; residence, New York; occupation, locomotive engineer.

1751 2. Q. On what railroad or railroads have you been employed as engineer?

A. On the Hudson River, the New York & Harlem, the Philadelphia, Wilmington & Baltimore, and the New York & Erie.

3. Q. About what year did you commence running as locomotive engineer on the Hudson River road; about what year on the Harlem; about what year on the Erie; and about what year on the Philadelphia, Wilmington & Baltimore?

A. I commenced on the Hudson River road in 1851; on the Harlem, I think, the latter part of 1854, and returned to the Hudson River in 1857. I was on the Erie two years—1864 and 1865. I was on the Philadelphia, Wilmington & Baltimore only a short time. Left there to go to the Erie. I am running at the present time on the Harlem road.

4. Q. During the first part of the time you ran as engineer on the Hudson River road, what kind of trains did you run on?

A. I ran on passenger-trains in 1852.

5. Q. What kind of brakes were used on the cars in those passenger-trains at the time you ran them?

A. Single brakes at first.

6. Q. What kind of brakes afterwards?

A. Double.

7. Q. At the time you ran those trains with the single brake, did you, as engineer, have to do anything to aid in stopping the trains at stations; if so, what?

A. Yes; we used to have to reverse often—reverse the engine.

8. Q. About how much of the time did you have to reverse?

A. I should judge one-third, or more.

9. Q. After the double brake came to be used on said road, how much of the time, if at all, did you have to reverse in stopping at stations?

A. Scarcely any.

1752 Cross-examined by M'r Whipple:

1. Cross-q. Would there have been, in your judgment, a necessity for reversing the engine as a general thing to stop the train at stations when the single brake was used, had there been a brakeman employed, on an average, for every car on the train?

A. I think there would.

2. Cross-q. How many cars, on an average, should you judge there were run in a train after the double brake was introduced?

A. I could only say about the trains I run; there were different numbers, from six to nine.

3. Cross-q. How many brakemen were there employed on such trains when the double brake was introduced?

A. Three, I believe, to the best of my recollection.

4. Cross-q. How many brakemen were employed on the same trains when the single brake was used?

A. I think the same, and the baggage-master in addition.

5. Cross-q. Suppose a brakeman had been employed to operate each single brake in a train—there being a brake on each end of each car—do you think, in such case, there would have been a necessity for reversing the engine to stop at the proper place at stations?

A. That would have been an equivalent to the double brake if the brakemen applied the brakes with judgment so as not to slide the wheels.

6. Cross-q. Do brakemen ever slide the wheels with the double brake?

A. Seldom; they can slide them, but it is their orders not to.

7. Cross-q. Do brakemen always obey orders in this respect?

A. Not always.

1753 Redirect:

10. Q. Do the brakemen need to slide the wheels with the double brake as a general thing in order to stop trains?

A. As a general thing they do not.

11. Q. Which is more likely to slide the wheels under ordinary circumstances, the single brake or the double brake?

A. The single.

12. Q. Taking brakemen as they are ordinarily found on railroads, and suppose two of such brakemen to be stationed on a car—one at each end—would or not those two brakemen be likely, under ordinary circumstances, to slide more or less of the wheels if the single brake was used?

A. Yes, sir.

13. Q. Taking one of these brakemen and the same car, would he or not be likely, under ordinary circumstances, to slide the wheels if the double brake was used on that car?

A. No. In fact, I have seen two brakemen on a double brake and then not slide the wheels. It depends, you know, a great deal whether the car is loaded or empty—an empty car will slide a good deal easier than a loaded car. This applies the same to single brakes as double brakes.

14. Q. Now, suppose a brakeman had been employed to operate each single brake—one on each end of each car—in the single-brake trains you ran on the Hudson River road in 1852, and they had slid the wheels as you have just stated two brakemen to a single-brake car, under ordinary circumstances, would do—would it or not have been necessary to reverse the engine to aid in stopping the trains at stations?

A. It would on that road and at their rate of speed.

1754 Recross:

8. Cross-q. You mean by this, do you, that with a train of five cars and ten brakemen—one to each single brake—there would be a necessity in view of the speed run on the Hudson River road, to reverse the engine to stop properly at stations?

A. There would, oftentimes, at the speed they run at that time.

LEWIS ELDER.

JAMES B. WILSON, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. James B. Wilson; age, forty-one; residence, Newark, New Jersey; occupation, locomotive engineer for twenty-one years.

2. Q. On what railroad or railroads have you been employed as engineer?

A. On the Baltimore and Ohio Railroad, the Scranton Railroad, the New York and Erie road, the Buffalo and Rochester road, the Indianapolis and Terre Haute road. I am now on the New Jersey Central, running from Jersey City to Newark.

3. Q. In about what year did you commence to run as engineer on the Baltimore and Ohio road?

A. Nineteen years ago—somewhere about there, less or more. I ran there three years.

4. Q. When you ran there, what kind of trains did you run on?

A. Passenger-trains, freight-trains, and coal-trains.

5. Q. On the passenger-trains you ran there what kind of brake was used?

A. The single brake.

1755 6. Q. Did you as engineer have to do anything to aid in stopping these single-brake passenger-trains at stations; if so, what?

A. I had; reverse my engine.

7. Q. About how much of the time did you have to reverse your engine on these trains?

A. Every time we stopped; it would depend on what speed we were going.

8. Q. Taking the ordinary speed at which those trains were run, how much of the time did you have to reverse to aid in stopping the trains at stations?

A. Every time.

9. Q. Did you ever, on any of the roads you have been employed on as engineer, run on the passenger trains which used the double brake?

A. I have. I run with the double brake now.

10. Q. In running such double-brake trains, how much of the time, if at all, do you have to reverse your engine to aid in stopping trains at stations?

A. Not at all.

11. Q. What is the effect upon an engine of reversing on passenger trains to stop at stations?

A. A great deal of damage to the machinery.

12. Q. Please state some of the ways in which it damages an engine.

A. It damages the boiler; it strains it. It damages the packing and the valves. It damages the driving-wheel boxes; it is a great strain on them every time you reverse. In fact, it damages all the working parts of the engine.

13. Q. In your judgment, how much more would it cost in a year to repair an engine which was reversed under headway as often as would

be necessary on passenger trains using the single brake than it would to repair the same engine on the same trains if the double brake was used?

A. From one to two thousand dollars.

(Cross-examination waived.)

JAMES B. WILSON.

1756 HUMPHREY JACKMAN, recalled on behalf of the complainant.

1. Q. Please state what have been your opportunities for becoming practically familiar with the construction and operation of locomotive engines, both while you were on the Concord & Nashua Railroad, and since you have been on the New Jersey Central. Answer fully.

A. My opportunities have been from repairing and keeping engines in running order on each of those railroads. It has always been my business till the last year.

2. Q. For about how many years would this make it that it has been your business?

A. About thirty years; twenty-eight to thirty.

3. Q. While you were on the Concord & Nashua road, did the engineers running the passenger trains which used the single brake, have to do anything to aid in stopping the trains at stations; if so, what?

A. They, as a general thing, reversed their engines.

4. Q. How did you become acquainted with the fact that they had to reverse their engines?

A. By being out considerable on the road, and by remarks made, and by repairs on the locomotives caused by reversing.

5. Q. Can a man, accustomed practically like yourself to the repairing and keeping in running order of locomotive engines on railroads, tell from the condition of an engine coming into the shop for repairs whether it has been reversed under headway frequently?

A. I should think he could.

6. Q. Will you please state what is the effect upon an engine of reversing it under headway frequently?

A. It would be to loosen the braces from the boiler and frame; cause the cylinders to loosen from the fire-box and frame. It is liable to draw in cinders and ashes into the steam chest, causing the valve to
1757 destroy the valve seat and the piston to wear out the cylinder
faster; liable to blow off the steam chest and to blow out the cylinder heads; also liable to break the piston from the piston rod, and in that case the cylinders are liable to be broken to pieces and destroyed; and it is liable, and frequently causes, the flues to leak; it also causes what we call a "pound," a lateral motion in the driving boxes, the boxes of the driving wheels, and an impairing of all the running gear, from the sudden motion.

7. Q. In passenger trains using the double brake, how much of the time, if at all, do the engineers have to reverse their engines to stop at stations?

A. So far as my knowledge goes, they do not reverse their engines to stop except in cases of danger.

8. Q. About how much more, if any more, do you think it would cost for the yearly repairs and injury to engines running on single-brake passenger trains and reversed under headway as often as you say they had to reverse on the Concord and Nashua road, or as, under ordinary circumstances, engineers of passenger trains would have to reverse to

stop at stations, as compared with the cost of yearly repairs of the same engines under the same circumstances, but running on trains using double brakes?

A. Well, I should think somewhere from eight hundred to fifteen hundred dollars a year, or for thirty thousand miles run.

9. Q. About what is the average yearly mileage of locomotive engines, under ordinary circumstances, on passenger trains?

A. Twenty-five to thirty thousand miles.

10. Q. When you kept the mileage accounts of engines on the New Jersey Central Railroad, as you testified at page 74 of this record, how long did it take the engines to run forty thousand miles, on the average?

A. A year to a year and a half. They would hardly ever go over thirty thousand miles a year.

(Cross examination waived.)

HUMPHREY JACKMAN.

1758 Edwin Jones, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Edwin Jones; age, forty-three; residence, New York; occupation, locomotive engineer,

2. Q. On what railroad or railroads have you been employed as locomotive engineer?

A. Only the New York and New Haven road. I have been locomotive engineer for nineteen years, running on that road.

3. Previous to your becoming locomotive engineer on said road, did you act as fireman on any railroad or railroads; if so, what road or roads?

A. The New Haven road, and on the Hartford and Springfield, and also for a while on the Western Railroad, now the Boston & Albany.

4. Q. For about how long were you fireman on the Hartford and Springfield road, and how long were you fireman on the New Haven road before you acted as engineer?

A. I was fireman on the Hartford and Springfield about fourteen months, and a year and a half on the New Haven road before I became engineer.

5. Q. Upon what kind of trains were you fireman on the Hartford and Springfield road and on the New Haven road?

A. Passenger trains on both roads.

6. Q. What kind of trains are you now running on the New Haven road?

A. Passenger trains.

7. Q. About what year did you first commence to run as engineer on passenger trains on the New Haven road?

A. It was in the summer of 1852.

8. Q. When you ran as fireman on the passenger trains on the Hartford and Springfield road, and on the New Haven road, what kind of brakes was used on the cars in said trains?

A. The single brake.

1759 9. Q. When you first commenced to run as engineer on the New Haven road on passenger trains, what kind of brakes was used on the cars in said trains?

A. The single brake.

10. Q. At the time these single brake passenger trains were run on said Hartford and Springfield road, and said New Haven road, did the

engineer have to do anything to aid in stopping the trains at stations; if so, what did he do?

A. He oftentimes had to reverse his engine to stop the trains—to prevent them running by the stations. This was the general practice; it used to be considered necessary for the engine to help stop the trains at stations.

11. Q. After you became engineer on the New Haven road, was there any change made in the brakes on the cars in the passenger trains; if so, what brake did they change to?

A. There was; they put on what we called the double connected brake—it broke on both trucks at the same time.

12. Q. What form of double connected brake was it which was put upon said cars at the time of this change?

A. The double brake that has a cross lever under the centre of the body of the car.

13. Q. After this centre lever double brake was introduced on the cars of this road, how much of the time, if at all, did the engines running on passenger trains there have to be reversed to aid in stopping at stations?

A. We didn't do it at all—except in cases of emergency.

14. Q. Please state what is the effect on an engine of reversing it under headway.

A. In reversing an engine you are liable to break a connection rod or crank pin, or knock a cylinder head out—you are liable to break the
cylinder when you knock the head out. I have broken a crank
1760 pin and knocked my cylinder head out reversing an engine. I
have known the works on one side of an engine to be stripped off
from reversing. When you reverse, the ashes and cinders are sucked into the valves and cylinders; it also strains the flues, causing the boilers to leak, and is liable to break the packing of the piston in the cylinder. It strains the engine in every part.

15. Q. About how much more do you think it would cost for the yearly repairs of a passenger engine which was reversed under headway as often as would be necessary, under ordinary circumstances, in trains using the single brake, compared with the yearly repairs of the same engine under the same circumstances, if the double brake was used on said trains?

A. From a thousand to fifteen hundred dollars per year—as near as I could judge.

16. Q. On these single brake passenger cars on the New Haven road of which you have spoken, how many of these single acting brakes were there on a car?

A. Some of the cars had a single brake on only one end, and I think some of them had a single brake on each end.

EDWIN JONES.

Adjourned to Thursday, Oct. 26th, at 11 a. m.

1761 THURSDAY, *Oct. 26th*, 1871.

WELLINGTON RIDDELL, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Wellington Riddell; age, forty-seven; Jersey City is my place of residence; occupation, locomotive engineer.

2. Q. On what railroad or railroads have you been employed as engineer?

A. The Long Island, the Hudson River, and the New York and Erie.

3. Q. About what year did you first commence to be employed on the Long Island Railroad?

A. 1848.

4. Q. When you first commenced on that road, in what capacity were you employed?

A. I was fireman on locomotives.

5. Q. Running on what kind of trains?

A. Mail and passenger.

6. Q. Did you run as locomotive engineer on the Long Island road at any time; and, if so, about what time did you commence to be engineer?

A. Yes, sir; I was fireman about three years, and along in the latter part of 1851 I commenced to run as engineer.

7. Q. While you were locomotive fireman on said road, what kind of brakes were used on the cars running in passenger trains there?

A. Single four wheel brake; what we call a single truck brake—braking on one truck.

8. Q. Were these single brakes used on the cars running in the passenger trains on that road after you commenced to run as locomotive engineer there?

A. Yes, sir; I don't know that they all were—after I became engineer—but the single brakes were in general use on the road when I commenced running as engineer.

1762 9. Q. When these single brakes were used on the cars running in the passenger trains on said Long Island road, did the engineer have to do anything to aid in stopping trains at stations; if so, what?

A. Invariably he had to reverse his engine. As a general thing, we used to consider reversing the engine the best brake on the train; the others were not sufficient to hold.

10. Q. At any time while you were on the Long Island road as locomotive engineer, was any change made in the brakes on the cars running in the passenger trains; if so, what kind of brakes did they change to?

A. Yes, sir; they changed to the double brake—by which they could brake at either end of the car.

11. Q. State how much of the time, if at all, you as engineer had to reverse your engine to aid in stopping the passenger trains at stations, after the double brake was introduced on that road.

A. It was rarely it ever happened after we had the double brake.

12. Q. In your judgment how much more, if any more, would the injury and repairs caused to a locomotive engine yearly, if reversed under headway as often as would be necessary if single brakes were used on passenger trains, cost as compared with the yearly repairs of the same engine under the same circumstances, if reversed no more often than is necessary when the double brake is used on the cars?

A. I should think as an average thing the difference would be from seven hundred to fifteen hundred dollars yearly; and two-thirds more labor with the single brake for the engineer and fireman.

(Cross-examination waived.)

WELLINGTON RIDDELL.

Adjourned to Friday, Oct. 27th, 1871.

1763 FRIDAY, *Oct.* 27*th*, 1871.

JOSHUA P. MARTIN, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Joshua P. Martin; age, fifty-four years; Jersey City is my place of residence; and my occupation is that of locomotive engineer.

2. Q. Upon what railroad, and in about what year, did you first commence railroading?

A. I commenced in about 1834, on the Philadelphia and Columbia Railroad, owned at that day by the State of Pennsylvania.

3. Q. In what capacity were you employed on that road when you first went there?

A. First as fireman.

4. Q. Fireman on what kind of trains?

A. On freight and passenger.

5. Q. After you were fireman on said road, in what other capacity, if any, were you employed there?

A. I was locomotive engineer.

6. Q. On what kind of trains?

A. Freight first; afterwards passenger.

7. Q. Did you go upon any other railroad after leaving said Philadelphia and Columbia road? If so, what road?

A. I did, sir. I went from there upon what was called at that day the Elizabeth and Somerville Railroad, now a part of the Central Railroad of New Jersey.

8. Q. In about what year did you leave the Philadelphia and Columbia road to go upon the Elizabeth and Somerville Railroad?

A. In about 1837; along there.

9. Q. When you went on to the Elizabeth and Somerville Railroad, in what capacity were you employed there?

A. I went there as locomotive engineer, machinist, and master-mechanic.

1764 10. Q. As locomotive engineer there, what kind of trains did you run on?

A. Freight and passenger.

11. Q. Did you go from said Elizabeth and Somerville road to any other road? If so, to what road?

A. I went from there to the New York and Erie Railroad, twenty-five years ago the day before yesterday.

12. Q. When you first went on the Erie road, in what capacity were you employed?

A. As locomotive engineer, conductor, master-mechanic, general locomotive dispatcher, and afterwards back again to engineer.

13. Q. Where are you employed as locomotive engineer at the present time?

A. On the New York and Erie road, or the Erie Railway, as it is now called.

14. Q. When you were fireman on the Philadelphia and Columbia road, and engineer on the Elizabeth and Somerville road, what kind of brake was used on the cars running in the passenger trains on said roads?

A. The first brake was what we would now call only half a brake—bore on only two wheels, with a lever to press against.

15. Q. Was there more than one of these half-brakes on a car? If so, how many?

A. Yes; as a general thing, on the eight-wheeled cars, there was one on each end.

16. Q. You say this was the first brake used on the passenger cars on these roads. What was the next brake used on said cars on said roads?

A. The next brake was a brake that broke on the four wheels of one truck.

17. Q. When you were first employed as locomotive engineer on the

Erie road, what kind of brake was used on the cars running in the passenger trains on that road?

A. The same; the one used on four wheels of one truck.

1765 18. Q. During the time these brakes acting on only one truck were used on the roads you have mentioned, did you as engineer have to do anything in running trains there to aid in stopping such trains at stations? If so, what did you do?

A. Certainly; I had to reverse my engine generally.

19. Q. You say "generally." About how much of the time, on the average, did you have to so reverse your engine to stop at stations?

A. Well, it would average five times out of six.

20. Q. Did the passenger coaches on any of the roads you have mentioned have more than one on a car of these brakes acting on one truck? If so, how many to a car?

A. They had only one to a car for a number of years. Afterwards they added a second brake to the other end of the car.

21. Q. After this second single brake was added to the other end of the car, about how much of the time, on an average, did you have to reverse your engine to aid in stopping at stations?

A. It didn't make a great deal of difference unless there was an extra man. If there was an extra man at the other brake it made some little difference. I don't think, on an average the year through, it made any difference about reversing the engine after the second single brake was added to the other end of the cars.

22. Q. After these single brakes acting on only one truck were used on the Erie road, either on one end or on both ends of the car, was there any other kind of brake used on the cars in the passenger trains? If so, what kind?

A. There was, some years afterwards, what we call the double brake.

23. Q. Please state, if you recollect, what kind of double brake was used on said Erie road among the first used there.

1766 A. The connection made was under the body of the car. The brakes were connected so that when you drew on one end it affected the brakes on both trucks.

24. Q. Do you recollect whether in any of these double brakes there was a cross-lever under the center of the body of the car?

A. I think there was. I am certain that was the first connection.

25. Q. After these double brakes having the cross-lever under the center of the car-body were introduced on the Erie road, did you still run passenger trains there as engineer? If so, about how much of the time did you, as engineer, have to reverse your engine to aid in stopping trains at stations?

A. I didn't run regularly after that; occasionally I did. I didn't reverse at all stopping at stations. Frequently I would have to blow "off brakes" to let the train run up to the station.

26. Q. Why was it necessary to blow "off brakes"?

A. For the brakemen to let off the brakes so that we would run up to the stations, and not have to let on steam to run up.

27. Q. What was the cause of the brakemen putting on the brakes so as to make this necessary?

A. Not being accustomed to the double brake, the effect of it being so sudden, they applied the brake at the same point that they did the single brake till after they became acquainted with it.

28. Q. Was there any necessity of blowing the double brakes off after the brakemen became familiar with them?

A. No; not after the brakemen became accustomed to the distance they could control the train in.

29. Q. After the brakemen became accustomed to the double brakes,
did you, when running as engineer, have to reverse your engine
1767 to aid in stopping the trains at stations? If so, about how much
of the time on an average?

A. It didn't average once in a hundred times.

30. Q. Is there any difference in the cost of yearly repairs of a locomotive engine reversed under headway as often as would be necessary in running passenger-trains having only single brakes on each end of the car, as compared with the yearly repairs of the same locomotive under the same circumstances when the double brake is used on the cars?

A. Yes, sir; there is a great deal of difference in the expense.

31. Q. For which engine would the repairs cost the most, and about how much the most would they be, in your judgment, per year?

A. The cost would be most for the engine with the single brake; I should average it at fifteen hundred dollars a year.

32. Q. On the roads on which you have been employed, did you have opportunities of observing whether the application of the single brakes wore the wheels? If so, what opportunities did you have?

A. Oh, yes, I had opportunities from observation and having charge of the wheel department.

33. Q. After the double brakes were introduced on the Erie road, as you have stated, did you have opportunities for observing how the wheels lasted then?

A. I had opportunities from observation where they were taking them off and putting them on.

34. Q. Which lasted the longest, the wheels with the single brake or the wheels with the double brake?

A. Those with the double brake.

35. Q. Taking a passenger-car under ordinary circumstances, would
there, in your judgment, be any more sets of wheels required for it in a
year if it had a single brake than if it had a double brake; and,
1768 if so, how many sets do you think would be needed for the single-brake car as compared with the double-brake car in a year?

A. I should think it would take about three sets for the single-brake car to one with the double—three to one.

36. Q. Will you please state some of the effects produced upon an engine by reversing it frequently under headway.

A. Well, blowing off cylinder-heads, breaking joints, starting flues to leaking, suction of air through the exhaust-pipe, carrying the sparks and sand into the steam-chest, causing the valves to cut very fast, and the seats of the valves; throwing the driving-wheels out of quarter, tearing the pins, breaking side-rods, breaking pedestals, and frequently the frame of the engine, throwing it off the track.

37. Q. Suppose the double brakes were taken off of passenger-cars at the present day, and single-acting brakes substituted for them at each end of the cars, could or not, in your judgment, such trains be run with safety?

A. No, sir, they could not be run with safety at the time-table speed they are run now.

38. Q. Will you please state what was the average weight of locomotive engines for passenger-trains just previous to the time the double brake was introduced into use as you have stated?

A. Well, from twenty to thirty tons.

39. Q. State what road these engines were run on.

A. The Erie Railway.

40. Q. What is the average weight of locomotive-engines run on that road now, on passenger-trains?

A. From thirty to forty tons.

Cross-examined by M'r Whipple:

1. Cross-q. In your answer to the 27th direct interrogatory, you say,
"Not being acquainted with the double brake—the effect of it
1769 being so sudden, they (the brakemen) applied the brake (that is,
the double) at the same point they did the single brake, till after
they became acquainted with it" (the double brake). Did the application of the single brake at "the point" assumed by the brakemen stop the train at the proper place at the station, generally?

A. It did not, without the assistance of the engine.

2. Cross-q. Please state whether the single brakes might not have been applied at a sufficient distance from the station to stop the trains without the aid of the engine, as a general thing.

A. They could, provided the time on the time-table would have admitted of the delay of the trains in making those stops, and made our time through on the road. I claim that we would have lost probably two hours in running four hundred miles.

3. Cross-q. How many cars, on an average, composed the trains on the Erie road when the single brake was in use?

A. We would average about five, I should judge.

4. Cross-q. How many persons were employed to operate the brakes on such trains of five cars?

A. A brakeman to a car.

5. Cross-q. Were the brakes of all the trucks, or nearly all, applied either by brakeman, baggage-man, or conductor?

A. As a general thing they were.

6. Cross-q. Am I understand that under these circumstances—that is to say, when all the brakes of a train of five cars were applied at the proper time, you were obliged, in addition to this force, to reverse your engines five cases out of six, in order to stop properly at stations on the Erie road?

A. Yes, sir; to make time.

7. Cross-q. When the double brake was applied to the same train of five cars, were there any more trucks brought under the brakes than when the single brake was used?

A. I think not.

1770 8. Cross-q. What difference, if any, does it make in stopping
a train whether the power is applied to two trucks at a time, or
to only one truck, providing it is applied properly to all the trucks.

A. It would make a difference of half a minute.

9. Cross-q. What is your reason for this statement, in view of the fact that the brake has been properly applied to all the trucks of the train in both cases?

A. When you have got a single brake, if the brakeman applies his whole strength to the brake, and locks the wheels so they will slide—and they do not hold so well when they slide as when they are rolling slowly—where the same brakeman with the double brake has not the power to lock both trucks; as the leverage for braking has not been changed, there isn't any more leverage for the double brake than for the single.

10. Cross-q. Suppose that you, as master mechanic, was called upon by a superior officer of your road to so reduce the leverage of a single

brake as to make it an efficient brake, so far as the application to one truck is concerned, could you do it, and prevent the sliding of wheels, as a general thing, on an ordinary dry track?

A. I wouldn't be willing to take an oath that I could do it and make an efficient brake.

11. Cross-q. Waiving the oath for the time being—what is your judgment in the matter, as a master mechanic—could you or not so graduate the power of the brakeman by diminishing the size of the windlass-wheel, or increasing the size of the mandrel on which the chain is wound, that an ordinary brakeman, under ordinary circumstances, would apply no more power to a truck when the single brake is applied than to the same truck, in the same car, having the double brake applied to both trucks?

A. Yes; it could be done.

12. Cross-q. What was the usual speed of the train at the time
1771 you reversed the engine to stop it at a station, and how far would
the train run, as a general thing, after reversing?

A. I should put it at eight miles an hour, and we would go, on an average, three hundred feet after reversing.

13. Cross-q. Were the driving wheels, while passing over this three hundred feet, revolving in an opposite direction—or sliding upon the rail—and this five times out of six, in your effort to stop at all stations over a given route?

A. Well, they would be revolving the same way the train is going, for a certain distance, then they'd slide, and then you could get them to revolve in the opposite direction.

14. Cross-q. How much of this three hundred feet would they revolve in the opposite direction?

A. Well, I would say as a general thing about fifteen to twenty feet.

15. Cross-q. And was this process repeated five times out of six from station to station, owing to the incapacity of the brakes and brakemen to stop the train at the proper place?

A. Yes, sir.

16. Cross-q. Was the master mechanic, or whoever had charge of repairs on engines on the Erie road, aware of this necessity of reversing the engine as often as you state, in order to make time?

A. Yes, sir.

17. Cross-q. Was there, in your judgment, no remedy for this reversing of engines except in the application to the cars of double brakes—that is to say, could not the leverage have been so graduated as to have still had efficient brakes so far as one truck is concerned, and the number of brakemen increased so that on an average there would have been a brakeman to each car—and so have obviated the necessity of reversing as a general rule?

A. I think not; unless you had had a wire strung through so that
every brakeman would have applied his brake at the same time.

1772 18. Cross-q. Is it necessary to have a wire strung through the
train in order that the brakeman of the train should apply the
double brake at the same time, in order to make it efficient to stop the
train without reversing the engine?

A. No, sir.

19. Cross-q. Cannot a brakeman apply the single brake in a less number of seconds than he can the double brake—there being less chain to wind up in the former case than in the latter?

A. There is not less chain to wind up.

A. The Erie Railway.

40. Q. What is the average weight of locomotive-engines run on that road now, on passenger-trains?

A. From thirty to forty tons.

Cross-examined by M'r Whipple:

1. Cross-q. In your answer to the 27th direct interrogatory, you say, "Not being acquainted with the double brake—the effect of it 1769 being so sudden, they (the brakemen) applied the brake (that is, the double) at the same point they did the single brake, till after they became acquainted with it" (the double brake). Did the application of the single brake at "the point" assumed by the brakemen stop the train at the proper place at the station, generally?

A. It did not, without the assistance of the engine.

2. Cross-q. Please state whether the single brakes might not have been applied at a sufficient distance from the station to stop the trains without the aid of the engine, as a general thing.

A. They could, provided the time on the time-table would have admitted of the delay of the trains in making those stops, and made our time through on the road. I claim that we would have lost probably two hours in running four hundred miles.

3. Cross-q. How many cars, on an average, composed the trains on the Erie road when the single brake was in use?

A. We would average about five, I should judge.

4. Cross-q. How many persons were employed to operate the brakes on such trains of five cars?

A. A brakeman to a car.

5. Cross-q. Were the brakes of all the trucks, or nearly all, applied either by brakeman, baggage-man, or conductor?

A. As a general thing they were.

6. Cross-q. Am I understand that under these circumstances—that is to say, when all the brakes of a train of five cars were applied at the proper time, you were obliged, in addition to this force, to reverse your engines five cases out of six, in order to stop properly at stations on the Erie road?

A. Yes, sir; to make time.

7. Cross-q. When the double brake was applied to the same train of five cars, were there any more trucks brought under the brakes than when the single brake was used?

A. I think not.

1770 8. Cross-q. What difference, if any, does it make in stopping a train whether the power is applied to two trucks at a time, or to only one truck, providing it is applied properly to all the trucks.

A. It would make a difference of half a minute.

9. Cross-q. What is your reason for this statement, in view of the fact that the brake has been properly applied to all the trucks of the train in both cases?

A. When you have got a single brake, if the brakeman applies his whole strength to the brake, and locks the wheels so they will slide—and they do not hold so well when they slide as when they are rolling slowly—where the same brakeman with the double brake has not the power to lock both trucks; as the leverage for braking has not been changed, there isn't any more leverage for the double brake than for the single.

10. Cross-q. Suppose that you, as master mechanic, was called upon by a superior officer of your road to so reduce the leverage of a single

brake as to make it an efficient brake, so far as the application to one truck is concerned, could you do it, and prevent the sliding of wheels, as a general thing, on an ordinary dry track?

A. I wouldn't be willing to take an oath that I could do it and make an efficient brake.

11. Cross-q. Waiving the oath for the time being—what is your judgment in the matter, as a master mechanic—could you or not so graduate the power of the brakeman by diminishing the size of the windlass-wheel, or increasing the size of the mandrel on which the chain is wound, that an ordinary brakeman, under ordinary circumstances, would apply no more power to a truck when the single brake is applied than to the same truck, in the same car, having the double brake applied to both trucks?

A. Yes; it could be done.

1771 12. Cross-q. What was the usual speed of the train at the time you reversed the engine to stop it at a station, and how far would the train run, as a general thing, after reversing?

A. I should put it at eight miles an hour, and we would go, on an average, three hundred feet after reversing.

13. Cross-q. Were the driving wheels, while passing over this three hundred feet, revolving in an opposite direction—or sliding upon the rail—and this five times out of six, in your effort to stop at all stations over a given route?

A. Well, they would be revolving the same way the train is going, for a certain distance, then they'd slide, and then you could get them to revolve in the opposite direction.

14. Cross-q. How much of this three hundred feet would they revolve in the opposite direction?

A. Well, I would say as a general thing about fifteen to twenty feet.

15. Cross-q. And was this process repeated five times out of six from station to station, owing to the incapacity of the brakes and brakemen to stop the train at the proper place?

A. Yes, sir.

16. Cross-q. Was the master mechanic, or whoever had charge of repairs on engines on the Erie road, aware of this necessity of reversing the engine as often as you state, in order to make time?

A. Yes, sir.

17. Cross-q. Was there, in your judgment, no remedy for this reversing of engines except in the application to the cars of double brakes—that is to say, could not the leverage have been so graduated as to have still had efficient brakes so far as one truck is concerned, and the number of brakemen increased so that on an average there would have been a brakeman to each car—and so have obviated the necessity of reversing as a general rule?

A. I think not; unless you had had a wire strung through so that every brakeman would have applied his brake at the same time.

1772 18. Cross-q. Is it necessary to have a wire strung through the train in order that the brakeman of the train should apply the double brake at the same time, in order to make it efficient to stop the train without reversing the engine?

A. No, sir.

19. Cross-q. Cannot a brakeman apply the single brake in a less number of seconds than he can the double brake—there being less chain to wind up in the former case than in the latter?

A. There is not less chain to wind up.

20. Cross-q. Do you now refer to the double brake now in use on the Erie road, when you say there is not less chain?

A. I do.

21. Cross-q. What double brake is now in use on the passenger-cars of the Erie road, and how are the levers arranged for operating the brakes?

A. I couldn't tell you whose brake it is. I think there is a centre leverage under the body of the car. Then there is another brake that I call a connection under the centre of the car, with chains passing through rollers.

22. Cross-q. Assume that the brake now in use on the passenger-cars of the Erie road consists of four vertical levers attached to the brake-bars of the trucks, and connected with each other by rods and to the windlasses of the car—the windlass-chain at either end having to take the slack of all the levers before the brake can be operated effectually—would it not take longer to apply such a brake to both trucks of a car than it would to take up the slack of one lever applied to one truck—which constitutes the single brake?

A. A perfect brake hung properly has no more slack to it with four levers than with one lever.

23. Cross-q. What, in your judgment, do the six-wheel passenger-coaches of the Erie Railway weigh?

A. Fifty tons. I think that is low.

1773 24. Cross-q. What, in your judgment, did the passenger-coaches
on the Erie Railway weigh when you first came on to that road?

A. From fifteen to twenty tons.

25. Cross-q. Would it not require more power to slide the wheels of a single truck with a single brake on the present fifty-ton coaches than to slide all the wheels in the twenty-ton coaches with the double brake?

A. Yes.

26. Cross-q. Then were you as master mechanic called upon to disconnect the brakes of these fifty-ton coaches and use only the single brake, would you have any trouble is so graduating the power as not to slide the wheels, as a general rule, any more than the double brake would slide them under the twenty-ton coaches?

A. There would be some difficulty in graduating the single brake on those fifty-ton coaches. It could be done—anything can be done.

27. Cross-q. It appears by your evidence that there were times when you did not reverse your engine to stop the train at stations; why not? If reversed once, twice, or more, why not always and at every stop you wished to make at stations?

A. Now, I am running and I leave Port Jervis, and I make four stops before I strike Narrowsburg. Now, the grade and the line of the road and stations were on a level and long curves. At Narrowsburg, you run in on quite a steep grade—going west—and a very sharp curve, and that would assist the brakemen to stop the train—the steep grade and sharp curve. Brakemen have generally a point where they apply the brakes.

28. Cross-q. Did the brakemen have their point near all stations where they would apply the brakes in order to stop at the proper place at the
stations, whether the single or the double brake was in use?

1774 A. I think they had about the same point. The whistling post
is about five hundred yards from the stations, and they generally make that their point.

29. Cross-q. Was there no more time given to stop the train with single brakes on the Erie road than now that double brakes are used?

A. The same post is used in both cases.

30. Cross-q. Then it was owing to the shortness of distance, was it, that you were allowed to apply the single brake in approaching the stations that you were obliged to reverse the engine in order to make time?

A. Yes.

31. Cross-q. Had you been allowed a greater distance in which to apply the single brake, would it have obviated the necessity, as a general rule, of reversing the engine?

A. Yes; but we couldn't have made our time.

32. Cross-q. What was the average time of the trains you run, including stops?

A. Twenty-five to thirty miles per hour.

33. Cross q. Could not, in your judgment, the trains on the Erie road have been stopped at stations without reversing the engine as a general thing, had the company thought proper to put a man, on an average, to each car—five hundred yards being given in which to stop—using the single brakes?

A. No; I don't think it could have been done.

Redirect:

41. Q. Which brake is most liable to slide the wheels of a car under the circumstances of average use on railroads, the single brake or the double brake?

A. The single brake is more liable to slide.

A. Why?

1775 A. Simply because the same power was applied as there is to the double brake. This power with the double brake is not enough to hold them so that they will slide under ordinary circumstances, yet there seems to be power enough in the double brake to do the work. With the single brake they had too much power.

43. Q. Suppose with the single brake they had reduced the leverage, and consequently the power—as you have testified could have been done—so that the brake would have had just power enough to stop the car without sliding the wheels under the circumstances of running on some particular day—would that brake, unchanged as to its power, have been an efficient brake on some other day, if the circumstances on such other day had required more power to be applied to the brake to stop the car than on the first day supposed?

A. I shouldn't think it would.

44. Q. Are the circumstances under which brakes are required to be applied to stop passenger trains always the same in the practical operation of railroads; or do they differ one day from another; if so, how do they differ?

A. They are not the same; there is some days a dry, clean rail—the weather is pure; other days the sun is very hot and has a great effect on the rail; other days are damp—there is moistness on the rail; and then there are variations in weight.

45. Q. Are there any differences in said circumstances as to whether the brakes have to be applied on grades, as compared with level portions of the track, and on curves as compared with straight portions of the track?

A. Yes, there is a difference, of course.

46. Q. To make a brake efficient for practical use—whether single or double—must it be adapted to stop a car without under ordinary circumstances sliding its wheels on the occasion when the force required,

1776 in view of the varying circumstances mentioned, is the greatest, or on the occasions when it is the least?

A. It must be adapted to the occasions when the greatest force is required.

47. Q. Suppose a single brake has its leverage so reduced that it is capable of exerting on its truck no more power than would be exerted by a double brake on that same truck—would it or not be an efficient practical brake under all the varying circumstances which you have mentioned?

A. No, sir, it would not.

48. Q. According to your observation, have the relative lengths of the arms of the truck levers in the double brake—or in other words the "leverage" of the double brake—been changed from the "leverage" which the single brake had?

A. No, sir.

49. Q. Would it be practically possible, as a general thing, on a train of cars having single brakes, for all the brakemen to apply the brakes simultaneously?

A. No, sir.

5. Q. If not applied simultaneously in a train having single brakes, what is liable to be the result as to more or less of the wheels of the train?

A. The train wouldn't be checked so suddenly, and they would be more liable to slide the wheels.

51. Q. Suppose the brakes of a train having *double* brakes are not all applied simultaneously, is there any reason why, notwithstanding that fact, the double brakes will still retard the train efficiently without sliding the wheels; and if so, what is the reason?

A. Yes, simply because the brakeman applies the brakes to both trucks of one car at the same time and gets the weight of that car at the same time towards stopping the train.

52. Q. Suppose the same car had a single brake on each end of it and a brakeman to each of these brakes—would these two brakemen,
1777 as a general thing, be able to apply the said brakes simultaneously, so as to get the whole weight of that car at the same moment towards stopping the train?

A. No, sir.

53. Q. Would this, as a general thing, be true of all the cars in a train—under the circumstances supposed?

A. Yes, sir.

54. Q. You have stated that passenger cars at the present day are much heavier than they formerly were; assume them to be twice as heavy now as formerly, and suppose single brakes to be put upon them, one on each end, with the same leverage which single brakes had when they were formerly used on passenger cars—would the wheels on the heavier car be as liable or more liable to slide than the wheels under said lighter car?

A. The lighter car will slide easier than the heavier one.

55. Q. If single brakes were to-day placed upon the passenger cars of to-day—one brake on each end of the car, if preferred—but with no more leverage than the single brake had when used formerly on passenger cars, would such single brakes be capable of doing efficient braking?

A. No, sir.

56. Q. Would such single brakes placed on the passenger cars of to-

day, but with no more leverage than formerly, be as efficient for such passenger cars as they were for the passenger cars of former days ?

A. I think they would not.

57. Q. Which is the easier to stop in a given time at a given speed, a car weighing ten tons or a car weighing twenty tons—relying, I mean, only on the brake ?

A. A car weighing ten tons.

58. Q. Now, of how much practical use would a brake adapted to stop only a ten ton car, under the ordinary circumstances of train running, be when used upon a twenty ton car, if the latter car had to
1778 be stopped in the same time as the former car—the speed being the same in each case ?

A. I shouldn't consider it a practical brake on a twenty ton car.

59. Q. To make it a practical brake for the twenty-ton car, would or not its leverage require to be increased proportionately to the increased weight of the car ?

A. Yes, sir.

60. Q. Then, if so increased, would or not the same consequences ensue which ensue on the ten ton car ?

A. Certainly they would.

61. Q. In your 26th cross-answer you stated that you could graduate the power of a single brake so as not to slide the wheels, as a general rule, on fifty ton coaches any more than the double brake would slide them on twenty ton coaches; would a brake which never, under any circumstances, had power enough to slide the wheels of a fifty ton coach be an efficient brake, in practical railroading, for such a coach ?

A. No.

Recross :

34. Cross q. Should you so graduate the power on a fifty ton car having single brakes as not to slide the wheels under ordinary circumstances, would such a brake, in your judgment, be an efficient brake, each brake having the power to slide wheels on a wet or frosty track, but not on a dry track ?

A. I should not think it was an efficient brake for ordinary use.

35. Cross q. Why not—since it has the elements of an efficient brake, to wit, to slide or not slide the wheels according to the condition of the track ?

A. Why, simply because you get the weight of one end of the car upon it. It is an efficient brake for one truck, but not for the whole car.

1779 36. Cross q. Now apply the same brake to the other end of the same car—and suppose both brakes to be operated simultaneously by two brakemen—would such a brake, in your judgment, be efficient in stopping the car ?

A. No; I shouldn't think it would.

37. Cross q. Please give your reasons for such opinion.

A. Both brakemen would not, as a general thing, apply the brakes at the same time, and the one applying the brake first would be very apt to lock the wheels of his truck so that they would slide; the consequence would be that that truck would slide while the other would be rolling, which wouldn't have the same effect as if both were rolling.

38. Cross-q. Suppose the brakemen did not apply the brakes so as to lock the wheels of either truck, but applied them simultaneously, would the brakes under such circumstances be efficient in stopping the car ?

A. Yes.

39. Cross-q. Now suppose the two brakemen do not apply the brakes of both trucks simultaneously into a second, or even two seconds, but nevertheless do apply them effectually without sliding the wheels, would such application of brakes be efficient, practically speaking?

A. Well, running that car alone, it would be.

40. Cross-q. Supposing more cars were run in connection with this car in the same train, and were operated in like manner, would they all be efficient?

A. They would. Of course I take it for granted now that all the brakemen on all the cars apply their brakes at exactly the same time—but ninety-nine times in a hundred it can't be done.

41. Cross-q. Are all the double brakes in a train of cars applied simultaneously throughout the train?

A. No; they are not.

42. Cross-q. Has there been a change of leverage in applying
1780 brakes to cars on the Erie road corresponding to the change in the weight of cars on that road?

A. I think not, sir.

43. Cross-q. Has there been a change in the leverage on the cars of any other road corresponding to the change in the weight of cars, to your knowledge?

A. Not to my knowledge.

Redirect resumed:

62. Q. About how much of the time practically, under circumstances as they occur on railroads, could two brakemen, one on each end of a car, apply two single brakes on that car simultaneously?

A. They might do it once out of a hundred times.

63. Q. Is it necessary, in a train of cars having double brakes, that all these double brakes should be applied simultaneously throughout the train in order to do efficient braking?

A. It isn't necessary that they should be all applied at the same time.

64. Q. Why is it that the double brake will do more efficient braking, even although the brakes are not applied simultaneously throughout the train, than single brakes will under the same circumstances?

A. They are not so liable to slide the wheels.

Recross resumed:

44. Cross-q. What advantage, if any, is derived from the simultaneous action of the brakes of both trucks by the use of the double brakes over the application of the same brake, disconnected, by two brakemen?

A. I don't see as there is any, provided you connect the two brakemen.

1781 45. Cross-q. What would be the difference provided the brakemen were not connected, but should get their brakes set thoroughly, but not so as to slide the wheels, but should differ a second or two in the time of application?

A. The difference would be some, of course, but very little.

46. Cross-q. Would it be so much as to essentially affect the stopping of the car in the quickest possible time, provided all the power had been applied to both trucks by the two brakemen that the wheels are capable of receiving without sliding?

A. It would make a trifling difference.

47. Cross-q. Would that trifling difference be of any essential importance, practically speaking, in stopping a train?

A. Yes, it would.

48. Cross-q. Why would it?

A. It is simply this: In case a train was ahead of me, probably in that second of time I could save train, engine, life, and everything else.

J. P. MARTIN.

ALBERT BRIDGES, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. Albert Bridges; age, fifty-nine; residence, Jersey City; business, railroad supplies.

2. Q. How long have you been in the business of railroad supplies, and how extensively are you engaged in it?

A. Twenty years; I have always been very extensively engaged in it.

1782 3. Q. Were you ever practically engaged in building railroad cars; if so, where, when, and for about how long?

A. Yes; at Cambridgeport, Mass.; from 1834 to 1850.

4. Q. How extensively were you engaged in building railroad cars in those years?

A. Very largely.

5. Q. What kind of brakes did you put on to passenger-cars built by you in those years, and how many to a car?

A. I put on single brakes, one on each end, braking only on four wheels at a time.

6. Q. Please state what was the average weight of railroad passenger-cars used on American railroads in those days?

A. The average weight of the first eight-wheel cars up to 1850 would average about nine tons—not exceeding eleven. We built the first eight-wheel cars which were used in New England—these we built in 1838 or 1839.

7. Q. What opportunities did you have while building cars to know the weight of cars built by other builders?

A. My opportunities were, being conversant with the construction and being often called to examine different constructions of cars; I judge from my former experience.

8. Q. What opportunities have you had in your railroad supply business, since you left off building cars and down to the present time, of knowing the weight of passenger cars used on American railroads?

A. I have always been so connected with railroads, and from my former experience, that I have often been called upon to give my opinion about the construction of cars on different railroads.

9. Q. Have these things made you familiar with the weight of passenger cars during the time referred to?

A. Yes.

1783 10. Q. What is the average weight of ordinary passenger-cars running on American railroads at the present time?

A. They will average at the present time about eighteen tons—not far from that.

11. Q. State, if you know, what is the average weight of the sleeping and drawing-room cars used upon railroads at the present time—for instance, the Pullman cars?

A. I should think the average weight of them would be about twenty-five tons, to the best of my judgment.

12. Q. State, if you know, what was the average weight of the ordinary passenger-cars on the Erie road twenty years ago?

A. I should think they were about fourteen tons.

13. Q. State, if you know, what is the average weight of the ordinary passenger-cars on the Erie Railway at the present time?

A. They will average about eighteen tons and a half—this is for their four-wheel truck-cars; their six-wheel truck-cars will weigh about twenty tons.

(Cross-examination waived.)

ALBERT BRIDGES.

1784 TUESDAY, *Nov.* 14*th*, 1871.

JOSHUA P. MARTIN, recalled on behalf of the complainant.

1. Q. In your testimony here, a few days ago, you spoke of the passenger cars on the Erie Railway weighing fifty tons. Have you any explanation to make?

A. Yes, sir. I should have said fifty thousand pounds—average weight.

2. Q. You have also spoken of the wheels sliding under the cars while using the single brakes. What, if anything, did you observe when the brakes were applied to the wheels, and the wheels were sliding upon the track?

A. As a general thing, my observation is that sparks of fire are passing from the wheels.

3. Q. What effect, if any, have you noticed on the surface of the wheel after they have been sliding on the track?

A. There appears to be a flat polished surface.

Cross-examined by M'r Whipple:

1. Cross-q. Have you noticed the operation of single brakes on the twenty-five ton cars on the Erie road?

A. I have not, to my knowledge.

2. Cross-q. What was the weight of the cars on which you noticed the effect of single brakes?

A. Well, I should judge they weighed about twelve to fourteen tons.

3. Cross-q. While the single brake might cause the sliding of wheels on a twelve to fourteen ton car, would the same brake, with the same leverage and same power applied, cause the wheels to slide on a twenty-five ton car?

1785 A. I don't think I could answer that exactly, from the fact that I have no knowledge of seeing the single brake on a twenty-five ton car.

4. Cross-q. What is your judgment in the matter inquired of, as a railroad man and mechanic?

A. Well, with regard to that, I simply judge that it would be owing to the weather and the condition of the rail—that the single brake would probably slide the wheels of a twenty-five ton car.

5. Cross-q. All the circumstances and conditions being equal, would the single brake be as liable to slide the wheels of a twelve ton car as it would the wheels of a twenty-five ton car?

A. Yes, sir.

6. Cross-q. Assume that the double brake is applied to the twelve ton car, and a single brake to the twenty-five ton car, would the brake on the former be just as liable to slide the wheels as the brake on the latter—the circumstances and conditions of the track being the same?

A. I think that the single brake would be more liable to slide the wheels than the double brake, by a brakeman using it by hand.

7. Cross-q. Is there not more weight resting on the truck to which

the single brake is applied than on both trucks to which the double brake is applied, as assumed in the preceding question?

A. There is a trifle more on the truck of the twenty-five ton car than on the two trucks of the twelve ton car.

8. Cross-q. Is it or not a law in developing friction force that the heavier the body to be controlled the more power is required to bring it to rest when in motion, all the conditions being the same?

A. Yes.

9. Cross-q. Then may not the single brake on one truck of a twenty-five ton car—all the circumstances being the same—be just as
1786 effectual in developing friction force, as a double brake on a
twelve ton car?

A. I think not.

10. Cross-q. Please give your reasons for this answer.

A. My reason is simply this; that a man drawing the single brake on, knowing that he has only got the four wheels to operate with, will use his whole strength and power, and is liable to slide the wheels, where the brakeman on the double brake, knowing that he has eight wheels to bear on, will not use his whole strength and power.

11. Cross-q. In this answer, do you take into account that the car with the double brake on weighs but twelve tons, while the one with the single brake weighs twenty-five tons, and that in both cases circumstances and conditions of the track are the same?

A. I do.

J. P. MARTIN.

Edward S. Renwick, being duly called and sworn on behalf of the complainant, testified as follows:

1. Q. What is your name, age, residence, and profession?

A. Edward S. Renwick; age, forty-eight; residence, Milford, New Jersey; I am by profession a civil and mechanical engineer.

2. Q. Have you been accustomed to the examination and comparison of letters patent and inventions; have you had opportunities for acquiring knowledge upon mechanical subjects, and if so, what opportunities; and have you frequently been examined as expert in patent causes?

1787 A. I have been accustomed to the examination and comparison
of letters patent and inventions. I was engaged in the construction and superintendence of machinery for about ten years before I became engaged in my present occupation. For the last twenty-two years I have been engaged in acting as expert in the trials of patent causes, and in soliciting patents; and during this period have had to examine a great number of patents and descriptions of machinery for performing numerous operations in the useful arts. I have frequently been examined as expert in patent causes, and for the last four or five years have frequently been called upon to testify in four cases a month.

3. Q. Have any of these cases in which you have been called as expert involved branches of railroad machinery?

A. They have.

4. Q. Have you read a certified copy of the letters patent of the United States, issued July 6th, 1852, to Henry Tanner, as the assignee of Batchelder & Thompson, and examined the drawing annexed thereto? If yea, do you understand the same and the invention therein described?

A. I have read a certified copy of the patent recited in the question, and believe I understand the invention recited therein.

A. Have you read the printed record of testimony taken in the present cause to be used before the master upon the accounting herein, as far as it has progressed, and do you understand the same?

A. I have read it, and believe that I understand it.

6. Q. Are you familiar with the construction and operation of the form of railroad-car brake known as the "single-acting brake"?

A. I was familiar with it some years ago, but I have not lately observed that form of brake in operation.

1788 7. Q. Will you look at the model now shown you and state what it represents?

A. It represents the running-gear of an eight-wheel car, with a single-acting brake applied to the wheels of each truck. The levers of the brakes of the two trucks are arranged in different ways, but the arrangements are substantially equivalent, the brake-shoes of one truck only being commanded by the brake-windlass at the adjacent end of the car-frame.

(Counsel for the defendants here admits that the model shown the witness is a correct model of two different ways of arranging what is known as the single-acting car-brake.)

8. Q. Will you state what, if anything, there is in the construction and arrangement of the single-acting car-brake which would be likely to cause the car-wheels to which it is applied to slide on the track under the ordinary circumstances of the application of car-brakes in practice?

A. In all the systems of brakes that I have seen in operation, the construction is such that a brakesman, by exerting the force which he is capable of exerting, can produce so much friction upon the wheels that they will cease to revolve, and will therefore slide upon the track. The object of a brakesman, when the signal is given to put down the brakes, is to check the movement of the train as rapidly as possible, and in doing this he will naturally exert his force as rapidly as possible until he notices that the speed of the train begins to slacken. In the single-acting system of brakes, each brakesman commanded the shoes of but four wheels, and the application of friction to them would check the speed of the train much less rapidly than the application of friction to eight wheels, as is accomplished by the double-acting system of brakes.
1789 Hence the brakesman, when operating with the single-acting brakes, would be much more likely to exert the amount of force required to stop the wheels and cause them to slide than he would when operating with the double-acting system. There may also be cases where the proportion of the brake-levers of the double-acting system, as compared with the single-acting system, is such that only half the amount of pressure can be applied to each brake-shoe of the double-acting system, as to each of the single-acting system, by the same application of force to the brake-wheel. As in such cases the force is divided up among eight wheels, instead of among four, the risk of producing sufficient friction upon any one wheel to stop its revolution, and cause it to slide, would be greatly reduced.

9. Q. In which condition of the car-wheels will they retard the motion of the train most efficiently, when they are checked by the brakes so as to revolve very slowly, or when they slide upon the track?

A. They would retard the motion of the train more efficiently when they continue to revolve under the pressure of the brakes than when they slide upon the track without revolving.

10. Q. Can you state the reason of this?

A. In my opinion, there are two reasons which affect the matter. In the first place, the effect of the sliding upon the track of the exceedingly small portion of the surface of the wheel which is in contact with it, and under the pressure of the car, is to produce an immense amount of friction upon the small surface of the wheel, and to generate intense heat; so that I have no doubt the particles of iron abraded from the wheel are softened sufficiently to act as an imperfect lubricator between the sliding surface of the wheels and the track, thereby reducing the friction so that the friction of the wheel upon the track is less than the friction of the wheel when revolving against the brake-shoe.

1790 In the next place, the effect of the sliding is to polish the surface of the wheel which is in contact with the rail, which also tends to reduce the friction.

11. Q. Assume that when the brakes are applied to the wheels with sufficient force to cause the latter to slide, sparks come from the point of contact of the wheels with the rail, what would that indicate, in your judgment?

A. It would indicate that the particles of iron abraded from the wheel are heated so intensely hot as to burn in the atmosphere; or, in other words, that they are heated to a high white-heat, when the iron is either very soft or else actually melted.

12. Q. In this condition of the iron at said point of contact, what would be the effect on the wheel as to holding the train?

A. The effect on the wheel to hold the train would be reduced, as the heated particles of iron, before their escape from between the two surfaces, would act as a lubricator to reduce the friction between the surface of the wheel and the track.

13. Q. In your eighth answer, you spoke of cases in which the proportion of the levers in the double-acting brake system, as compared with the single-acting system, may be such that only half the amount of pressure can be applied to each brake-shoe of the double brake that is applied to each shoe of the single brake by the same application of force to the brake-wheel. Will you please look at the drawing of the above-mentioned patent to Henry Tanner, and state what would be the amount of pressure exerted by the brakeman upon each brake-shoe if the rods marked "H^3" and "G^3," in said drawing, were carried out to the ends of the centre lever marked "A^1," as compared with the pressure when they are connected to said centre lever at the points represented in said drawing.

1791 A. If the rods H^3 and G^3 were applied to the ends of the central brake-lever, the brakesman could exert less than half as much pressure upon each brake-shoe as he could when the same rods were arranged as in the drawing, assuming that in each car he applied the same force to the brake-wheel.

14. Q. Will you please state what are the relative lengths of the arms of the brake-levers of the trucks, as represented in the drawing of said patent?

A. They are about as seven to twenty-two (7 to 22) in one truck, and six to twenty-two (6 to 22) in the other.

15. Q. You also stated in your eighth answer that a brakeman would check the speed of a train much less rapidly with the single-acting brake, commanding the shoes of but four wheels in a car, than he would in the double-acting system. Suppose there be one of these single brakes upon each end of a given car, and suppose a brakeman be provided at each of these single brakes, what would be the effect, as regards the tendency to slide the wheels of that car, as compared to the same car, under the same circumstances, but provided with a double-acting brake operated by one brakeman?

A. I think the presumption is, there would be a greater tendency to slide the wheels with the single brakes than with the double brake, and the tendency would be much greater to slide with the single brake if the levers of the double brake were so arranged that only about half the pressure could be exerted against each shoe as against each shoe of the single brakes, when the same amount of force was applied to the brake-wheel.

16. Q. Please look at the drawing annexed to the said Tanner patent, and also at the model which was shown you a little while ago of the single brake, and state if there is any difference in the amount of pressure that can be applied to the brake-shoes in these different forms of brakes; and, if so, in which the pressure is the greatest.

1792 A. Assuming that the brake-standards in the two cases compared and the brake-wheel are of the same dimensions, a greater amount of pressure can be exerted upon each shoe of the Tanner brake represented in the drawing than can be exerted upon each shoe of the single brake represented in the model, the same amount of force in each case being exerted upon the brake-wheel.

17. Q. Please state to what this is owing.

A. It is owing primarily to the fact that in the Tanner brake the rods H^3 G^3 are connected with the centre lever at points nearer the fulcrum of that lever than half the distance from that fulcrum to the ends which are connected with the brake-standards; so that the pressure exerted in each truck is greater than the amount of pressure exerted upon the end of the centre lever by the application of force at the brake-wheel. It is due secondarily to the fact that the proportions of the arms of the truck levers in the Tanner brake represented in the drawing differ from those of the truck-levers of the model, and the difference is in the proper direction to increase the pressure upon the brake-shoes of the Tanner brake, as compared with those of the model brake, when the same force is applied to the upper ends of the truck levers.

18. Q. Please also answer the last two questions upon the assumption that the proportions of the arms of the brake-levers in the trucks are the same in the single brake and in the Tanner brake.

A. Assuming in such case that the brake-standards in the two constructions compared and the brake-wheels are of the same dimensions, a greater amount of pressure can be exerted upon each shoe of the Tanner brake represented in the drawing than can be exerted upon each shoe of the single brake the same amount of force in each case
being exerted upon the brake-wheel. The reason is, that in the
1793 Tanner brake the rods H^3 G^3 are connected with the centre lever
at points nearer the fulcrum of that lever than half the distance from that fulcrum to the ends which are connected with the brake-standards; so that the pressure exerted in each truck is greater than the amount of pressure exerted upon the end of the centre lever by the application of force to the brake-wheel.

19. Q. Please look at the certified copies now shown you of letters patent issued to Nehemiah Hodge, October 2d, 1849, and to Francis A. Stevens, Nov. 25th, 1851, and state whether you understand the construction and arrangement of the car-brakes represented in those patents respectively.

A. I have examined the certified copies referred to the question, and believe that I understand the construction and arrangement of the car-brakes represented in each of those patents.

20. Q. Please compare the said Hodge and Stevens brakes with the single-acting car-brake, and assume that the truck-levers, brake-staffs, and brake-wheels of all the said brakes compared are of the same pro-

portions, and state in which of these brakes the pressure upon each truck is greater, if there be any difference.

A. The amount of pressure upon each truck in each of the three cases mentioned is substantially the same when the brakes are bearing upon the wheels and the same force is applied to each brake-wheel.

21. Q. Please state what difference, if any, there is in the practical effect as to stopping a railroad train between the Tanner brake, the Hodge brake, and the Stevens brake.

A. If the amount of force applied to the brake-wheel in each case be less than sufficient to stop the revolution of the wheels, there would not, in my opinion, be any material difference in the practical effect of the three brakes; but when the force exerted amounts to enough to
1794 stop the revolution of the wheels, four of the eight wheels in the Tanner and Hodge brakes would probably cease to revolve before the remaining four, while in the Stevens brake the presumption is that the whole eight would be stopped nearly at the same moment. It would also be possible with the Stevens brake to apply a little more force to the brake-wheel before any of the wheels stopped than could be applied with the Hodge brake and the Tanner brake before any of the wheels would cease to revolve. I have made this answer under the assumption that the proportions of the central levers in the Hodge brake and the Tanner are substantially the same as those represented in the drawings of the patents respectively.

22. Q. In the case of the Stevens brake, is it theory or practice that the whole eight wheels are stopped at the same moment?

A. According to theory they ought to stop at the same moment, but the presumption is that in practice the wheels of the truck that is nearer the brake-wheel upon which the brakesman operates will stop before the wheels of the other truck, because the friction of the connections will really neutralize a portion of the force tending to be transmitted to the farther truck.

23. Q. What difference, if any, is there in the construction of the parts in the trucks between the Tanner brake and the Hodge brake?

A. There is none substantially.

24. Q. What are the relative lengths of the arms of the brake-levers in the trucks in the Hodge brake, as represented in the Hodge patent before you?

A. They are about eight to eleven (8 to 11).

25. Q. Suppose a railroad train to consist of six eight-wheeled cars, each car weighing ten tons, and a second train containing the same number of cars, but each car weighing about eighteen tons. Now suppose such trains to be running at the same speed and under the
1795 same circumstances, what is the law of momentum in such case, and what are the relative amounts of force required to stop the two trains?

A. The momentums of the two trains under the same circumstances would be in the proportions of the respective weights of the cars, or as ten (10) for the lighter car, to eighteen (18) for the heavier; and the relative amounts of forces required to stop the two would be in the same proportions.

Cross-examined by Mr Whipple:

1. Cross-q. Please look at drawings in Tanner brake patent, and at model of single brake—the same as admitted by defendant to be such in this case—and state which brake mechanism, if applied to separate cars, as represented in drawings and in model, would be the least liable

to slide the wheels, the power applied to the brakes in both cases, the weight of the cars, and the condition of the track, being the same.

A. If in neither case the power applied to the brake standard is sufficient to stop the wheels, there would not be any greater liability to stop the wheels with the one brake than with the other.

2. Cross-q. Suppose the same power, under the same circumstances, were applied to the brake wheel of the Tanner brake, the mechanism being the same as represented in the drawings, and the same power applied to the brake-wheel of the single brake as represented in the model—which mechanism, all the conditions being the same, would convey the most power to the wheels in both cases?

A. Assuming that the language, "under the same circumstances," requires, among other things, that the brake-wheels and the brake standards are to be the same in the two cases, but does not require that the proportions of the arms of the brake-levers shall be changed from the proportions represented respectively in the drawing of the Tanner patent and the model, the Tanner mechanism would apply the greatest pressure to the brake-shoes of the wheels. 1796

3. Cross-q. Would that pressure, in your judgment, be sufficient to slide the wheels under ordinary circumstances?

A. As the amount of pressure is not stated in the question, it is impossible for me to give a definite answer to the question. The Tanner system and the single-brake system are each so constructed that force sufficient to cause the wheels to slide on the track can be applied in each case.

4. Cross-q. Do you deem it necessary to make any modification of the leverage as represented in the drawings of the Tanner patent in order to prevent the sliding of the wheels?

A. As I have never had occasion to keep an account of the operation of the Tanner brake on a railroad, it is not possible for me to answer the question from my own knowledge. From what I have observed of the operations of brakes on railroads and of the manner in which the brakesmen apply the brakes, I should modify the proportions of the leverage, if I wished to prevent, as far as possible, the possibility of sliding the wheels.

5. Cross-q. Have you not stated in your direct examination, that the Tanner brake, as represented in the drawings, applied to a car, would apply more pressure to the wheels of each truck than would be communicated to the wheels in the truck of the single brake, as represented in the model?

A. I have, in substance, assuming that the same force was applied to the brake-wheel in each case.

6. Cross-q. Which brake, in your judgment, would be likely to slide the wheels of a car—the Tanner, the Hodge, or the Stevens brake—the size of the brake-wheel and the power being the same?

A. If the power applied to the brake-wheel in each case be less than sufficient to cause the wheels to slide, there will be no greater likelihood of causing the wheels commanded by one brake system to slide than those commanded by either of the others. Assuming that the proportions of the brake-levers in each system are the same as those represented in the drawings of the respective patents, but that the brake-wheels and brake-standards are the same in all three, the wheels of a car having a brake on the Tanner system could be caused to slide by a less application of force to the brake-wheel than was required in the other two systems to produce the same effect. 1797

7. Cross-q. Please give your reason for the last part of your answer.

A. The reason is that the proportions of the levers as represented in the drawings of the Tanner patent are such as to give the force applied to the brake-wheel a greater mechanical advantage, as respects the application of pressure to the brake-shoes, than in the other two cases.

7. Cross-q. Assume that the proportions of the levers in each truck are the same—would this modify the latter part of your answer to the sixth cross-question?

A. It would not change the general fact, as stated, because the relative operative length of the *the* arms of the center lever of the Tanner brake as represented in the drawings of the Tanner patent are such as to give the force operating upon the brake-wheel a greater mechanical advantage over the brake-shoes than is given by the levers of the other two systems, even under the assumption that the relative lengths of the truck levers of all three are the same.

9. Cross-q. Which brake, practically, gives the more equal distribution of power between the trucks—the Tanner brake or the Hodge brake?

A. If the brake is in the best possible condition in each case, there is no appreciable difference between the two; but the Hodge arrangement permits of a considerable variation in the brake-shoes and
1798 connections, by wear or otherwise, without materially varying
the equality of distribution between the two trucks—this difference in result being due to the fact that in the Tanner system the fulcrum of the centre lever is fixed, while in the Hodge brake the fulcrums of the two cross-levers are movable, and adjust themselves to variations in the brake-shoes and in the connections.

10. Cross-q. In case the brake-shoes of a Tanner brake in one truck happen to be of a soft material, and those in the other truck of a hard material, how would such condition of the shoes affect the application of pressure to the wheels, as the brake continued in use?

A. The distribution of the pressure would be affected by a number of circumstances which are not mentioned in the question, and therefore it is impossible to give an answer which would apply to every case that the question would include. If the brakes were all carefully adjusted, the application of the pressure to the wheels of the truck having the shoes of soft material would be precisely the same as that to those of the truck having the brake shoes of the hard material, but what would take place after the first application of pressure it is impossible for me to state. It might turn out that the harder shoes would in fact wear faster than the softer shoes, with the same pressure, or might wear slower. In the former case, after wear commenced there would probably be less pressure upon the wheels of the truck having the harder shoes than upon the wheels of the other truck; and in the latter case there would probably be more pressure. How much less or how much more pressure there would be, I cannot say, as I should have to experiment upon the materials of which the shoes were composed so as to find the law of their wear under the circumstances occurring in practice, in order to enable me to answer the question.

1799 Redirect:

26. Q. You have stated in the cross-examination that with some forms of the double brake the pressure applied to the brake-shoes in each truck is the same as in the single brake, and that with one form it is greater, the proportions of the truck levers, as you have said, being assumed to be the same in all the cases. The witnesses who have testified thus far in the case state that when the single brake was employed

on cars it was a very frequent thing to slide the wheels, and that with any of the forms of double brake in use, sliding of the wheels very seldom occur. In view of all these facts, to what, in your judgment, is the difference between the double brake and the single brake, in respect of this sliding wheels, due?

(Objected to.)

A. In my opinion it is due to two causes, viz: First, that when the single brake has been used there have not been a sufficient number of brake-shoes put in operation to stop the train in the time permitted for the purpose, and, second, that when the single brake was used, a brakeman could only operate simultaneously upon half the number of brake-shoes that he can when double brakes are used.

Recross:

11. Cross-q. Could not, in your judgment, the same effective work in stopping a train be done with the single brake by increasing the number of brakemen?

A. So far as the mere stopping of the train is concerned, I do not know that there would be any great difference between the effect with the single brake and the double brake, assuming that brakesmen
1800 enough were used with the single brake to put the same number of brake-shoes in operation as were put in operation when the double brakes were used.

E. S. RENWICK.

U. S. circuit court, northern district of Illinois.

Thomas Sayles
vs.
The Chicago & Northwestern Railroad Company.

Testimony upon final accounting before the master, taken in the city of New York in pursuance of agreement between the counsel for the respective parties above named, this fourth day of January, A. D. 1872, as follows:

William H. Marlue, a witness duly called and sworn on the part of Thomas Sayles, the above-named complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. My name is William H. Marlue; I am 29 years of age; reside in Jersey City; and am engaged in railroading.

2. Q. Have you ever been engaged as brakeman on railroad trains; if so, how long and what kind of trains?

1801 A. I have been, on local freight, through freight, and passenger-trains; I have been a brakeman about nine years.

3. Q. About how much of this time have you been brakeman on passenger-trains?

A. About half the time, and the rest on freight-trains and shifting in the yard.

4. Q. Please mention some of the roads on which you have been engaged as brakeman during the said nine years.

A. The New Orleans & Jackson; the Mobile & Ohio; Vicksburgh & Meridian; Opelousas; Camden & Amboy; New Jersey.

5. Q. When you were engaged as brakeman on the passenger-trains on these various roads what kind of brakes, whether single-acting or double-acting, did the passenger-cars have?

A. Double-acting.

6. Q. While acting as brakeman on these passenger-trains on these roads, about how much strength did you use at the brake-wheel when stopping the trains at stations on ordinary occasions and at their average speed?

A. I used all the exertion I conveniently could.

7. Q. What, if any, difference was there in respect of the strength used at the brake-wheels between these passenger-trains and the freight-trains you braked on?

A. There was no difference; I set both as tight as I could conveniently.

8. Q. What kind of brakes were used on these freight-trains on which you acted as brakeman?

A. Single-acting brakes, acting only on one truck. At the present time, they have double-acting brakes on the freight-cars of the New Jersey Railroad.

9. Q. State, if you recollect, what kind of double-acting brakes were used on the passenger-cars of the Southern railroads which you mentioned.

1802 A. Some of them had double brakes with a cross lever under the centre of the body of the car, and others had double-acting brakes with two upright levers in each truck.

WILLIAM H. MARLUE.

Sworn to before me this 4th day of January, 1872.

[L. S.] T. B. BEECHER,
Notary Public, N. Y. County.

Frank Singer, a witness duly called and sworn on the part of Thomas Sayles, the above-named complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. My name is Frank Singer; I am 24 years of age; reside in Jersey City, and am a baggage-master on passenger-train running from Jersey City to Perth Amboy.

2. Q. Have you ever been engaged as brakeman on railroad-trains; if so, how long and what kind of trains?

A. I have been. I was brakeman for four years on passenger-trains. I was never brakeman on freight-trains.

3. Q. What kind of brakes—whether single-acting or double-acting—were used on the cars on these passenger-trains on which you were brakeman?

A. Double-acting.

4. Q. While acting as brakeman on these passenger-trains, about
1803 how much strength did you use at the brake-wheel when stopping the trains at stations on ordinary occasions and at their average speed?

A. As much as I could.

FRANK SINGER.

Sworn to before me this 4th day of January, 1872.

[L. S.] T. B. BEECHER,
Notary Public, N. Y. County.

Edward M. Robinson, a witness duly called and sworn on the part of Thomas Sayles, the above-named complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. My name is Edward M. Robinson. I am 27 years of age; reside in Newark, N. J., and am a baggage master on a passenger train running from Jersey City to Rahway.

2. Q. Have you ever been engaged as brakeman on railroad trains; if so, how long and what kind of trains?

A. I have. I was brakeman fourteen months on a train of mixed freight and passenger cars.

3. Q. While you acted as brakeman, about how much strength were you in the habit of exerting on the brake-wheel—on ordinary occasions and while the train was at its average speed—in stopping at stations?

A. I generally put on all the strength I could.

EDWARD M. ROBINSON.

Sworn to before me this 4th day of January, 1872.

[L. S.] T. C. BEECHER,
Notary Public, N. Y. County.

1804 NEW YORK, *January* 12, 1872.

JOHN A. SHARP, a witness duly called and sworn on the part of Thomas Sayles, the above-named complainant, testified as follows:

1. Q. What is your name, age, residence, and occupation?

A. My name is John A. Sharp. I am 56 years of age; residence in Newark, N. J., and am a baggage-master on the Morris and Essex Railroad.

2. Q. Have you ever been engaged as brakeman on railroad trains; if so, how long and what kind of trains?

A. I have. I have been brakeman on passenger trains for five to seven years, and have been baggage-master for seventeen years. I have to apply the brake in my baggage-car every day. I have been on the Morris and Essex Railroad all this time.

3. Q. When you first commenced as brakeman, what kind of brakes were used on the passenger trains on the Morris and Essex road?

A. Single brakes—acting only on one truck.

4. Q. How long was the single brake used on passenger trains while you were brakeman on said road?

A. For a number of years; then the double brake was put on the cars—the Hodge brake, I believe it is called. During the last two years the Hodge brake has been taken off the cars, and the double-acting centre lever brake has been put on all our cars.

5. Q. About how much strength did you apply to the windlass, while using the single brake, when the train was at its average speed, in stopping at stations?

A. About all the strength I could conveniently.

6. Q. And how much of your strength did you apply at the 1805 windlass, while using the double brake, in stopping at stations, when the train was at its average speed?

A. I don't know as there was any difference. I used about all the strength I could in both cases.

7. Q. Did you continue to use about all the strength you could at the windlass until the train came to a full stop?

A. When using the single brake I used to set the brake up as tight as I could, and hold it there till the train stopped; but with the double brake I had better control of the train, and when I could see the train slack I used sometimes to ease up on the brake a little before the train stopped. When the single brake was used the wheels would slide, and the brake didn't hold so well. But with the double brake the wheels were not so liable to slide; after the double brake was put on we had more control over the train.

JOHN A. SHARP.

Sworn to before me this 12th day of January, 1872.

[L. S.] T. B. BEECHER,
Notary Public, N. Y. County.

1806 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILROAD Company.
} In equity.

Testimony of Oliver H. Lee, Charles H. Frisbie, John Ebbert, and James M. Cotting, taken in the matter of the final accounting before H. W. Bishop, esq., master in chancery of said court, before E. B. Sherman, notary public in and for the city of Chicago, in the district aforesaid, by agreement of the attorneys of said parties, complainant and defendant, at the office of West & Bond in said city, at the several times in the jurats of said respective depositions specified.

The said witnesses, being severally duly sworn, testified and deposed as follows on the part of said complainant:

OLIVER H. LEE, a witness of lawful age, being produced, cautioned, and solemnly sworn to testify the truth, the whole truth, and nothing but the truth, in the matter in controversy aforesaid, in answer to interrogatories to him propounded, deposed as follows, to wit:

Q. 1. What is your name, age, residence, and occupation?

A. Oliver H. Lee; 57 years; Chicago; merchant.

1807 Q. 2. Were you at any time superintendent of the Hudson River Railroad? If yea, state when.

A. I was; during the years 1850, 1851, and part of 1852.

Q. 3. While such superintendent, were any experiments made by you, or under your direction, for the purpose of testing the comparative value of single-acting and double-acting brakes on railroad cars? State fully all facts connected with such experiments, if any such were made.

A. Such experiments were made under my direction; I referred the matter of brakes to W. T. Ragland, superintendent of car machinery on the said Hudson River Railroad, directed him to try the different kinds of brakes on the passenger cars on said railroad, test them thoroughly, and report to the company. The particular object of inquiry was to find the brake which would stop the cars soonest without injuring the wheels—I mean with the least wear on the wheel by sliding on the track while the train is in motion, thereby causing a flattened surface on the periphery of the wheel.

Q. 4. State when you directed these experiments to be made.

A. In the spring of 1852; I think I left the road in May, 1852; I left before the experiments were completed.

OLIVER H. LEE.

Subscribed and sworn to before me this 20th day of Dec., 1871.

E. B. SHERMAN,
Notary Public.

(Cross-examination waived.)

1808 CHARLES H. FRISBIE, a witness of lawful age, being produced, cautioned, and solemnly sworn to testify to the truth, the whole truth, and nothing but the truth, in the matter of controversy aforesaid, in answer to interrogatories to him propounded, testified as follows, to wit:

Q. 1. What is your name, age, residence, and occupation?

A. Charles H. Frisbie; 48 years; I reside in Rockford, Illinois; and am an engineer—a locomotive engineer.

Q. 2. How long have you been such engineer, and on what roads have you run?

A. Since 1850; Michigan Central, Chicago, Burlington and Quincy, Chicago, Pittsburgh and Fort Wayne, Chicago and Northwestern.

Q. 3. On what trains did you run on the Michigan Central Railroad, and what kind of brakes were used on such trains?

A. I run on passenger and also on freight trains. When I first commenced running on the Michigan Central, they used the single brake on the cars in the passenger trains; on the freight cars, generally, they then used no brakes, but on a few cars they had single brakes.

Q. 4. While such single brake was in use on passenger cars of the Michigan Central Railroad, did you, as engineer, have to do anything to assist in stopping trains at stations; and, if so, what?

A. I frequently had to reverse my engine, in order to stop the train at the proper place.

Q. 5. How frequently did you have to do this?

A. Such was the general practice among engineers at that time. We had instructions from the superintendent to stop the trains by reversing the engine, if they did not stop them with the brakes. Ordinarily I had to reverse the engine as often as every alternate station and sometimes oftener.

1809 Q. 6. Were the brakes upon the passenger cars of said railroad changed before you left it; if so, what change was made?

A. They were changed from single to double brakes.

Q. 7. What effect, if any, did this change have upon the facility with which trains could be stopped?

A. After we had the double brake we never had to reverse the engine except in special cases. For all ordinary cases, the brakes were sufficient to stop the trains.

Q. 8. On what trains did you run as engineer on the other roads you have mentioned?

A. Both passenger and freight.

Q. 9. What brakes have been used, if any, on the passenger trains of such roads, while you run as engineer—employed upon them?

A. None other than double brakes to my knowledge.

Q. 10. What means have been employed for stopping such passenger trains at stations?

A. The brakes alone have been sufficient in all ordinary cases; I have not found it necessary to reverse the engine to aid in stopping, except in special case—in cases of danger.

Q. 11. State what effect, if any, it has upon a locomotive engine to reverse it under headway as often as you have said it was necessary to do when single brakes were in use.

A. It had a tendency to make the flues leak; it made a very heavy strain upon the engine every time it was reversed, especially when under great speed; it strained every part of it. I recollect one occasion in particular that I reversed my engine under headway, and it disabled one side of her—one engine entirely; it broke her eccentrics and link and eccentric rods, breaking the engine throughout.

Q. 12. On what railroad were you running when you first saw double-acting car-brakes in use?

A. On the Michigan Central Railroad.

1810 Q. 13. What kind or construction of double-acting car-brake was first put in use on the Michigan Central Railroad?

A. The one with the lever under the centre of the car-body.

Q. 14. Upon what railroad are you running as engineer at the present time?

A. The Chicago and Northwestern.

Q. 15. How long have you run as engineer upon the Chicago and Northwestern Railroad?

A. Six or seven years.

Q. 16. During that time, have you run part of the time upon passenger trains upon that road?

A. Yes, sir.

Q. 17. State whether you found any difference, and, if any, what difference, between the facility with which you could stop the passenger trains at stations upon the Michigan Central Railroad, without reversing the engine, at the time when they used the car-brake having a lever under the centre of the car body, and the facility with which you could do the same thing on the passenger trains of the Chicago and Northwestern Railroad, with the form of double brake used on those trains.

A. I never could see any difference.

Q. 18. What kind of a train are you at present running on the Chicago and Northwestern Railway?

A. A way-freight train between Chicago and Rockford. That is ninety-three miles from Chicago.

Q. 19. About what is the average number of freight cars run in that train?

A. About fifteen cars, taking the whole year through, but all the way from fifteen to forty cars during the summer season.

Q. 20. Are the freight cars in that train of the ordinary weight and size of the other freight cars of the Chicago and Northwestern Railway, and of the other railroads in this section of the country?

1811 A. Yes; we have cars in that train from all the roads about here, except that I don't remember ever seeing any cars from the Pennsylvania road in it. The cars are of the average size and weight, taken all together.

Q. 21. What kind of brakes are used on the freight-cars of that train?

A. The single brake.

Q. 22. Is there any other car in that train except the freight-cars? If so, what kind of a car is it, and in what part of the train is it placed?

A. There is a car that we call a way-car; on some roads this kind of car is called a caboose-car. It always is run at the rear end of the train.

Q. 23. What kind of a brake is there on the "way" car in your train?

A. A double brake; it brakes on both trucks at the same time.

Q. 24. Of the cars of this train, which are relied upon by the men on the train to stop the train whenever it is necessary to stop it?

A. We put more reliance upon the way-car than upon all the rest of the cars in the train, always. There is more reliance to be put upon it.

Q. 25. State whether you ever hear any complaint from the brakemen on that train as to the brakes of the freight-cars; if so, what do they say about them?

A. They frequently tell me that after putting on half a dozen brakes they find that they can't hold the train with them. I have often asked them why they didn't hold the train, and they have said that they put the single brakes on and they didn't hold at all. They have often told me that there wer'n't any brakes on the train that were good for anything to hold the train except the brakes on the way-car.

Q. 26. Independent of what the brakemen say, what is your own experience of the effect of the single brakes on the freight-cars in holding your train?

1812 A. I could say with perfect safety, that according to my experience they are not worth much of anything to hold the train, generally speaking.

Q. 27. State, if it is within your knowledge, any reason why these brakes on the freight-cars don't hold the train any better.

A. One reason is, that I have frequently seen, when the brakes were on, that they held the four wheels of a car—that is, one truck—so that they would slide on the track; and when they slide on the track they don't hold so well as when they roll slowly.

Q. 28. State whether you are ever able to draw your train with your engine when a considerable number of the brakes of the freight-cars are on, the brake on the way-car not being on.

A. Yes, I have often done it. When the single brakes are on they don't seem to hold much. Anybody that hasn't had practical experience in these things wouldn't believe that these single brakes hold so poor as they do.

Q. 29. State whether you can draw your train when the brake of the way-car is put on.

A. Not generally, unless I am on a down grade or have got my train well under headway. Sometimes I can start my train with the way-car brake on, but I can't get a great ways without feeling it; and often when the men on the train want to stop it at some irregular place and can't get any signal to me on the engine, they put the way-car brake on, and I feel that right away, and know they want to stop, and I stop my engine. I have frequently known, when the train was under headway and then the way-car brake was put on, that it would tear the train in two, and break the pins and couplings; part of the train would be with the way-car and part with the engine.

Q. 30. About what is the average weight of freight-cars in your train, when they have an average load, and what is the speed at which they run?

A. On an average, from eighteen to twenty tons, including the car itself. The speed I run at is about fifteen miles an hour.

1813 Q. 31. How long have you run on that train?

A. Between four and five years.

Q. 32. What experience have you had in running trains on other railroads?

A. I ran freight trains most of the time I was on the Chicago, Burlington and Quincy Railroad, and most of the time I was on the Chicago, Pittsburgh and Fort Wayne road. I was running freight trains on these two roads, both together, about five or six years in all.

Q. 33. What kind of brakes were used on the freight cars on these last two mentioned roads when you ran them?

A. I never knew of any except the single brakes.

Q. 34. State whether on the freight trains on these last two mentioned roads there were any way or caboose cars; if so, how many to a train?

A. Yes, sir; each freight train on each road had one caboose car on the rear end.

Q. 35. What kind of brakes were on these caboose-cars on these roads?

A. The double brake.

Q. 36. In running these freight trains on these roads what brakes were relied upon to stop the trains?

A. The double brakes on the caboose-cars.

Q. 37. State, if you know, how generally it is the practice in this section of the country to run caboose or way cars on the rear end of freight trains.

A. They run them on all the roads running out of Chicago, and on all the roads I ever knew anything about everywhere.

C. H. FRISBIE.

Subscribed and sworn to before me, this 20th day of December, 1871.

(No cross examination.)

1814 JOHN EBBERT, a witness of lawful age, being produced, cautioned, and solemnly sworn to testify the truth, the whole truth, and nothing but the truth, in the matter in controversy aforesaid, in answer to interrogatories to him propounded, testified as follows, to wit:

Q. 1. What is your name, age, residence, and occupation?

A. John Ebbert; 55 years; Chicago; am an engineer. Have been the greater part of my life a locomotive engineer. Was several years master-mechanic of the Chicago & Galena road.

Q. How long have you been a locomotive engineer, and on what railroads have you been employed?

A. About 20 years—from about 1835 to about 1855. I was first on the Allegheny Portage road; afterwards on the Michigan Central Railroad; then the Galena & Chicago Railroad; then on the Ohio and Mississippi Railroad; also on the Western Railroad of Massachusetts, between Albany and Worcester. This last was after I left the Michigan Central. I mean immediately after.

Q. 3. What trains did you run on as engineer on these several roads?

A. Both freight and passenger, on each.

Q. 4. What brakes were in use on the passenger cars of these roads in the trains run by you as engineer?

A. The Allegheny & Portage road used four-wheel cars, and the brake used was a single-acting brake; on all the other roads single-acting brakes were used, operated from only one end of the car.

I went on the Galena road in the latter part of 1848; the single brake was then used on that railroad on its passenger cars, and continued so to be used until 1852 or 1853, when they commenced using double brakes, operated from either end of the car.

1815 Q. 5. While single-acting brakes were in use on the Galena road aforesaid upon the cars in its passenger trains, what, if anything, did you, as engineer, have to do in stopping such trains at stations?

A. I usually handled the trains at stations by reversing the engine to assist the brakes. I mean I had to reverse the engine to help stop the trains.

Q. 6. How many single brakes were in use on each car?

A. Some had one on each end, and some had only one.

Q. 7. After the double-acting brakes, as you say, were used on the passenger-cars on said Galena road, what, if anything, did you have to do, as engineer, to assist in stopping trains at stations?

A. It was seldom after the double brakes were used that we reversed the engine; the cars were handled by the brakes altogether. Sometimes at the water-tanks we reversed the engine after the train was, so to speak, stopped, because we had to get within six inches to get water.

Q. 8. While engineer upon the other roads which you have mentioned, what, if anything, was it customary for you, as engineer, to do in stopping, at stations, passenger-trains upon the cars of which single-acting brakes were in use?

A. We handled the train generally by reversing the engine to assist the brakes. Engineers generally did this on all roads I have been connected with.

JOHN EBBERT.

Subscribed and sworn to before me this 20th day of December, 1871.

E. B. SHERMAN,
Notary Public.

(No cross-examination.)

1816 JAMES M. COTTING, a witness of lawful age, being produced, cautioned, and solemnly sworn to testify the truth, the whole truth, and nothing but the truth, in relation to the said matter in controversy, testified as follows, to wit:

Int. 1. What is your name, age, residence, and occupation?

Ans. James M. Cotting; 45 years; Bloomington, Ill.; have been the greater part of my life railroading—part of the time as engineer, and part as conductor.

Int. 2. On what railroads have you been employed, and in what capacities?

Ans. On the Hudson River first two years—working in the car-shop, and one year running a stationary engine; afterwards on the Alton & S't Louis road as locomotive engineer and conductor of passenger-trains.

Int. 3. About what years were you employed on the Hudson River road, and under whom as master of car repairs?

Ans. 1851 and '52; Major W. T. Ragland was at that time master of car repairs.

Int. 4. At the time you first went on to the Hudson River road, what kind of brakes were in use in the cars in the passenger-trains of that road?

Ans. The single brake.

Int. 5. Was there at any time while you were employed there any change made in the brakes on the cars in the passenger-trains on said road; if so, what change was made?

Ans. There was; to the double-acting brake.

Int. 6. What experiments, if any, were made about the time that double brakes were put in the place of the single brakes, for the purpose of testing the comparative value of the two kinds of brakes? State whatever you know about this matter.

1817 Ans. About that time some experiments were made by Major Ragland; but what the exact nature of the experiments were, or the result, I don't know.

Int. 7. While you were in the employ of the Hudson River Railroad Co., did you have opportunities to observe the effect of car-brakes upon the car-wheels—both when the single brakes were used and when the double brakes were used? If yea, please state what your opportunities were.

Ans. I did; it was part of my duty to take out worn wheels and put in new ones.

Int. 8. State the effect of each kind of brake on the wheels?

Ans. When the single brakes were used, the wheels would slide on the track and wear flat places on them; but after the double brake was used, they broke on the wheels more evenly—the wheels did not slide so much, and therefore lasted longer than when the single brakes were used.

Int. 9. How much longer, and what would the saving be?

Ans. With the double brake, the saving would be from two to three sets of wheels a year.

JAMES M. COTTING.

Subscribed and sworn to before me this 5th day of January, A. D. 1872.

E. B. SHERMAN,
Notary Public.

(No cross-examination.)

CHICAGO, *Jan. 24th*, 1872.

1818 HORATIO ANDERSON, being duly called and sworn on behalf of the complainant, testified as follows:

Q. 1. What is your name, age, residence, and occupation?

A. Horatio Anderson; age, forty-seven; residence, Chicago; I am not at present in any business; I have been, until within two years, master mechanic of the Chicago and Northwestern Railroad.

Q. 2. Please state what was your occupation between the month of July, 1859, and the 2d of June, 1864?

A. I was master mechanic of the Chicago and Northwestern Railroad.

Q. 3. Please state whether, during this time, your position as master mechanic required you to know the number of locomotive engines used on trains for the conveyance of passengers on said Chicago and Northwestern Railroad.

A. Yes; it did.

Q. 4. How many such engines were there used during said time?

A. There were ten regular passenger engines at that time, and two more running on mixed passenger and freight trains between Harvard and Rockford—one train each way every day.

Q. 5. How many of these twelve engines were in daily use for the purpose mentioned?

A. All of them. When one of them was laid up a freight-engine had to be taken to be used in its place.

Q. 6. State whether the duties of a master mechanic enabled you to become familiar with what would be the effect upon a locomotive engine of reversing it frequently under headway—for instance,
1819 say half of the time in stopping passenger-trains at stations?

A. They did.

Q. 7. Please state what such effect would be.

A. Damaging the engine in every part more or less. It racks the engine and strains it all through. It would soon tear the engine all to pieces.

Q. 8. Will you please state how much more, in your judgment, if any more, it would cost for the yearly repairs of a locomotive engine which was reversed under headway as often, say, as at two-thirds of the stations on the Chicago and Northwestern Railroad between July, 1859, and June, 1864, as compared with such cost when a locomotive was reversed no oftener than was done on said road after the double-acting brake was in use there?

A. I don't think a thousand dollars a year would cover it. Perhaps fifteen hundred dollars an engine per year would cover it.

Q. 9. Please state whether it is necessary to reverse locomotive engines under headway in stopping passenger trains at stations when the double brake is used on such trains.

A. No; it is not.

Q. 10. Please state to what element in the double brake this capacity to dispense with the reversing of engines to stop trains at stations is due.

A. It is due to the fact that in the double brake the brakes at both ends of the car are connected together and are placed under the control of a single mind, and are operated by that mind at the same instant.

Q. 11. State whether there is any advantage in this respect, and, if any, what advantage in the Hodge brake or the Stevens brake over the Tanner brake.

A. I do not think there is any.

1820 Q. 12. Please state whether you are familiar with the construction and operation of the Tanner, Hodge, and Stevens brakes.

A. I am. I have seen them all in operation.

Q. 13. With which brake, the Tanner or the Stevens, will the car-wheels last the longest in your judgment?

A. I don't know that there would be any difference.

HORATIO ANDERSON.

Subscribed and sworn to before me this 24th day of January, A. D. 1872.

[L. S.] J. HOWLAND THOMPSON,
Notary Public.

(No cross-examination.)

1820½ THOMAS SAYLES
vs.
THE CHICAGO AND NORTHWESTERN RAILWAY Company. } In chancery.

Exhibit No. 9 in supreme court record.

W'M H. BRADLEY, *Clerk.*

1821 Circuit court of the United States, northern district of Illinois.

THOMAS SAYLES
versus
THE CHICAGO AND NORTHWESTERN RAILWAY Company. } In equity.

Defendants' proofs upon final accounting before the master.

1822 [NOTE.—The deposition of M'r Stephen M. Whipple before the master has, by agreement between the respective counsel, been omitted from the herein printed testimony because it is not material to the subject of the accounting in the case. The asterisks which occur in some of the ensuing depositions denote that a few of the questions and answers in such depositions which are not material to the subject of the accounting have, by similar agreement, been also omitted.]

U. S. circuit court, northern district of Illinois.

THOMAS SAYLES
vs.
CHICAGO AND NORTHWESTERN RAILROAD COMPANY. } In chancery.

In pursuance of an order entered in said cause on the 13th day of February, 1865, by which a reference was made to the undersigned, a master in chancery of said court, to take testimony in said cause, I, H. W. Bishop, j'r, master in chancery aforesaid, hereby report that on Wednesday, the 16th day of January, A. D. 1867, and on other days
1823 subsequent thereto, I was attended by Thomas Sayles, the complainant herein, and by H. W. Blodgett, esq., solicitor for the defendant, who produced before me Stephen M. Whipple, N. W. Huntley, Stephen E. Knott, S. J. Hayes, H. Gray, Benjamin Garvin, and Thomas Hull, who, having been by me first duly cautioned and sworn, testified as in their examination hereunto annexed will fully appear; and I further certify that by stipulation between the parties before me it was agreed that the testimony of George M. Dunlap and William A. Ingalls, witnesses also on the part of defendant, should be taken before John T. Reilly and returned by me with the testimony of the other witnesses heretofore mentioned, and that the testimony so taken as last aforesaid should be used as if the same had been actually taken before me under said order.

And I further report that I now return said testimony with the other testimony taken before me as aforesaid.

1824 *Testimony on behalf of the defendants.*

• • • • • •

Testimony of NATHAN W. HUNTLEY, called by defendants:

Q. 1. What is your name, age, and occupation, and where do you now reside?

A. Nathan W. Huntley; I am thirty-seven years of age; I reside in Chicago; I am a mechanic by occupation.

Q. 2. Are you acquainted with the parties to this suit? If yea, how long have you known them respectively?

A. I am; I met M'r Sayles before the present time, five or six years ago, and met him once or twice since that time. I have known the defendants ever since they assumed the name of the Chicago and Northwestern Company.

Q. 3. State what have been your facilities and opportunities for becoming familiar with the subject of mechanics, particularly relating to railroad machinery?

A. It has been my study and practice for fifteen years; I have manufactured and put on myself; I have manufactured almost everything connected with railroad machinery, and under my own supervision have had it manufactured myself.

Q. 4. Have you been connected with railroads in any capacity, and, if so, in what capacity, and how long?

A. I have been connected with railroads for fifteen years;
1825 first as a journeyman, and then as foreman in general car repairs on the road. Then as master carpenter, having charge of all repairs of cars and buildings on the road; then as master mechanic,

having charge of the motive power, as well as car building. I was connected with the Great Western road, of Canada, first; was there a short time; was then connected with what is now the Northwestern road, in Chicago. Then with the Chicago and Milwaukee road. I am not connected with any railroad now; I left the first of last June the service of the Milwaukee road, at the time the Northwestern took control.

Q. 5. Are you familiar with railroad brakes that are now used on railroads, and particularly are you acquainted with the so-called Tanner and Stevens brakes; if yea, how long have you known them?

A. Yes, I am; I know the Tanner and Stevens brakes; I have known them fifteen years.

* * * * * * *

Q. 9. Do you know what brakes are used on the road of the defendant; if yea, what are they?

A. I know the general brake used—the old single brake, and the so-called Stevens double-acting brake, known as the Stevens brake.

Q. 10. In the use of the Stevens brake, what proportion of brakemen does it take to brake all the wheels of a car, in comparison with the old single-acting brake to accomplish the same purpose?

A. One-half the number.

Q. 11. How many brakemen does it take to a car to brake all the wheels by the use of the single-acting brake at the same time?

A. Two; provided the brakes are on both trucks.

Cross-examination by complainant:

Cross-q. 1. How many brakemen would it require to apply the brakes on all the wheels of two cars in a train with the so-called Tanner 1826 brake, as are now practised by railroad companies?

A. It would require two; it is the usual custom for one brakeman to brake two cars, braking from the rear end of one car and the forward end of the other.

Cross-q 2. How many brakemen would be required to apply the brakes to all the wheels of two cars in a train with the single brake—as usually practised I mean?

A. It would require three.

* * * * * * *

Cross-q. 7. Does the Tanner patent apply the brakes to all the wheels of a car simultaneously from either end of the car, by means of the windlasses and connecting rods and levers?

A. It does.

Cross-q. 8. Does the Stevens patent car brake apply the brakes to all the wheels of a car simultaneously from either end of the car by means of the windlasses and connecting rods and levers?

A. With perfect mechanism and construction it would.

* * * * * * *

Cross-q. 10. In your direct examination you have stated certain differences to exist between the construction of the Stevens brake and the Tanner brake; are we to understand that you consider the Stevens brake an improvement on the Tanner brake?

(Objected to.)

A. Well, for the purposes that the two brakes are designed for, it is an improvement on the Tanner brake.

Redirect:

1827 Q. In a train of two cars using the Stevens brake, how many brakemen would it require to simultaneously apply the brakes to all the wheels of the train?

A. It would take two.

Recross:

Cross-q. 11. In a train of two cars using the Stevens brake, how many brakemen would it require to apply the brakes to all the wheels of the train as now generally practiced by railroad companies?

A. One; braking from rear end of one car and the forward end of the other car.

Cross-q. 12. Is it necessary, in your opinion, to apply the brakes to all the wheels in a passenger train of cars, as a general thing, for the safety of the train?

A. In case of danger, it is necessary to apply all the retarding force possible to the speed of the train.

N. W. HUNTLEY.

Subscribed and sworn to before me, and read over before signing, February 23d, 1867.

H. W. BISHOP, J'R,
Master, &c.

Testimony of THOMAS HULL, called by defendants:

Q. 1. What is your name, age, residence, and occupation?

A. My name is Thomas Hull; forty-six years; residence, Chicago; and I am master of the car department of the Chicago and Northwestern Railroad Company, Wisconsin Division.

Q. 2. Are you acquainted with the parties to this suit; if yea, how long have you known them?

A. I am not acquainted with the complainant.

1828 Q. 3. How long have you been in the employ of the Chicago and Northwestern Railway Company?

A. I have been directly connected with the car-department nine or twelve years—nine years certainly.

Q. 4. Do you know what brake was used on the Chicago and Northwestern Railway—the passenger-cars—from June, 1859, to June, 1864? If yea, state what brake was used.

A. I do know; it was the Stevens brake that was used.

Q. 5. Was the brake commonly called the Tanner brake used on this road during this time?

A. Not to my knowledge.

Q. 6. On a train of passenger-cars, to secure the highest degree of safety, how many brakemen does it require?

A. I should put one to every car.

Cross-examination:

Cross-q. 1. Do you consider it necessary to apply the brakes to all the wheels of a passenger-train, when stopping at stations, or in case of obstructions on the track, or in case of accidents to the train, for the safety of the passengers and train?

A. I do.

Cross-q. 2. According to the general practice of railroad companies, how many brakemen would it require to apply all the brakes to six cars in a train while using this Stevens or Tanner brake?

A. Three brakemen.

Cross-q. 3. How many brakemen would it require to apply all the brakes to such a train with the old single brake?

A. Seven brakemen.

THO'S HULL.

Subscribed and sworn to before me March 5, 1867.

H. W. BISHOP, J'R,
Master, &c.

1829 Testimony of SAMUEL J. HAYES, called by defendants.

Q. 1. What is your name, age, and occupation, and where do you now reside?

A. My name is Samuel J. Hayes; I am forty-nine years; I reside in this city; I am a mechanical engineer; I have superintending of the machinery on the Illinois Central Railway—all the machinery on that road.

Q. 2. Are you acquainted with the parties to this suit; if yea, how long have you known them?

A. I am; I have known the officers of the Northwestern road six or eight years; have not been acquainted with M'r Sayles a great while; I have met him a few times.

Q. 3. Are you familiar with the subject of mechanics? If yea, state what have been your facilities for acquiring a knowledge of the subject—particularly relating to railroad machinery.

A. I am—to first question. In 1835 I was an apprentice to Ross Winans, in the city of Baltimore; I served my regular apprenticeship—steam-engine building, locomotive building—under M'r Ross Winans. In 1840 I was transferred from Winans' shop to the company's shop—Baltimore and Ohio Railroad Company's shop—and placed as general foreman over their engines and cars—which situation I filled till 1847. At that time I was placed as general master mechanic over all their machinery. I remained in that position until in 1851, when I took the superintendency of the rolling stock of the whole road. I remained in that till in 1856, when I left and came to Chicago, to take a similar situation with the Illinois Central Railroad, where I remain at present. During that time—from 1847 till the present time—the drawings, plans, designs of the engines and cars have been made under my charge and direction for both of said roads.

1830 Q. 4. Are you acquainted with the so-called Tanner patent car-brake, and the Stevens patent car-brake?

A. I am.

* * * * * * *

Q. 11. Take a train with a given number of eight-wheel coaches as they were made and used when the old single brake was in use, and a train with the same number of eight-wheel coaches using the double-acting brake, was it the custom to use more brakesmen with a single-acting brake than is commonly used with the double-acting brake?

A. There was not any more brakesmen used with the old-fashioned brake than with the double brake on roads I have been connected with, nor have I noticed that there was in my observation in passing over other roads. It has always been the custom to have two brakemen on an ordinary passenger-train, and it is still the custom.

Cross-examination:

Cross-q. 1. Suppose a passenger-train with four cars with the double-acting brakes on said cars, would, in your opinion, two brakemen be more than would be necessary for the safety of that train?

A. No, sir.

Cross-q. 2. How many of the wheels of that train of four cars would the two brakemen apply the brake to with the said double brake?

A. That would depend on the position in which you placed the brakemen.

Cross-q. 3. As brakemen are usually placed on such a train of cars?

A. They would apply the power to the whole 32 wheels—all the wheels on the train.

Cross-q. 4. How many brakemen would it require to apply the brakes to all the wheels of such a train with the old single brake?

1831 A. The same nunber of brakemen could do it by running through the cars—by applying them on one platform and running through to the next, as they used to do.

Cross-q. 5. How many brakemen would it require to apply the brakes to all the wheels of such a train as quick with the single brake as the two brakemen could with the double brake?

A. It would take five.

Cross-q. 6. Do you consider that it would be safe in stopping a train of passenger-cars in case of obstructions being seen on the track by the engineer, and he blowing his whistle for the brakeman to apply the brakes, to depend on brakemen applying the brake at one end of the cars and then running through the car to apply it to the other end with the single brake?

A. If the obstruction was permanent, I should consider it unsafe.

Cross-q. 7. Is it not often the case that from obstructions being seen on the track, or other cause, that it is necessary for the safety of the train and passengers therein that the train should be stopped in going the shortest possible distance?

A. It is.

Cross-q. 8. In that case do you consider it would be safe to depend on the brakemen running through the cars on the train, first applying the brake on one end of the car and then the other—as he would have to do with the single brake?

A. Being schooled as we are now to the use of the double brake, we would not consider it so, but we did consider it so at one time in the history of railroading; that was the custom.

Cross-q. 9. State how long ago.

A. Well, 18 or 20 years ago.

Cross-q. 10. There were no double brakes in use 18 or 20 years ago, were there?

A. Not in general use, I believe; might have been some few in use.

1832 Cross-q. 11. State whether you knew of any at that time—double-acting brakes?

A. I think I have seen some few of them in use 20 years ago.

Cross-q. 12. On what road did you see them in use 20 years ago?

A. I think I seen them in use upon some tenders on the Baltimore and Ohio road; and, also, on some tenders and cars, I think, on the Baltimore and Susquehanna road.

Cross-q. 13. Are there double-acting brakes in general use on the different railroads in this country?

A. There are upon passenger-trains; not in general use on freight-trains.

Cross-q. 14. Do you know of any railroad—any prominent railroad—in this country where the single-acting brake is in general use on their passenger-trains ?

A. I do not.

Cross-q. 15. According to the general practice of applying the double-acting brake to passenger-trains, how would the number of brakemen in applying the brake to such trains with the single-acting brake compare ?

A. It would take double the number with an odd number of cars to apply the brakes in the same time.

Cross-q. 16. An even number of cars in a train ?

A. With an even number, it would take one more than double the number for each train.

* * * * * *

Cross-examination resumed by M'r Sayles:

Cross-q. 19. Would you consider it safe now (considering the improvements that have been made in railroad machinery, and especially in
car brakes, during the last 20 years) to run passenger-trains, as
1833 generally they are now run, with the same number of brakemen
that were engaged on passenger-trains 20 years ago with the
single brake ?

A. I should not, with our present knowledge of railroad machinery.

Cross-q. 20. Were passenger-trains 20 years ago run at the same rate of speed as they are now ?

A. I think not; in this country the speed is greater now than it was twenty years ago.

Cross-q. 21. Is it, or is it not, necessary when a train is run at a high rate of speed, to have more brakemen on a train, as a general thing, than when run at a low rate of speed ?

A. Yes, it is; considering the same number of cars on the train.

S. J. HAYES.

Subscribed March 14, 1867, before me.

H. W. BISHOP, J'r,
Master, &c.

Testimony of **Benjamin Garvin**, called by defendants.

Q. 1. State you' name, age, occupation, and residence.

A. My name is Benjamin Garvin; my age, 43; my residence, Fond du Lac, Wisconsin; and my occupation is foreman of the shop for the repairs of engines at Oshkosh.

Q. 2. How long have you been connected with railroads, what roads have you been connected with, and in what capacity ?

A. I have been connected with railroads for twenty-four years; the Concord and Nashua, Northern New Hampshire, Vermont Central, and the Chicago and Northwestern Railroads, as locomotive-engineer and foreman of shop.

1834 Q. 3. Have the roads that you have been connected with used the single and double-acting brake ?

A. They have.

Q. 4. Take a train with a given number of eight-wheeled coaches in, as they were made and used when the old single brake was in use, and a train with the same number of eight-wheeled coaches, using the double-acting brake, was it the custom to use more brakemen with the single-acting brake than is used with the double-acting brake?

A. It was not.

Q. 5. Were accidents upon passenger-trains caused by the brakes giving way, or getting out of repair, any more frequent in the use of the old single brake than they are now in the use of the double-acting brake?

A. I don't think they were; brakes are generally better taken care of when they are single than when they are double; if a double brake is not kept well adjusted, it don't amount to much—don't amount to any more than a single brake.

Cross-examination:

Cross q. 1. What double brakes have you referred to in your last answer?

A. Either—any double brake.

Cross-q. 2. Hodges', Stevens', and Tanners'—are you acquainted with all of them?

A. I have seen them all used.

Cross q. 3. Why were the double brakes not as well taken care of as the single brakes?

(Objected to.)

A. They depended too much on the double brake, because they had a double brake.

Cross-q. 4. Is the double brake, then, generally considered much safer and better than the single brake on passenger-trains?

A. I never considered it any safer or any better.

1835 Cross-q. 5. I don't ask you what you consider—I ask you generally.

A. I am not conversant with adjusting brakes, but I know when it works well and is taken care of.

Cross-q. 6. How long since you have known the single brake to be in general use on any railroad, and what railroad?

A. I think it has been about fourteen years since the single brake has been used on passenger-cars.

Cross-q. 7. On what road do you know it to be used fourteen years ago?

A. I think we used them on the Vermont Central and the Northern New Hampshire. I think they were using both single and double at that time.

Cross-q. 8. Did passenger-trains run at the same rate of speed then that they do now?

A. They run faster when they used the T rail.

Cross-q. 9. Is the double-acting brake in general use on the railroad that you are connected with now?

A. They are; on passenger-cars.

Cross-q. 10. How long have you been connected with the Northwestern Railroad?

A. Thirteen years this spring, I think.

Cross-q. 11. During the last six or eight years, do you think that company has employed more brakemen on their passenger-cars than has been necessary for the safety of their trains and passengers?

(Objected to.)

A. I think they could have got along with less, and done it just as safe—that is, in some cases, perhaps—as a general thing they need them all.

BENJAMIN GARVIN.

Subscribed before me this 19th day of March, A. D. 1867.

H. W. BISHOP, J'R,
Master, &c.

1836 **APRIL 3D, 1867.**

Testimony of GEO. L. DUNLAP, called by defendants:

Q. 1. What is your name, age, and occupation?

A. Geo. L. Dunlap; sup't Chicago & Northwestern Railroad; 38 years of age October, 1866.

Q. 2. Are you acquainted with the general practice of managing railroads?

A. I am.

Q. 5. How long have you been engaged or connected with railroads, and what have been your relations? State fully.

A. For 19 years continually. First, on Boston & Maine road, in general superintendent's office; on N. Y. & E., general ticket agent; then on C. & N. W. as superintendent.

Q. 4. Are you acquainted with the brakes that were used on these various roads?

A. I am.

Q. 5. How long has the double-acting brake been in use?

A. More or less since 1850—not generally till then.

Q. 6. What other brakes were used besides the double-acting?

A. The single brake.

Q. 7. As it has been generally the practice, did or did it not require more brakemen to run a train of cars with a given number of coaches using the single than when using the double-acting brake?

A. The general practice was they used more brakemen then than now.

Q. 8. Were or were not the trains as safely run when the single brake was used as when the double-acting brake was used?

A. So far as the general agency of the brakes is concerned, I don't think it makes much difference; so far as accidents are concerned, it is no matter what kind of brakes is used; about so many accidents will occur.

1837 Q. 9. In the usual running of trains, was it the practice to stop them as quickly while using the single brake as it is when using the double-acting brake?

A. I should say it was.

Q. 10. What brake is used on the Chicago & Northwestern?

A. Stevens brake—on passenger trains.

Q. 11. In the use of the single brake, did the car wheels wear a longer time or less time than in the use of the double-acting brake?

A. I can't recollect about that.

Cross-examination:

Cross-q. 1. Is the double-acting brake in general use on the railroads of this country?

A. It is.

Cross-q. 2. Were you superintendent of the Chicago & Northwestern Railroad from June, 1859, to June, 1864?

A. I was.

Cross-q. 3. Did you employ more brakemen on the passenger trains during that period than you considered necessary for the safety of the trains and passengers?

A. I did not.

GEO. L. DUNLAP.

Subscribed before me this 3d day of April, 1867.

H. W. BISHOP, J'R,
Master, &c.

1838 **DEFENDANTS' PROOFS.**

Reported by J. M. W. Yerrington.

The following witnesses were duly sworn and their depositions taken, at Springfield, Mass., July 31, August 2, 3, 5, 1872:

Deposition of William H. Russell.

Direct examination by S. M. Whipple:

Int. 1. What is your name, age, residence, and occupation?

A. My name is William H. Russell; age, 53; residence, Springfield; occupation, road-master and wood agent of the Boston and Albany Railroad.

Int. 2. Please state the mountain range across which the Boston and Albany road runs between Springfield and Albany.

A. What is called the Green Mountain range.

Int. 3. What are the grades on the eastern slope?

A. The heaviest east grade is 85 feet.

Int. 4. What are the grades on the western slope, towards Pittsfield?

A. Seventy-five feet.

Int. 5. What are the grades on the line between Springfield and Boston?

A. Sixty feet is the heaviest.

Int. 6. Please state the number of feet of the different stations, or most of them, above tide-water.

A. Framingham, 162 feet; Worcester, 473 feet; Worcester Junction,
473 feet; Charlton, 898 feet; Brimfield, 604 feet; Palmer, 334
1839 feet; Springfield, 69 feet; Westfield, 149 feet; Chester, 602 feet;
Middlefield, 979 feet; Washington, 1,494 feet; Pittsfield, 1,069
feet; State line, 954 feet; Canaan, 867 feet; Chatham, 460 feet; Chatham
Centre, 305 feet; Greenbush, 25 feet.

Int. 7. Please state the radius of some of the sharpest curves on your entire line.

A. Well, between here and Pittsfield our sharpest is 764 feet; between Pittsfield and Albany, 818 feet; east of Springfield, 1,432 feet.

Int. 8. How many stations are located on curves on your line of road between Springfield and Albany?

A. Twenty-four: Cottage Farm, Brighton, Auburndale, Riverside, Rice Flag station, Grantville, Wellesley, Westborough, Rochdale, Warren, West Warren, Brimfield flag station, Huntington, Chester, Middlefield, Becket, Hinsdale, Richmond, State line, Canaan, East Chatham, Chatham Centre, Kinderhook, Scodack.

Int. 9. Are all these stations you have mentioned on curves?

A. Yes, sir.

Int. 10. How sharp are these curves?

A. There is only one that is over 2,865 feet; that is at East Chatham. That is 1,432 feet. That is the shortest radius.

Int. 11. About what are the others?

A. Probably they would not average more than 4,000 feet. They are on slight curves, most of them.

Int. 12. The curves are anywhere between those two extremes?

A. Well, I say the shortest is four degrees; that is, 1,432 feet. The other stations would not average much more than a degree and a half; that is, 4,000 feet. They are all slight curves.

WILLIAM H. RUSSELL.

Deposition of F. D. Adams, taken at Springfield, Mass., July 31, 1872.

Direct examination by S. M. Whipple:

Int. 1. What is your name, age, residence, and occupation?

1840 A. My name is F. D. Adams; age, 50; residence, Springfield; occupation, car-builder.

Int. 2. For what railroad company?

A. The Boston and Albany.

Int. 3. Have you acted in the capacity of car-builder for any other company? and, if so, please state for what company.

A. I have been in the employ of the Buffalo and Erie road for about ten years, in charge of the car department; I have also been in charge of private car shops for some ten years.

Int. 4. How many years altogether have you been connected with car building?

A. About twenty-five or twenty-six years, about twenty of which I have been in charge of the work.

Int. 5. Do you build passenger cars at the Springfield shops of the Boston and Albany Railroad?

A. We do.

Int. 6. When were cars No. 123 and No. 124 finished and put to service?

A. No. 123 was built in October, 1871, and No. 124 in November, 1871; and No. 123 was put immediately on the track and went to running in October, and No. 124 commenced running in the early part of December.

Int. 7. What is the weight of cars No. 123 and No. 124?

A. The whole entire car, running gear and all, about twenty-two tons and a half.

Int. 8. What kind of wheels was applied to those cars when they were new?

A. We use a steel-tired wheel altogether on all of our passenger cars. We use four-wheel trucks mainly. There are four-wheel trucks under those two cars you speak of.

Int. 9. Are the cars still running on the road, with the same wheels, or steel-tired wheels?

A. Yes, sir.

Int. 10. At what time were cars No. 123 and No. 124 put into regular service in the train?

A. Well, they were put to running together about December 8, I think. They had run a little before that. No. 123 had run a little before;

1841 but I think the first service done by No. 124 was in this case where they were put in the same train together. It had made perhaps one or two trips out on the road.

Int. 11. At the time No. 123 was put to service in the train, what kind of brake was applied to it, when the two were put together?

A. At the time they were put together, No. 123 had the Tanner brake, I think.

Int. 12. Please look at "Defendants' Exhibit, large Tanner brake, 123," and state whether it correctly represents the size of levers, the proportion of levers, the size of windlass wheel, and the size of shaft on which the chain winds, put upon said car No. 123.

A. I should think they were about the same proportion. The fulcrums were 6 inches, and the long arm on the truck levers was 27 inches. The levers are arranged in the same manner. The wheel was 16 inches in diameter. That is the same size wheel we use—a 16-inch wheel. The shaft on which the chain winds is an inch and a half. That is the same size.

Int. 13. Then, in all respects it is the same as was applied to car No. 123?

A. I should think it was. It is applied in the same manner, and has the same length of levers.

Int. 14. What is the extreme length of the centre-lever?

A. Four feet. That is a fac-simile of what was used on No. 123, both in style and proportion.

Int. 15. Please look at the shoes lying about the exhibit, and state whether they are the shoes used by your road on that car; and state the weight.

A. It is the same pattern of shoe. The weight is 29 pounds.

Int. 16. What is the weight of iron applied to the whole car?

A. The weight of shoes applied to the whole car is 232 pounds.

Int. 17. Now look at "Defendants' Exhibit, large Springfield brake, 124," and state whether it is a correct representation of the brake, as applied to car No. 124, when it was put to service in the train.

1842 A. I should think it was put up in the same manner.

Int. 18. Are the levers the same proportion as in No. 123?

A. I think they are, from appearance. The long arm was about 27 inches, and the short arm 6; and the wheel was the same size we use on all our cars—16-inch wheel; and the "twister," the base of the windlass shaft, was an inch and a half. The "twister" we call it, most generally.

Int. 19. Please state whether or not the levers were placed, as represented, upon the outside of the brake-bars.

A. They were.

Int. 20. And also upon the outside, as seen in "Exhibit, large Tanner brake, 123?"

A. Yes, sir.

Int. 21. Then, if I understand you, the levers and the proportion of the levers are the same in "Exhibit, large Springfield brake, 124," and "Exhibit, large Tanner brake, 123?"

A. Just the same.

Int. 22. Can you prove it by the scales?

A. I presume so. I see the scales are attached there.

Int. 23. Please wind up the 16-inch windlass upon the "Defendants' Exhibit, large Tanner Brake, 123," until the scales indicate 48 pounds on each truck, and put down the dog in the rachet on the windlass wheel. (The witness did as requested.) Now you will please take "Exhibit, round scale," and apply it to the periphery of the wheel, and state how many pounds it takes to relieve the dog from the ratchet.

A. Just two pounds to throw the dog out. They are just alike.

Int. 24. Will you state the number of pounds pressure indicated by the scales in each truck when you begin to wind up the windlass as it stands?

A. Well, that is 16 pounds.

A. Probably they would not average more than 4,000 feet. They are on slight curves, most of them.

Int. 12. The curves are anywhere between those two extremes?

A. Well, I say the shortest is four degrees; that is, 1,432 feet. The other stations would not average much more than a degree and a half; that is, 4,000 feet. They are all slight curves.

WILLIAM H. RUSSELL.

Deposition of F. D. Adams, taken at Springfield, Mass., July 31, 1872.

Direct examination by S. M. Whipple:

Int. 1. What is your name, age, residence, and occupation?

1840 A. My name is F. D. Adams; age, 50; residence, Springfield; occupation, car-builder.

Int. 2. For what railroad company?

A. The Boston and Albany.

Int. 3. Have you acted in the capacity of car-builder for any other company? and, if so, please state for what company.

A. I have been in the employ of the Buffalo and Erie road for about ten years, in charge of the car department; I have also been in charge of private car shops for some ten years.

Int. 4. How many years altogether have you been connected with car building?

A. About twenty-five or twenty-six years, about twenty of which I have been in charge of the work.

Int. 5. Do you build passenger cars at the Springfield shops of the Boston and Albany Railroad?

A. We do.

Int. 6. When were cars No. 123 and No. 124 finished and put to service?

A. No. 123 was built in October, 1871, and No. 124 in November, 1871; and No. 123 was put immediately on the track and went to running in October, and No. 124 commenced running in the early part of December.

Int. 7. What is the weight of cars No. 123 and No. 124?

A. The whole entire car, running gear and all, about twenty-two tons and a half.

Int. 8. What kind of wheels was applied to those cars when they were new?

A. We use a steel-tired wheel altogether on all of our passenger cars. We use four-wheel trucks mainly. There are four-wheel trucks under those two cars you speak of.

Int. 9. Are the cars still running on the road, with the same wheels, or steel-tired wheels?

A. Yes, sir.

Int. 10. At what time were cars No. 123 and No. 124 put into regular service in the train?

A. Well, they were put to running together about December 8, I think. They had run a little before that. No. 123 had run a little before;
1841 but I think the first service done by No. 124 was in this case where they were put in the same train together. It had made perhaps one or two trips out on the road.

Int. 11. At the time No. 123 was put to service in the train, what kind of brake was applied to it, when the two were put together?

A. At the time they were put together, No. 123 had the Tanner brake, I think.

Int. 12. Please look at "Defendants' Exhibit, large Tanner brake, 123," and state whether it correctly represents the size of levers, the proportion of levers, the size of windlass wheel, and the size of shaft on which the chain winds, put upon said car No. 123.

A. I should think they were about the same proportion. The fulcrums were 6 inches, and the long arm on the truck levers was 27 inches. The levers are arranged in the same manner. The wheel was 16 inches in diameter. That is the same size wheel we use—a 16-inch wheel. The shaft on which the chain winds is an inch and a half. That is the same size.

Int. 13. Then, in all respects it is the same as was applied to car No. 123?

A. I should think it was. It is applied in the same manner, and has the same length of levers.

Int. 14. What is the extreme length of the centre-lever?

A. Four feet. That is a fac-simile of what was used on No. 123, both in style and proportion.

Int. 15. Please look at the shoes lying about the exhibit, and state whether they are the shoes used by your road on that car; and state the weight.

A. It is the same pattern of shoe. The weight is 29 pounds.

Int. 16. What is the weight of iron applied to the whole car?

A. The weight of shoes applied to the whole car is 232 pounds.

Int. 17. Now look at "Defendants' Exhibit, large Springfield brake, 124," and state whether it is a correct representation of the brake, as applied to car No. 124, when it was put to service in the train.

1842 A. I should think it was put up in the same manner.

Int. 18. Are the levers the same proportion as in No. 123?

A. I think they are, from appearance. The long arm was about 27 inches, and the short arm 6; and the wheel was the same size we use on all our cars—16-inch wheel; and the "twister," the base of the windlass shaft, was an inch and a half. The "twister" we call it, most generally.

Int. 19. Please state whether or not the levers were placed, as represented, upon the outside of the brake-bars.

A. They were.

Int. 20. And also upon the outside, as seen in "Exhibit, large Tanner brake, 123?"

A. Yes, sir.

Int. 21. Then, if I understand you, the levers and the proportion of the levers are the same in "Exhibit, large Springfield brake, 124," and "Exhibit, large Tanner brake, 123?"

A. Just the same.

Int. 22. Can you prove it by the scales?

A. I presume so. I see the scales are attached there.

Int. 23. Please wind up the 16-inch windlass upon the "Defendants' Exhibit, large Tanner Brake, 123," until the scales indicate 48 pounds on each truck, and put down the dog in the rachet on the windlass wheel. (The witness did as requested.) Now you will please take "Exhibit, round scale," and apply it to the periphery of the wheel, and state how many pounds it takes to relieve the dog from the ratchet.

A. Just two pounds to throw the dog out. They are just alike.

Int. 24. Will you state the number of pounds pressure indicated by the scales in each truck when you begin to wind up the windlass as it stands?

A. Well, that is 16 pounds.

Int. 25. Is it 16 pounds in each truck?

A. Yes, sir; it stands at 16 pounds.

Int. 26. When you wound up the windlass to 48 pounds or thereabouts, did it indicate the same pressure in each truck?

1843 A. It did.

Int. 27. You will now please look at "Defendants' Exhibit, large Springfield brake, 124," and state what the scales indicate.

A. That stands at 16 pounds; as near that as you can say; and this is the same. They both stand at 16.

Int. 28. The scales in each truck indicate the same?

A. Yes, sir; the same pressure.

Int. 29. You will now please wind up the 16-inch-diameter windlass until the scales in each truck indicate 48 pounds, and put down the dog in the ratchet. (Witness complied with the request.) Do the scales indicate 48 pounds in each truck?

A. Yes, sir.

Int. 30. You will please now apply "Exhibit, round scale," to the periphery of the 16-inch wheel, and state how many pounds it takes to relieve the dog from the ratchet.

A. Well, it is two pounds, as near as you can get it. Two pounds lets it off.

Int. 31. From these data, what is the ratio of the power applied to the brake-wheel to the power conveyed to the brakes of each truck?

A. As one is to 24; as one pound of power on the brake-wheel will carry 24 pounds on to each truck.

Int. 32. Can you say the same of "Defendants' Exhibit, large Tanner brake, 123"?

A. Yes, sir; the same; they are just equal.

Int. 33. It would seem from the foregoing, that all the conditions for applying friction force to the wheels of car No. 123 and car No. 124 are the same. Is that so?

A. Yes.

Int. 34. Were these cars coupled together and run over the same road, making the same stops under the brakes?

A. Yes; they were.

Int. 35. State whether, in your judgment, the two brakes ought to consume the same, or about the same, amount of iron to do the same work.

A. I should think they would, with the same power applied.

1844 Int. 36. Into whose train were these cars put?

A. They were put into Conductor Clark's train.

Int. 37. Where run?

A. From Springfield to Boston and return.

Int. 38. How often?

A. The round trip every day.

Int. 39. How many stops did "Defendants' Exhibit, Tanner brake, 123," make, as reported to you by M'r Clark, the conductor?

A. No. 123 made 1,521 stops—47 stops a day.

Int. 40. How much iron was consumed to make that number of stops?

A. 76 pounds.

(Plaintiff objected to this and the previous answer as hearsay.)

Int. 41. Who was instructed to keep account of the weight of iron consumed by the different brakes?

A. M'r Benjamin Ray, our inspector in Boston.

Int. 42. What number of pounds did he report to you were consumed in making 1,521 stops?

A. He reported to me, also, that they consumed 76 pounds on No. 123.

(Plaintiff objected to the answer as hearsay.)

Int. 43. Have the shoes worn out on each car been preserved?

A. They have.

Int. 44. By whom?

A. By M'r Ray; and sent to me.

Int. 45. Can they be produced?

A. Yes, sir; they are here.

Int. 46. Where are the shoes worn out on M'r Clark's train, on car No. 123?

A. Those are the shoes, piled up on the box.

Int. 47. You will please now look at "Defendants' Exhibit, large Springfield brake," and state how many stops were made by it in M'r Clark's train.

1845 A. No. 124 was reported to have made 1,479 stops.

Int. 48. And how much iron was it reported to you that the brake consumed, in making that number of stops?

A. That car consumed 77 pounds of iron.

Int. 49. And how many stops a day?

A. Thirty-four. I have stated that these cars were run together. As it stands now it looks an utter impossibility for one car to make more stops than another if they were kept coupled together all the time. My trouble was, that my testimony would look a little mixed here, making the statement that one car made more stops than the other, and yet, at the same time, making the statement that they were coupled together all the time.

Int. 50. Will you please explain that matter, as you understand it?

A. The reason why one, No. 123, was required to make more stops than the other was, it was run in an accommodation train from Boston to Worcester, and made all the stops; whereas in coming back from Boston to Worcester No. 124 was run in an express train, and only made part of the stops. They went down coupled together, and came back in separate trains, from Boston to Worcester; the one running as accommodation, the other as express; then they were again coupled together, coming to Springfield.

Int. 51. This experiment being completed, what was further judged best to do in the way of determining the actual capacity of these brakes to control their respective cars, in stopping the trains in which they were run?

A. Well, in order to ascertain precisely, and without any question as to their capacity or power of wear, we thought it best to get out some shoes that were all melted in the same cupola at the same time, the same puddle of iron, in order to have the iron all of the same density, all equal. We had some heads made for each car, and they were put on, by my order, to 123 and 124.

Int. 52. Why was it thought best to have the shoes for each car cast from the same cupola, or puddle of metal?

A. There was a possibility that this iron might not be all of the
1846 same hardness, the same density. We all of us understand per-
fectly well that iron varies in its density, and soft iron would
wear faster than hard iron would; and in order to make the thing per-
fectly sure, so that the iron would be equal in hardness, we were par-
ticular to get two sets of shoes out of the same lot of iron.

Int. 53. Into what train were those cars then put, for a second experiment?

A. They were put into M'r Jennings' train.

Int. 54. And from what place did they start, and to what point did they run?

A. They ran over the whole line of the road, from Boston to Albany.

Int. 55. When did the same train return?

A. The next day. It went up one day and down the next.

Int. 56. Who were the conductors on the train?

A. M'r Jennings, from Boston to Springfield; and M'r John B. Adams, from Springfield to Albany.

Int. 57. And who on the return?

A. On the return, M'r Charles Marsh, from Albany to Springfield; and M'r Jennings, from Springfield to Boston.

Int. 58. How long were the cars run in that train before the shoes were worn out?

A. No. 124 ran from January 30th to March 27th; No. 123, from January 30th to March 25; No. 124 having been taken out of the train, for some cause, two days. I can't call to mind now precisely what called it out; but it was out under some repairs; something was to be done to it that held it two days, and it was not run for that time; consequently, it was run two days more, to make the wear of the shoes and the number of trips equal.

Int. 59. At that time, was it judged proper to renew the iron?

A. Yes, sir; then M'r Ray had the heads renewed, or considered them worn out.

Int. 60. What report did you receive from M'r Ray, as to the weight of iron consumed in the time specified?

A. On No. 124, the weight of iron consumed was 81 pounds; on No. 123, it was 80 pounds.

1847 Int. 61. What was the weight of each shoe at the time of application?

A. The same as before stated, 29 pounds.

Int. 62. And the whole amount on each car?

A. 232 pounds. The shoes were cast from the same pattern, all of them.

Int. 63. That each car might take the grades alike, east and west, how was the train made up at Boston?

A. Well, it was thought best, and reported to me to have been done, to so arrange the cars in the train that one would go behind one day, and the other the next.

Int. 64. That is, No. 123 would go in the rear of the train one trip?

A. Yes, sir; and No. 124 the next trip, in order to give perfect equality in the wear of the brakes. It was thought there might be some inequality in the grades, thus giving one an advantage over the other. To obviate that, we thought it best to have them changed; and every time the train went to Boston, they were reversed.

Int. 65. After the completion of this second experiment, what disposal was made of the Tanner brake, on car No. 123?

A. After those shoes had been worn out, we took the Tanner brake off and put the old Springfield brake on No. 123; in other words, made it the same as No. 124.

Int. 66. In making the change to the old Springfield brake, what parts were retained for further use in car No. 123, and what parts discarded?

A. Well, we discarded the centre lever, and used the same truc levers and the same brake shaft. Everything was used except the centre lever.

Int. 67. Discarding the centre lever, what additions were made, in order to complete the Springfield brake ?

A. Nothing, except connecting the levers with the "twister," and adding two more levers. We used the same levers and added two more, and discarded the centre lever.

Int. 68. The two added were the same as those seen in "Defendants' Exhibit, old Springfield brakes," connected directly with the windlass ?

1848 A. Yes, sir, the same as the others.

Int. 69. The brake having been changed on car No. 123 from the Tanner brake to the old Springfield brake, what was it judged best to do to further test the capacity of the old Springfield brake ?

A. We put the old Springfield brake under the whole train, which consisted of three additional cars besides these two—five cars.

Int. 70. And where did you continue to run the train ?

A. We run the same train that had run previously from Boston to Albany, and has run ever since.

Int. 71. And is run at the present time ?

A. And is run at the present time in the same manner.

Int. 72. I think you have stated that this train leaves Boston every other day for Albany ?

A. Yes.

Int. 73. What train is run in connection with it on alternate days, and what brakes are applied to it ?

A. I don't know as I can give the numbers of the cars precisely. There is a train that corresponds to this that runs on opposite days, the cars of which are fitted up with the Hodge brake.

Int. 74. And run by the same conductors ?

A. Yes, sir; and by the same engineers, and manned by the same crew of brakemen.

Int. 75. Please state, if you know, how many sets of shoes have been worn out on No. 123 and No. 124 since the old Springfield brake was applied to all the cars of the train ?

A. This is report, too. I don't, of course, put on the shoes myself. It is reported by M'r Ray that two sets of shoes have been worn out, and we are on the third set, since the set that has been referred to was taken off, and the whole train fitted up with the Springfield brakes.

Int. 76. What time was the second set of shoes taken off ?

A. They were put on January 30th, and taken off of No. 124 March 27th, and from No. 123 March 25th.

Int. 77. Previous to that time, the whole train had been equipped with the old Springfield brakes ?

1849 A. No. The two sets of shoes of which the weights have been given were worn out before we put the old Springfield brakes on the whole. After these sets of shoes were worn out, we immediately fitted up the train.

Int. 78. You have worn out two sets since March 27th, and are on the third ?

A. Yes, sir.

Int. 79. After the brake on No. 123 was changed from the Tanner brake to the old Springfield brake, how much iron was consumed on said car and by said brake before it came to shoeing again, as reported to you by M'r Ray, the inspector of cars at Boston ?

A. I have no report of that, I think.

Int. 80. Has any accident happened to the train since it depended entirely on this brake to stop it, to your knowledge?

A. No; there has not.

Int. 81. No complaint has been made to you of the chains overlapping each other when the brake is applied?

A. I never have heard any complaint in relation to it. I might modify that perhaps a little. I have frequently inquired of the brakemen, on the passage through the depot here, how the brakes were working; and I think, in one instance, one of the brakemen said that the brake on No. 123 did not take hold well, or didn't work well; and I gave him directions to call the attention of the inspector at Albany—he was going west—to it, and have it taken up a little; the brake was a little slack. I presume he did so, for the next day he told me it was working well. That was the only instance in which I have ever heard any complaint in relation to it, that I recollect of. There has never been any complaint brought to me; that is, nobody has taken any pains to make any complaint. This was on account of my questioning him.

Int. 82. There has been no complaint about the old Springfield brake not holding as well on a curve as on a straight track, or vice versa?

A. I never have heard any.

1850 Int. 83. Please look at "Defendants' Exhibit, large Tanner brake, 123," and state by what means the power is divided and equalized between the brakes.

A. It is done by the centre lever.

Int. 84. Please now look at "Defendants' Exhibit, large Springfield brake," and answer the same question?

A. That is done through the brake shaft—done by the connecting rods.

Int. 85. By what means is this equality to be preserved, from time to time, as the brake-shoes wear away in Exhibit No. 123?

A. By taking up the lower connection.

Int. 86. And how is it in No. 124?

A. In the same way.

Int. 87. On how many bars do you have to take the wear up in No. 123, and how many in No. 124?

A. You have to take up on the same number in each. You have to take up two rods on No. 124, and only one rod on No. 123. You might say you have to take up on one bar on one, and two bars on the other.

Int. 88. Is it necessary on both brakes that the wear of the shoes should be taken up uniformly?

A. Yes, sir, certainly.

Int. 89. Why should it be taken up uniformly?

A. In order to convey the power uniformly between the two brakes.

Int. 90. What applies to one applies to the other, so far as taking up the wear of the shoes is concerned?

A. Yes, sir, certainly. (Plaintiff objected to the question as leading.) It is certainly very clear to any one who will look at the thing, or knows anything about it. It matters very little which way the question is put.

Int. 91. In applying either of these brakes (I refer to "Defendants' Exhibit, large Tanner brake, 123," and "Defendants' Exhibit, old Springfield brake, 124"), does it or not in any way change the character of the brake, if the truck-levers are put inside the bars instead of outside, the same as seen in both exhibits?

A. No, I think not.

1851 Int. 92. Does it or not change the character of either brake, if the levers are put upon the brake-bars in the manner seen in "Defendants' Exhibit, Springfield tender brake?"

A. No, it does not. The power is applied in the same way. The amount of power is just the same. It does not alter the character of the brake. It does not change the amount of power applied, that I can see.

Int. 93. Does it or not change the character of either brake if the levers are put upon the brake-bars in the manner seen in "Defendants' Exhibit, old single brake?"

A. No. I don't see that it would make any difference whether the fulcrum was made in the bar or in the lever. You can put the lever inside or out in that, and it would not change the relation at all.

Int. 94. Please look at "Defendants' Exhibit, old Springfield brake, 124," and state whether or not it changes the character of the brake to unite the levers in each truck with each other and with the windlass of the car by one chain instead of two, the same as seen in "Defendants' Exhibit, old Springfield tender brake."

A. No; I don't see as that changes its character at all. You get the same power from it on both trucks with one chain that you do with two, precisely. The amount is just the same.

Int. 95. What must be done to this Springfield tender brake to make it operative as a car brake from either end of the car?

(Plaintiff objected to the question.)

A. Put another lever into each truck, and connect them with a windlass at the other end, would make it operative as a car brake.

Int. 96. You will now please look at "Defendants' Exhibit, large Tanner brake, 123," and detach one truck-lever from the centre lever, and then wind up the smaller windlass wheel until the scales in the trucks indicate 48 pounds, and then apply "Exhibit, round scale," to the periphery of the smaller brake-wheel, and state how many pounds it takes to lift the dog from the ratchet, it having been put down when the scale indicates 48 pounds.

1852 A. Well, it is just a hair short of two pounds.

Int. 97. From these data, state whether the smaller, or 12-inch brake-wheel, will apply any more power to one truck than the 16-inch wheel to both trucks.

A. I don't see any difference. The scales show that it is the same.

Int. 98. Which, in your judgement, would produce the most sliding wheels, under the circumstances named, the single truck brake, with the smaller windlass, or the double truck brake, with the larger windlass?

A. I don't think there would be any difference. If the single brakes were fitted with a 12-inch wheel and the double brake with a 16-inch wheel, they would be perfectly equal; the eight wheels would slide as quick as the four wheels. Of course, that is presuming that the brakes are in good order all round.

Int. 99. Which brake, in your judgment, would have the greatest retarding power, to stop a car in motion, 500 pounds communicated to the wheels through a windlass on one truck, or the same number of pounds spread over two trucks, making 250 pounds in each truck?

A. I don't think there would be any difference.

Int. 100. What is your reason for this conclusion?

A. Well, the momentum of the train is stopped by the power applied to the car, whether it is at one point or eight points, or four points or eight points.

Int. 101. Then it makes no difference whether you apply the power to four wheels or eight wheels, so long as they continue to roll on the rail?

A. No; it don't make a particle of difference, in my opinion.

Int. 102. What, then, is the advantage of a double brake over a single brake?

A. So far as retarding or stopping the train is concerned, with the same power used, it would not make any difference, provided you don't slide the wheels. If you put the same power on the one that you do on the two, and no more, and the wheels do not slide, why, there is no difference in them at all, that I can see.

1853 Int. 103. On the journals of car wheels, do you deem it according to the weight of the car, or according to the surface of the bearing of the journals, that friction is developed?

A. Well, we suppose that the friction caused on the journals is according to the amount of weight carried. There is no more friction on a long journal than there would be on a short one, with the same weight. Nothing is added to its friction by spreading it over more surface, beyond what it has on a less surface, with the same weight.

Int. 104. Does the same rule apply to the application of power to the wheels, through the brakes, to generate friction?

A. I should think it did.

Int. 105. To what extent is the Tanner brake now used, so far as your observation and knowledge extend?

A. Well, I have not seen the Tanner brake used, in my travels, anywhere for a good many years, except where I have put it on here.

Int. 106. To what extent are you acquainted with the use of brakes in the United States?

A. Well, I have put on all these different kinds of brakes that are in general use; this single brake, the Stevens brake, the Hodge brake, the Tanner brake.

Int. 107. Please state what brake has superseded the Tanner brake.

Q. I think the Hodge brake has come into general use throughout the country. It is the one most generally used.

Int. 108. What other brake is in quite general use in different parts of the country?

A. Well, the Stevens brake is used; I don't know but possibly it may be used as much as the Hodge brake, but I think not.

Int. 109. What is the weight of the train of cars on which the old Springfield brake is used, including the weight of engine, tender, passengers, and baggage?

A. I should put it about one hundred and fifty tons, the five cars, engine and tender. Of course we have got to approximate it.

1854 Int. 110. Which brake, in your judgment, is the best, the old Springfield brake, the Tanner brake, or the Hodge brake? Whatever your answer may be, please give the reason.

A. Well, the Hodge brake is the best brake, unquestionably. The reason of it is, it equalizes better, and requires less attention to keep it in good working order than either of the others.

Int. 111. Wherein does the application of the Hodge brake on the cars on your road differ from the application of the Springfield brake in the matter of size of shaft on which the chain is wound, length of levers in the trucks, and the hanging of the brakes to the wheels?

A. It differs materially. The base of the twister first winds up on a cast-iron worm, that is three inches in diameter at the top and about two at the bottom. The effect is to take up the slack quick, and apply the power at the bottom, the twister on the Springfield brake being only an inch and a half in diameter and straight. The upper part in the Hodge brake is supposed only to take up the slack chain, the lower part to apply the power. The fulcrum of the levers is an inch more than in the old Springfield brake; the short arm is seven inches instead of six. The link upon which the head is fastened to the arm of the truck, is, I think, about an inch and a half shorter on the Hodge brake than on the old Springfield brake.

Int. 112. What advantage, if any, does the dropping of the brakes toward the track have in holding the car?

A. It is generally believed among mechanics, although I am not able to give a positive reason for that, that the further under, or the nearer the track, we run our shoes, the more power we get. In other words, it is more effective in its grasp of the wheel. It will slide the wheel quicker to throw the shoe down under the wheel than it will to bring it up nearer the centre of the wheel.

Int. 113. What is the object of increasing the size of the shaft on which the chain winds in the Hodge brake, and als oin lengthening the short arm of the lever and lifting the brake bars from the track?

1855 A. If we gave it the same purchase that this old Springfield has, we should give it too much power on the wheels, and slide them. Consequently, we must reduce the power at some point, and we take the way we have taken to accomplish that. It could be accomplished in any other way. You might reduce the size of the brake wheel and it would effect the same thing; or decreasing the long arm of the lever would effect the same thing. The object is to decrease the power; we have got too much leverage.

Int. 114. Please look at the Tanner patent-office model, and note the point of connection of the truck-levers with the centre lever, and state whether this brake, when applied to the car as indicated in the model it should be, would apply more or less power to the brake-bars of each truck than the same brake will when attached to the lever of one truck.

A. Put up in this manner, it would have a great deal more power than it would attached to the lever of a single truck.

Cross-examined by S. D. Cozzens, esq., for plaintiff:

Cross int. 1. How long have these features in the arrangement of the Hodge brake, of which you have just spoken, been in use upon the Boston and Albany Railroad?

A. I cannot tell. They have been in use ever since I have been here.

Cr. int. 2. How long is that?

A. I have been here two years and four months. I found them in these same proportions in which they are now being used. In other words, I have not altered the proportions at all. That is the general arrangement. It is put on everywhere, to my knowledge. I am familiar with the use of the brake on other roads.

(It is agreed that these same features in the arrangement of the Hodge brake, of which M'r Adams has spoken, have been in use on the Boston and Albany Railroad since the first introduction of the Hodge brake on that road.)

Cr. int. 3. If you were at liberty to use either the Springfield brake, the Tanner brake, or the Hodge brake, as you might prefer, would you choose the Hodge brake?

1856 A. I should, most certainly.

Cr. int. 4. Were you present last Saturday with M'r Sayles; and did you see the Springfield brake applied on car No. 4, on the Connecticut River Railroad; and did you see the link of the chain catch on the eye of the windlass; and did you see said chain wind spirally around the windlass shaft when the brake was applied?

A. Yes, sir; I did.

Cr.-int. 5. Did you see the chains at both ends of the car catch?

A. Yes, sir. The eye-bolt that goes through the shaft; the link in which the eye is welded, doubled over on the eye one turn of the link, or lopped down—you might express it that way. Instead of pulling out straight, it fell down, and fell down on the outside of the eye. That is what it did, exactly; no uncommon thing. It is almost universal with that kind of twisters. It would do it on the Hodge brake, or any other brake. It will do the same thing on that same kind of stem, understand, but not on a cast-iron worm.

Cr.-int. 6. When you say "that kind of stem," you mean such a stem as is shown in Defendants' Exhibit, Large Springfield Brake, 124?

A. Yes, sir; I mean that.

Cr.-int. 7. Are the stems of all the Springfield brakes you now have on your cars like said exhibit?

A. I think they are.

Cr.-int. 8. How much does that "lopping down" of the chain, as you call it, instead of winding straight round the stem, take up the chain?

A. Well, the links, I suppose, are about an inch and a half long. It would not take it up over the length of the link, and I don't think it would take up the length of the link—that simple dropping down of one link.

Cr.-int. 9. When the chain winds spirally around the stem, how much would that take up the chain as compared with its winding straight?

A. That would depend altogether upon how spirally it wound. If the chain was very slack, it would spiral more, and of course take up faster.

1857 Cr.-int. 10. In other words, the more it spiralled, the more it would take up?

A. That is true. The more slack there was, the more it would spiral.

Cr.-int. 11. Assuming that in this two-chain Springfield brake one of the chains, from any cause, wound unequally as compared with the other, would not the application of the brake be different upon one truck from what it was upon the other?

A. Not necessarily.

Cr.-int. 12. I don't think you understand my question; I will put it again. Suppose, in this two chain Springfield brake, one of the chains begins to draw on the truck lever before the other one does, will not then the application of the brake be unequal on the two trucks?

A. M'r Cozzens, I can't answer that directly, without an explanation. I should answer it just as I did before—it would not necessarily apply the power unequally. But I say it needs explanation. I claim, just as I did before, that just as quick as one chain is taut it will wind straight around the twister; as long as either is slack, it will spiral, and take up faster, until the chains are equalized in length, and then they will both pull together.

Cr.-int. 13. Question repeated.

A. Well, I would modify my answer so much as this, that if there was an extreme amount of slack it would not be equal; but if there was only what would ordinarily occur in the natural wear of the brakes, I claim that there would not be any material difference.

(The question was once more read to the witness, and he answered, "It would make the power unequal.")

Cr.-int. 14. What do you know about what stops were made, as stated by you in your answer to the 34th direct question, except by hearsay?

A. I don't know anything about it, only by hearsay.

Cr.-int. 15. How do you know that the shoes referred to in answer to the 43d direct question were preserved, except by hearsay?

1858 A. Only by the report made to me, as ordering the result reported to me.

Cr.-int. 16. The same thing is true, is it not, in regard to your answer to direct question 47?

A. The answers to all these questions were made by report.

Cr.-int. 17. The same is true in respect to your answer to direct question 48, as to the weight of iron consumed?

A. Yes; my answer to all those questions came by report. They all came from subordinates, who are supposed to be subject to my order.

Cr.-int. 18. What is the ground of your knowledge in reference to your answer to direct question 51?

(Question and answer read.)

A. I don't know as I know how to answer that exactly to suit you. I took part in the consultation as to what was best to be done. M'r Whipple consulted me about that matter; and in regard to the wear of iron, &c., M'r Whipple and myself judged that was best.

Cr.-int. 19. You had nothing to do with puddling the iron of which these shoes were made?

A. No, sir.

Cr.-int. 20. How do you know it was the same puddle of iron?

A. I only know by hearsay.

Cr.-int. 21. How do you know, even if it were the same puddle of iron, that each shoe made from it would be of the same density and hardness?

A. I don't know that; but most mechanics conclude that, when the metal is all taken out of one puddle of iron.

Cr.-int. 22. Don't you know that it often happens that, even in a lot of iron made at the same time, different portions of it differ materially in respect to density, hardness, and amount of carbon?

A. Yes, sir; if the plan is laid for that. I admit that, if it is prepared for it.

Cr.-int. 23. Without laying any plan for it, do you not know that it frequently happens so?

1859 A. No; I don't know that it frequently happens so.

Cr.-int. 24. Did you see the heads referred to in answer to direct question 54 put under the car?

A. No, sir; I did not.

Cr.-int. 25. Do you know, of your own knowledge, that the same shoes were continued under those cars all the time that what you call that experiment lasted?

A. No, sir; only by report.

Cr.-int. 26. How do you know what you stated in your 59th answer, except by hearsay?

(Question and answer read.)

A. That is hearsay, of course, as you call it—report.

Cr.-int. 27. The same thing is true, I suppose, in regard to your answer to direct question 60—about the weight of iron consumed?

A. All those questions are answered from the same knowledge.

Cr.-int. 28. The same thing is true, is it not, in regard to your answer to direct question 63—about how it was reported that the trains were made up, and so on?

A. Yes, sir.

Cr.-int. 29. Is or not the same thing true in regard to your answer to direct interrogatory 75—in reference to the number of sets of shoes worn out, &c.?

A. No; I don't know that it is. That was reported in the same way. Those shoes have been kept up at Boston.

Cr.-int. 30. The same thing is true in regard to your answer to direct interrogatory 76, is it not?

(Question and answer read.)

A. Yes.

Cr.-int. 31. The same is true in regard to your answer to direct interrogatory 78, is it not?

(Question and answer read.)

A. It is.

Cr.-int. 32. Are you able to state from your experience in car-building what was the diameter of windlass wheels when single brakes were used on passenger-cars, previous to the introduction of double-acting brakes on such cars?

A. Well, I am not familiar with what was used, or the size of the wheel. I cannot answer that question.

1860 Cr.-int. 33. Do you know whether it was frequently customary, when single brakes were used on passenger-cars, to have a single brake at each end of the car?

A. No, I don't know that. Double brakes have been used pretty generally ever since I became any way familiar with car building.

Cr.-int. 34. Have you lately discussed with M'r Whipple, or examined for yourself, any scientific books in reference to the law of developing friction?

A. No, I don't know that I have read any book that would be called a specially scientific book upon that question. I have read articles at different times in relation to it, but not with M'r Whipple.

Cr.-int. 35. Have you read or examined any book lately, whether you call it scientific or not?

A. I say I have read articles in reference to it.

Cr.-int. 36. No book?

A. No book.

Cr.-int. 37. What articles have you read; and where were they?

A. In railway papers.

Cr.-int. 38. What were the articles?

A. I don't know as I could define them, so as to be very definite.

Cr.-int. 39. Can you state any railway paper in which you have read such articles?

A. In the Railway Gazette we get articles of that kind occasionally.

Cr.-int. 40. How lately have you read any such article in the Railway Gazette?

A. Almost every week or two we have articles referring to that.

Cr.-int. 41. How lately have you read any such article?

A. I have not read anything in regard to it for two or three months, possibly.

Cr.-int. 42. Have you read any such article in the Railway Gazette, or any other paper, since these Springfield brakes have been running on the Boston and Albany R. R.?

A. Not that had a bearing specifically upon friction, that I know of. I have taken no pains to look up the matter.

1861 Cr.-int. 43. How long have you known what you have stated to be the law of the development of friction, namely, that it is in proportion to the weight rather than to the amount of surface?

A. Well, I should have to answer that that was the general opinion.

Cr.-int. 44. How long have you possessed it?

A. I don't know as I could go back to that. I have entertained the idea for a good many years. There are a good many facts that mechanics get, which they do not get from any special teaching, but from general knowledge, that we pick up. We do not profess to have a scientific education; but there are certain laws and theories that we are governed by in our operations.

Cr.-int. 45. Have you understood that to be the fact since about the commencement of your experience as car-builder?

A. For a good many years I have understood the fact, that weight and speed made friction. These two items combined are supposed to make friction in the main.

Cr.-int. 46. What I want to get at is, whether you have known that since about the time you commenced car-building?

A. Well, of course, I hope I have been learning some general matters all the time. I did not know so much, nor think so much about them, before I was placed in charge of the work as I have since; I had no occasion to.

Cr.-int. 47. As near as you can state, about how many years have you known it?

A. Say for fifteen years that idea has been prevalent in my mind as the law.

Cr.-int. 48. Did you ever know of a Springfield brake being in use on any railroad in the United States until within the last few months?

A. No, sir, I did not.

Cr.-int. 49. What is the length of the short chains and rods on the five cars on your road which have on the old Springfield brake?

A. On four of the cars the chains and rods are 3 feet 4 inches from the windlass-shaft to the first lever. On the other car they are 3 feet 8½ inches.

1862 Cr.-int. 50. About how long are the long chains and rods on said cars?

A. They are about 40 feet from the windlass to the lever, on cars Nos. 123 and 124. On the other three cars they are somewhat shorter, as the cars are shorter.

Cr.-int. 51. What is the length of the trucks of cars Nos. 123 and 124?

A. They are about 11 feet, and from centre to centre of axles, 7 feet.

Cr.-int. 52. Has your attention been called to several trucks of passenger-cars with regard to the swing-beam arrangements on said trucks? If so, please state what trucks they were, and how much longitudinal motion you found in said trucks.

A. My attention has been called to the trucks under passenger-cars Nos. 111 and 50. There was no material longitudinal play—a very little in 111, but not enough to make any difference. They had been built and run about two years. I saw another truck which had been run a number of years; I can't say how long. It was equally as tight. There was not perceptible wear in any one of the three trucks mentioned.

Redirect:

Int. 115. Do you wish to have it understood that the three pairs of trucks mentioned in your cross-examination represent a fair average of the longitudinal motion of other pairs of trucks on your road?

A. No; I don't think it is a fair average. As a general rule, I think there is more shrinkage and wear, hence more motion.

Int. 116. In comparing the trucks that you now build for the Boston and Albany Railroad, with the trucks that you built when you first became connected with railroads, what is the difference between the extreme lengths and between the centre of axles?

A. Four feet six inches and four feet eight inches used to be the common spread. We have old trucks on our road now, four feet eight inches, while our new trucks are seven feet. I allude to trucks of passenger-cars.

1863 Int. 117. What is the length of chains on the old Springfield brake, as seen on car No. 124? And what is the length of chain on car 123, same brake?

A. On 124, the chains are from thirty inches to three feet. On 123, the chains are only fifteen inches long. The same may be said of the other three cars.

Int. 118. Why this difference in the chains on 124 as compared with the other cars?

A. I can't account for that, only that the short chains have been put on since the car first went out; the chains have been broken, and a rod substituted for a portion of the chains. That is the only way I can account for it.

Int. 119. What disadvantage has the brake necessarily worked under on these cars having the short chains, in consequence thereof?

A. When the shoes have become well worn, the chain would be all taken up on the windlass, which would come in contact with the rod before you could get the power of the brake upon the wheel. The consequence was that the brake failed to hold as it should. That was the reason of one complaint that was made to me in relation to the brake. There has been no complaint that I ever heard of in relation to No. 124.

Int. 120. Have you taken any steps, or do you intend to, in relation to making a change in all the cars having the Springfield brake on, to make them comparatively of the same length?

A. Yes, I intend to have them all made the same as 124.

Int. 121. When that is done and the wear of the shoes is properly taken up, what must be the practical operation of the brakes?

(Objected to.)

A. I see no reason why they shouldn't hold as well as any brake. In fact, I think they do.

Int. 122. Have you examined the train of five cars on the Boston and Albany Railroad to see how the long and short connections of the
1864 old Springfield brake are attached to the windlasses at either end of the cars? If so, what is the result of your observations?

A. I have examined them, and find the long connection is connected with the windlass-shaft above, and the short one below, or exactly the reverse of the "Exhibit, large Springfield brake, 124." The connections on all five of the cars are alike and as already stated.

Int. 123. I wish further to call your attention to the subject-matter of generating frictions, and will inquire: In stopping a train of cars by means of the brakes, what may the friction be called by which it is done?

A. I should call it "rolling friction."

Int. 124. What may the friction be called that comes into action when the rolling friction ceases, if the car is still in motion?

A. "Sliding friction."

Int. 125. At what speed does sliding friction take place?

A. At very slow speed.

Int. 126. Will you please define the law of generating friction as applied to brakes?

A. The law of friction as applied to brakes is, that friction is wholly independent of the extent of surface in contact. The friction which accompanies motion is also independent of the velocity with which the body moves.

Int. 127. By whose authority do you state this law of friction; and upon what experiments is it founded; when were they made, and by whose order?

A. I learned this from a work written by W. H. C. Bartlett, LL. D., professor of natural and experimental philosophy in the U. S. Military Academy at West Point, entitled "Elements of Analytical Mechanics," published in 1854 by A. S. Barnes & Co., New York. The law is founded on experiments made by M. Morin, at Metz, in 1831, 1832, and 1833, by the order of the French Government.

Int. 128. Will you please quote from M. Morin's experiments, as introduced into D'r Bartlett's work, that it may be seen how slight is the variation between extreme pressures, surfaces and velocities?

1865 A. In these experiments, "the surfaces of contact were made to range in extent from 1 to 84; the forces which pressed them together, from 88 to 2,205 pounds; and the velocities, from the slowest perceptible motion to $9\frac{8}{10}$ feet per second; causing them to be at one time accelerated, at another uniform, and at another retarded; yet throughout all the wide range of variation, in no instance did the ratio of pressure to the friction differ from its mean value of 0.478 by more than $\frac{1}{24}$ of this same fraction."

Int. 129. The deduction from these experiments is what?

A. The deduction is that rolling friction is wholly independent of the extent of surface in contact, and that it is independent of velocity.

Int. 130. The deduction, as applied to double and single brakes, is what?

A. That the same pressure is equally effectual applied to two pair of wheels, in stopping a car, as when applied to four pair of wheels, provided the wheels do not slip or slide.

Int. 131. Assume that all double brakes are more or less unequal in applying the presure to the wheels of the car from the different inclinations of the levers, and from other causes; does such inequality in any way affect the retarding power of the brake, so long as the wheels continue to roll?

A. I don't think it does.

Int. 132. Wherein, then, is the single brake inferior to the double brake?

A. The single brake is less effectual to stop a car, just so far as it fails to generate friction enough to stop the car on time; and if the same power is applied to one truck as is applied to both, and no wheels are slid, the retarding force is the same.

Int. 133. Then, so far as stopping the car is concerned, a single brake is doing just as effectual service as a double brake under the same pressure, so long as the wheels under pressure roll; is that so?

(Objected to.)

A. Yes; that is my opinion.

Int. 134. Upon what law or fact do you base your opinion?

1866 A. Upon the law as laid down by D'r Bartlett, already referred to, based on the experiments ordered by the French Government, coupled with my own experiments.

Int. 135. Would or not a slight release of presure by the brakeman, just before the car stops, prevent the wheels from sliding?

A. I think it would.

Int. 136. In view of the foregoing statements and conclusions in relation to generating and applying friction to brakes as a standard of judgment, and allowing that three brakemen are necessary to a train of six cars—double brakes—how many brakemen would it require to make the same time in stopping the same train with single brakes?

A. I should think one additional man would handle the train ordinarily as well as the three would with the double brakes.

Int. 137. Have you consulted any other mechanical work on friction; if so, what work; by whom edited; where published, and by whom?

A. I have consulted a dictionary entitled a "Dictionary of Machines, Mechanics, Engine-work and Engineering," edited by Oliver Byrne, published in New York, by D. Appleton & Co., in 1850.

Int. 138. To what single proposition does Byrne reduce the whole doctrine of friction?

A. On page 707, under the article of Friction, he says: "The whole doctrine of friction may be reduced to the single proposition, that the friction is proportionate to the pressure upon the surfaces in contact, and independent of the extent of the surfaces and of the velocity of their motion."

Int. 139. On what experiment is this proposition founded?

A. On experiments conducted by the French Academy, conducted by M. Morin by order of the French Government.

Int. 140. What experiments in braking or stopping a car have you witnessed of late, verifying this proposition? Please answer fully in detail.

A. I witnessed yesterday an experiment on car N, on the Connecticut River Railroad. The first trial was with the Tanner brake, at a
1867 speed of about 30 miles an hour, as I estimated it. The car was stopped, being cut off from the engine in 510 feet from the point of application of the brake. We then made a second trial, by disconnecting one truck from the centre lever, thus reducing it to a single brake. Running at as near the same speed as possible, and under the same conditions, the engine cut off from the car at the same point, and the brake applied by the same brakeman in the same manner, the car was stopped six feet short of the point of stoppage on the first trial with the Tanner brake. We then, to make the thing more positive, made a third trial with the single brake, reconnecting the truck just mentioned and disconnecting the other truck, and at the same rate of speed, and all circumstances as nearly the same as possible, stopped at the same point as on the first trial with the Tanner brake. We then connected both trucks, and made a fourth trial with the Tanner brake, and under the same circumstances, and stopped at the same point of the first trial. The speed and circumstances were all, as nearly as possible, the same in all the trials.

Int. 141. Have these tests been made on the cars of different roads to ascertain how much longitudinal motion there is between the bodies of the cars and the trucks; if so, have you a knowledge of the same; how were these tests made; on what cars, and with what results?

A. There have been made such tests, and I have a knowledge of the same. They were made by myself and M'r Robert Hitchcock, of the Connecticut River Railroad. We secured one truck by blocking the wheels firmly, then by barring the other truck as far as possible toward the end of the car. Then we made a plumb-line from a point on the body of the car upon the side of the truck. Then we reversed the motion of that same truck, and barred it the other way under the car as far as possible; then dropped a plumb-line from the same point on the body of the car, as before, and made a line upon the truck, and found, upon Boston and Albany car No. 101, the motion was three-quarters of an inch; on New York and New Haven car No. 57, the motion was 1⅛ inches; same road, car No. 17, the motion was one inch; New York and Boston Express Line passenger car No. 23, the motion was 1868 1⅛ inches; Hartford and New Haven passenger car (excessively strained, being pressed against the head-block or snubbing-post at the end of the truck), the centre of the bolster was forced by the centre of truck from 3½ inches; Connecticut River Railroad car No. 3 there was two inches motion; same road, car "H," the motion was 1⅛ inches; same road, car "C," the motion was 1⅝ inches; Hartford, Providence and Fish. Railroad car No. 5, the motion was ¾ inch; same road, car No. 28, 1 inch motion; same road, car No. 26, ¾ inch motion; same road, car No. 7, 1 inch motion; same road, car No. 17, ¾ inch motion. We also made an experiment with an engine attached to Connecticut River Railroad car No. 3 (already referred to), and set the brakes as strongly as we could, and gave the motion ahead and held on. Then we made a plumb line, as before, from a given point on the body, and marked the side of the truck. We then gave the engine motion backward, and held on; and from the same point on the body of the car we dropped another line on the side of the truck, and found the motion 2½ inches.

Int. 142. Will you please look at the 52d cr. interrogatory and the answer to the same, and state whether you see anything therein that seems to conflict with the tests or experiments you have testified to?

A. I should say those trucks belonging to cars 50 and 111, and the other truck referred to in said answer, were the exception rather than the rule.

Int. 143. Had the other truck referred to been exposed to the weather and the timbers become swollen?

A. I shouldn't attribute it to that.

Int. 144. To what would you attribute the tightness in the parts pertaining to the swing-bolster of the truck, which had been run a number of years?

A. I cannot give any good reason. It is a very unusual thing to find the swing-bolster of an old truck without considerable space between bolster and cross-timbers.

Int. 145. What construction of truck gives the most longitudinal motion, and what least?

A. Trucks built with narrow bolsters will give more than those with broader ones.

1869 Int. 146. Which mode of construction was most in use ten years ago?

A. The narrow bolster; from 8 to ten inches wide, or just sufficient space to receive the springs. If elliptic springs were used—two, side by side—there would be required only about 8 or 9 inches timber.

Int. 147. What width of bolster is now in use upon passenger-cars of different roads, so far as your knowledge extends?

A. I can't tell exactly our width now from memory, but we are using four elliptic springs, side by side, which require double the width of the old style. Our opening between timbers is about 17 inches. The New York Central Railroad are putting into many of their cars six elliptic springs, side by side, necessarily requiring about 8 inches more space, which makes the opening about 2 feet. The New York and Erie Railroad, I am told, are adopting the four-spring mode.

Recross:

Cr.-int. 53. Were the trucks of the passenger-cars Nos. 50 and 111, and also the other truck referred to in your 52d cross-answer, trucks which belonged to the Boston and Albany Railroad Company; and was your attention called to them in the yard or shop of that company; and were they the only passenger-trucks which were about there at that time, which were not under cars?

A. My attention was called to them in the yard. I can't say positively whether there were other trucks there or not.

Cr.-int. 54. You don't remember seeing any other trucks there at that time?

A. No.

Cr.-int. 55. You have had a good deal to say about the law of friction. Will you please state whether the quotation you have made from Professor Bartlett's book and Byrne's dictionary contain all the matter upon which you rely, as respects those two books, for the conclusions you have stated?

A. Yes.

Cr.-int. 56. Suppose a car-brake to be proposed to you as a double-acting brake, and suppose that in that brake, after the parts had
1870 been so adjusted that the brakes would operate properly while the car was on a straight track, the natural tendency was, that when the car with the brakes applied passed from the straight track on to a curved track, it would cause the brakes of one truck to bind so hard as to slide the wheels of that truck, and would loosen the brake of the other truck; would such a brake be a practical one for use on railroads?

A. No; upon that supposition I don't think it would be considered so.

Redirect:

Int. 148. Is there any curve on the Boston and Albany Railroad, or any other road within your acquaintance, where the old Springfield brake,—for illustration,—if applied to a car and run upon said curve, would have the brake so applied as to slide the wheels in one truck, and let the brake loose on the other?

A. Not on the main line of any road.

Recross:

Cr.-int. 57. State upon what curves of the Boston and Albany Railroad, or of any other road, you have noticed the operation of the Springfield brake, when the car having it on was passing, with the brakes applied, from a straight track on to the curve; and state how such Springfield brake was arranged.

A. I have noticed the cars with the Springfield brake on, on the Boston and Albany Railroad, as they came down the grade into the Springfield depot, on the east side, on the curve from one track to the other, and did not see any perceptible difference in the pressure upon the trucks. I have noticed it when I have been on the trains, passing into Russell depot, for instance, and have never noticed any perceptible difference in the pressure upon the trucks. The curve at Russell is not a very sharp one. I don't call to mind any other curves that I have noticed the operation of the brake on. I haven't noticed the operation of the brake on any other than the Boston and Albany Railroad. The Springfield brakes that I have noticed were the same as "Defendants' Exhibit, 1871 large Springfield brake, 124," except the long chain and rod are above on the windlass-staff instead of below.

Cr.-int. 58. What is the radius of the curve you speak of, on the east side of the Springfield depot?

A. I couldn't tell; but the same that is ordinarily used in passing from one track to another on a double-track road, the inside rails of the two tracks being six feet apart.

Cr.-int. 59. The curve at Russell is quite a slight one, isn't it?

A. No; I shouldn't call it a very slight curve. I should call it a sharper curve than the one passing from one track to the other, just spoken of.

Cr.-int. 60. Is this curve just spoken of, between the two tracks, long enough to enable both trucks of a passenger-car to be on the same curve at the same time?

A. I should think not on the same curve; but one would be on the reverse curve. It is a reverse curve there, and one truck would be on one part of the S while the other was on the other part, if the car was entirely on the curves. But in passing on or off the curve one truck would be on the curve while the other was on the straight track.

Redirect:

Int. 149. Does the train of five cars, to which the old Springfield brake is applied, pass over this reverse curve under the brakes on its arrival from Boston; and is there any perceptible difference in the efficiency of the brakes while passing such curve?

A. It does pass over such curve every other day. I have never noticed any perceptible difference. I have noticed its passage over the curve several times.

F. D. ADAMS.

Deposition of E. S. Dudley.

Int. 1. What is your name, age, residence, and occupation?

1872 A. My name is E. S. Dudley; age, 38; occupation, machinist, working for the Boston and Albany Railroad, in the car-department.

Int. 2. Will you please state whether your attention was called to certain shoes that were produced by Mr Adams, master car-builder, and whether you were requested to put a certain mark on them, whereby you could identify them?

A. I was told to put a mark on them, or a certain mark, for a certain purpose.

Int. 3. Will you please look at "Defendants' Exhibit, brake-shoes, 124," and state whether you find them marked.

A. These are marked, all of them. I have looked them over.

Int. 4. How did you mark them?

A. I marked them with a chisel mark; a cross on the side.

Int. 5. In addition to that, did you put a private mark on?

A. I did.

Int. 6. What was that private mark?

A. The private mark is a centre-punch mark; "prick punch," I call it.

Int. 7. Do you find the cross and your private mark, the prick-punch mark, on each brake-shoe of car No. 124?

A. I do, sir.

Int. 8. You will now please look at the shoes purporting to belong to car No. 123, and see if you find the cross and also the prick-punch mark, which you say is your private mark.

A. I do. I find the cross on all, and the prick-punch mark on all except one; that was probably neglected. But the cross is on that one and I think it is the same.

Cross-examined by the complainant, M'r Tho's Sayles:

Cr.-int. 1. Do you know that these brake-shoes of which you have just spoken are the ones that were used on cars No. 123 and No. 124?

A. I was not familiar with what cars they were going on, nor for what purpose they were to be used. I was not informed of any of the
1873 particulars at all, only that I was to mark them so that I could
identify them in case I was called upon. They were brought into the shop and drilled, and then I was told to put a mark on them, so that I could identify them; and they were carried out to the depot and sent off.

Cr.-int. 2. Where was this marking done?

A. In the Boston and Albany car-shop here in Springfield.

Cr.-int. 3. Was that before the shoes had been used on the cars?

A. Yes, sir; they were new shoes.

Cr.-int. 4. Is it not possible that other shoes may have been marked in the same way, and substituted for those you marked?

A. I think not. I don't think they could have. They might, possibly, by taking pains. I think the marks on those are the same that I used. They show the same chisel-mark that I use in marking the cars.

Cr.-int. 5. Another chisel of the same kind would have made the same mark?

A. Yes, sir; if it was just like this one. For my own curiosity, I preserved the chisel just in the same state that it was when I marked them. I have not used the chisel since. I laid it away, so that it could not have been used. I can produce the chisel, if necessary.

Redirect:

Int. 9. Did you ever communicate to any one, until the present time, what your private mark was?

A. No, sir.

E. S. DUDLEY.

Deposition of John W. Clark.

Int. 1. What is your name, age, residence, and occupation?

A. John W. Clark; age, 35; residence, Springfield, Mass.; conductor on the Boston and Albany Railroad.

Int. 2. How long have you been a conductor?

1874 A. About seven years, I think.

Int. 3. What train do you run as conductor?

A. It is known here as the morning accommodation train.

Int. 4. And it runs to what place?

A. To Boston. On the lower end of the road it is known as No. 50. We go by the numbers there.

Int. 5. And it returns when?

A. In the evening here; due here at 7 o'clock.

Int. 6. Please state, if you know, when cars No. 123 and No. 124, of the Boston and Albany Railroad, were put to service in your train.

A. The 12th of December, 1871, they commenced running regularly. I ran No. 124 one trip, I think, trying the car, or something, and then took them on regularly.

Int. 7. And ran them to what time?

A. I left them in Boston, at noon, the 29th of January, 1872.

Int. 8. Were they then taken out of your train?

A. They were, sir.

Int. 9. Had those cars been run in any other train?

A. No, sir; they were new cars. They might have been out on a trip trying them, but no regular service.

Int. 10. Please look at "Defendants' Exhibit, large Tanner brake, 123," and state whether it is a correct representation of the brake as applied to car No. 123, and run in your train.

A. It is just the same, for everything I can see; the model of it; connected in the same way.

Int. 11. You will now please look at "Defendants' Exhibit, large Springfield brake, 124," and state whether it is a correct representation of the brake applied to car No. 124, and run in your train.

A. It is.

Int. 12. Please state whether or no you kept count of the stops made by your train, so long as cars No. 123 and No. 124 were run in it.

A. I did.

Int. 13. How many stops did car No. 123 make, and how many stops did car No. 124 make, as kept by yourself?

1875 A. No. 123 made 47 stops each day, and No. 124 made 34 stops each day.

Int. 14. What was the whole number of stops made by No. 123?

A. No. 123 made 1,521 stops, and No. 124 made 1,479 stops.

Int. 15. You say that No. 123 made 47 stops a day, and No. 124 made 34 stops a day. Please explain why one car made more stops per day than the other.

A. In coming from Boston to Springfield No. 123 was run on a way train from Boston to Worcester; No. 124 came up on an express train, and they were coupled together at Worcester, and came from Worcester to Springfield together.

Int. 16. How many stops would No. 123 make on the way train to Worcester, and how many stops would No. 124 make on the express train to the same place?

A. I don't know as I can tell that.

Int. 17. It would be the difference between 34 and 47, would it not?

A. Yes, sir; of course it would. The express train makes only two stops—at the crossing and at Framingham. There were 13 stops more for the No. 123 car.

Int. 18. At what time were the shoes on No. 123 worn out, or considered as unfit for further use?

A. It was the 18th of January, 1872.

Int. 19. And on what day were the shoes on No. 124 worn out or considered as unfit for further use?

A. The 29th of January, 1872.

Int. 20. If I understand it, this difference of time in which the shoes were worn out in No. 123 and No. 124 was owing to the fact that No. 123 made 13 more stops a day than No. 124?

A. Yes, sir.

Int. 21. If I understand you, then, car No. 123 made 1,521 regular stops up to the 18th of January, and No. 124 made 1,479 stops up to the 29th of January?

A. Yes, sir.

Int. 22. In what part of your train did cars No. 123 and No. 124 run?

1876 A. They were on the rear of my train from Springfield to Boston; they were both rear cars. One was the rear car on the way-train and one was the rear car on the express-train from Boston to Worcester.

Int. 23. If I understand you, then, No. 123 ran in the rear of the train one way, and No. 124 ran in the rear of the train the other way?

A. Yes, sir. No. 124 ran in the rear going east and No. 123 came back from Worcester to Springfield in the rear coming up.

Int. 24. And they were always coupled together, except, as already stated, on the other end of the road?

A. Yes, sir; every day.

Int. 25. What did you understand at the time was the object of your keeping count of the stops made by your train while cars No. 123 and No. 124 were run in it?

A. Well, they were testing the brakes, and to see if the shoes wore the same.

Int. 26. When the shoes were worn out under the brakes, what was done with cars No. 123 and No. 124? Did they continue in further use in your train, or were they taken out and put into some other train?

A. They were taken away, both of them, on the 29th of January.

Int. 27. Were you ever a brakeman on the Boston & Albany Railroad; and, if so, when and for how long?

A. I was brakeman about four years. It is 18 years ago since I commenced, the 17th of February.

Int. 28. Eighteen years since you commenced, first as brakeman and then as conductor?

A. Yes, sir; and I was baggage-master three years.

Int. 29. Did you at any time operate the brakes on cars No. 123 and No. 124?

A. I did; I tried them several times when they first commenced running.

Int. 30. To which brake did you give the preference?

A. I thought No. 124 worked the easiest; took hold the best and quickest.

1877 Int. 31. What reason, if any, have you for thinking that the old Springfield brake on No. 124 seemed to take hold best?

A. I thought it would slack up the train quicker.

Cross-examined by the complainant, Tho's Sayles:

Cr.-int. 1. Who were the brakemen on your train when cars No. 123 and No. 124 were used?

A. Charles Haradan broke on those two cars. I had two other men, but they did not use those brakes at all. He was the hind brakeman, and he used those two cars.

Cr.-int. 2. Did he brake them all the time during the time they were in your train?

A. No. Between Boston and Worcester one came up on another train. I don't know what that brakeman's name was. No. 123 came up to Worcester on the half-past one train.

Cr.-int. 3. Was he the only brakeman who ran on your train that used these brakes all the time they were in your train?

A. Yes, sir; they were always on the hind end, and he was the hind brakeman. Each man has two cars.

Cr.-int. 4. Did you know why these brakes were put on those two cars?

A. To try. That is what they told me, that they were trying the brakes.

Cr.-int. 5. Did you know why they wanted to try them?

A. No; I did not.

Cr.-int. 6. Did you know there was any suit pending?

A. Well, no. The brakeman was telling me one day that there was a lawsuit about them. He told me a man was putting them on; that there was a lawsuit about them.

Cr.-int. 7. Was there any other car used in your train except those two?

A. Yes, sir. I have five cars going east, and four coming up nights; sometimes more. That is the usual train.

Cr.-int. 8. What kind of brakes did those other cars have?

A. They have the Hodge brakes—the Hodge patent.

Cr.-int. 9. You say you think the brake on No. 124 worked better than the one on No. 123?

1878 A. Yes, sir. No. 123, I think, was more stiff. It did not seem to go on so well.

Cr.-int. 10. Did the brake on No. 124 work better than the brakes on the other cars, the Hodge brake?

A. No; it did not.

Cr.-int. 11. It worked well, didn't it?

A. Well, I shouldn't as lief work it. I think it works harder; that is, I think it takes more strength to set it up tight.

Cr.-int. 12. Couldn't you stop the train as well with it?

A. I presume you could set it tight. I presume the wheels might be slid with it. That is all a brake can do.

Cr.-int. 13. You have often operated the Hodge brakes, I presume?

A. Yes, sir. They are in pretty general use on this road. They work very easy, the Hodge brakes do.

Cr.-int. 14. Did you try those brakes on car No. 123 and No. 124 often?

A. Well, no; not very often. When they first came on, sometimes I would take hold and set them up.

Cr.-int. 15. Were the brakes on No. 123 and No. 124, when they were together in the train, both applied at every station?

A. O, yes.

Cr.-int. 16. Where is this Charles Haradan?

A. He is running from Springfield to Albany now, on J. B. Adams's train.

Redirect:

Int. 32. Please state whether the train in which these cars run was stopped on curves; or, in other words, whether there are any stations located on curves on the road in your run.

A. Yes, sir; several; Wilbraham, Brookfield, and Rochdale.

Int. 33. Please state if you have observed any difference in the holding of the brake when the train was stopped at the stations located on curves.

A. If the brake is set when the car is on a straight line, and then it strikes a curve, it tightens it.

1879 Int. 34. Does the same thing apply to both these brakes?

A. Yes, sir; to any brake. If it is set on a straight line, and then you strike a curve, the tendency is to tighten it.

Int. 35. And that applies equally to one brake as another?

A. Yes, sir; it would have a tendency to tighten the brake, so that the car would stop quicker.

Int. 36. When the brakes are set on a straight track and the cars then run on to a curve, it has a tendency to tighten any brake?

A. Yes, sir.

Int. 37. The Hodge brake as well as any brake?

A. O, yes, sir; any brake. When it strikes a curve it would spring the trucks and draw it tighter.

Int. 38. Please state if you have observed whether the chains in "Defendants' Exhibit, old Springfield brake No. 124," overlap each other in other in setting up the brake.

A. I never knew that they did.

Int. 39. Have you any reason to believe that the chains did overlap? [Plaintiff objected.] Of course you did not get down under a car when it was running to look at the brake; it is not expected that a man would do that; it is very dangerous business.

A. I never heard any complaint about it in any way.

Int. 40. Would a brake, in your judgment, be an effective brake upon both trucks, provided the chains did overlap each other?

A. I should not think you could set them if they were lapped.

Int. 41. Should you deem it safe to run a train, all the cars of which were equipped with the old Springfield brake?

A. I should think it would be safe, certainly.

Recross:

Cr.-int. 17. You never saw the brakes when they were applied, did you?

A. No, sir.

Cr.-int. 18. Supposing a brake on a car should be applid on a
1880 straight track, and the brake set with the ratchet, and then that
running the car on a curve would tighten the brakes on one truck, so as to make the wheels slide, and loosen them on the other truck of the same car, would that be a safe brake, in your judgment, to run on a train of cars?

A. You could not tighten the brake.

Cr.-int. 19. That is not the question. I ask you to suppose the case. I have not said there is any such brake in existence.

A. You couldn't tighten it on one truck and have that loosen the other. It could not work so.

Cr.-int. 20. Supposing it will do that, would it be a safe brake?

A. If it slid the wheels it would be a good brake.

Cr.-int. 21. You say it could not be done, and if it slides the wheels it is a good brake. Now, sir, supposing the brake is applied on a straight track, as I first stated, hard enough to stop a car, ordinarily, at the station, but not to slide the wheels, and that the brake is set with the ratchet, and the car runs from there on to a curve, and, by running on to the curve, the brakes are tightened on one truck so as to slide the wheels, and the brake is loosened on the other truck,—supposing the brake would do that, would it be a safe brake to put on a train of cars?

A. Yes, sir. If it would slide the wheels, it would be a good protection enough.

Cr.-int. 21. If it slid the wheels on one truck, and loosened them on the other, would it be a good brake?

A. It would not do that.

Cr.-int. 22. I say, if it does that?

A. I see nothing the matter with the brake, if it will slide the wheels.

Cr.-int. 23. If the principle of the brake is such that it will slide the wheels on one truck by going on a curve, and loosen the wheels on the other truck, would that be a safe brake?

A. Yes, sir. If one set of wheels was sliding, and the other was loose, it would stop the train. They won't slide a great ways.

Cr.-int. 24. You think a brake of that kind would be a safe brake?

1881 A. Yes, sir.

Cr.-int. 25. You say, if the wheels slide, it is a good brake?

A. Yes, sir. That is all a brake can do. Set it tight enough to slide the wheels; that is doing all a brake can do, and more than it ought to do.

Cr.-int. 26. Will a brake stop a car quicker by sliding the wheels, than it will when it is applied so as to bring the wheels almost to the sliding point, without sliding them?

A. When it is almost at the sliding point, it holds better than it will at almost any other point. I don't think a car will stop so quick when the wheels are sliding.

Cr.-int. 27. Then you think it would be a good brake, if it slid one set of wheels in going on a curve, and loosened the set on the other truck, do you?

A. Yes, sir. The car would not go a great ways if the brake held it that much.

Redirect:

Int. 42. In running car No. 124, in your train, did you observe any tightening of one truck, and slacking of the other, on a curve?

A. No, sir. I never observed any such thing.

Int. 43. Do you think any such thing occurred on any curve over which you run with that car while it was in your train?

A. No; I don't think it could. I don't see how it could, any way, when connected through from one truck to the other.

Recross:

Cr.-int. 28. Did you ever get under a car, so that you could look at the brakes when applied on a curve?

A. No; I don't know that I ever have. That is not a very good position to see.

Redirect:

Int. 44. Had the circumstances alluded to in the previous interrogatories by complainant, happened on car No. 124, when running 1882 from a straight track to a curve, to wit, tightening up one truck, and loosening the other, so that one would hold but little, while the other held much, would you have been likely to discover a difference in holding the car?

A. No; I don't know that I should.

JOHN W. CLARK.

Deposition of Benjamin Ray.

Int. 1. What is your name, age, residence, and occupation?

A. Benjamin Ray; age, 39; car inspector of the Boston and Albany Railroad.

Int. 2. How long have you occupied the position of car inspector on the Boston and Albany road, at Boston?

A. Since 1850—22 years; 5 years on freight, and the balance on passenger-cars.

Int. 3. Does looking after the brakes, and adjusting and repairing the same, come particularly under your charge as inspector of cars?

A. A part of them, not the whole on the road. All that stay at the Boston and Albany depot in Boston, I do.

Int. 4. What kind of brakes did you find on car No. 123 and car

No. 124, of the Boston and Albany road, when they first came under your observation?

A. The Tanner brake was on No. 123, and this old Springfield brake on No. 124.

Int. 5. You will please look at "Defendants' Exhibit, large Tanner brake, No. 123," and state whether it correctly represents the application of that brake to car No. 123, as you saw it when it first came to Boston.

A. Yes, sir; I think it is the same.

Int. 6. What was the length of long and short arms of the truck-levers?

A. Twenty-seven inches, the long arm; the short arm, six.

Int. 7. What was the diameter of the windlass-wheel used at that time?

1883 A. A sixteen-inch wheel.

Int. 8. The iron on which the chain wound was how much?

A. An inch and a half.

Int. 9. Is that the common standard of windlass-wheel used on your road,—sixteen inches?

A. Yes, sir.

Int. 10. You will now please look at "Defendants' Exhibit, large Springfield brake," and state whether it correctly represents the brake as seen by you on car No. 124, when it came to Boston.

A. It does, sir.

Int. 11. Is the arrangement of levers the same on this as on that car?

A. It is, exactly.

Int. 12. The windlass-wheel and shaft are the same?

A. The same size.

Int. 13. About what time of year, or month in the year, were these brakes first noticed by you at Boston?

A. I think I noticed them about the 8th and 12th of December, 1871.

Int. 14. At that time were the cars new, or had they seen some service?

A. They were new.

Int. 15. What kind of wheels did you find on those cars?

A. Steel-tired wheels.

Int. 16. What was the weight of the brake-shoes used on them?

A. The separate heads weighed twenty-nine pounds.

Int. 17. And there were how many heads to a car?

A. Eight.

Int. 18. The whole weight, therefore, to each car was how many pounds?

A. Two hundred and thirty-two.

Int. 19. About what time did the cars, No. 123 and 124, with the aforesaid brakes on, commence running; and in whose train did they run?

A. They were put into M'r Clark's train, No. 124, Dec. 8th, 1871; No. 123, Dec. 12th, 1871.

1884 Int. 20. And how long did those cars continue to run in M'r Clark's train?

A. Until January 29th. No. 123, until January 18th. It wore out half a set of shoes between that time and the 30th of January.

Int. 21. Of which no account was made?

A. Yes, sir.

Int. 22. When the shoes were taken off from No. 123, did you weigh them and take note of the amount of iron consumed?

A. Yes, sir.

Int. 23. What did you find to be the consumption of iron?

A. Seventy-six pounds on No. 123.

Int. 24. Did you also weigh the iron on car No. 124, with the old Springfield brake; if so, what did you find to be the consumption of iron on that car?

A. Yes, sir; seventy-seven pounds—one pound difference.

Int. 25. Did you put a particular mark on the shoes of No. 123, so that you could identify them?

A. Yes, sir.

Int. 26. What was the mark?

A. A single cross, pricked on the face of the shoe with a cold chisel.

Int. 27. I had reference to those on the box.

A. Those were marked with two crosses; a tally, two straight marks, and then crossed with one.

Int. 28. What mark, if any, did you put on the shoes of No. 124, that were taken from M'r Clark's train?

A. I did not put any mark on them. Those are not marked. I put that mark on the shoes to identify them when I put them into the soda to take the grease off.

Int. 29. To distinguish the shoes of one car from the shoes of the other?

A. Yes, sir.

Int. 30. In further testing the efficiency of the Tanner brake on No. 123, and the old Springfield brake on No. 124, what further came to your knowledge in relation to brake-shoes for the same?

1885 A. I received two sets of shoes from M'r Adams to put on those two cars.

Int. 31. When those shoes came to you from M'r Adams did you note any particular mark on them; if so, what was that mark?

A. There was a cross on each shoe.

Int. 32. Will you please look at shoes marked "Defendants' Exhibit, brake-shoe 123," and then at "Defendant's Exhibit, brake-shoe 124," and state whether you find on them, as produced here, the same mark that you found on the ones sent to you in Boston, by M'r Adams?

A. Yes, sir; I have looked at them all round, and I find the mark on all of them.

Int. 33. Were you aware at that time that there was any other mark on them than the cross?

A. No, sir.

Int. 34. Is there any doubt in your mind as to whether the shoes here marked Exhibits 123 and 124 were worn out on the cars on which they purport to have been?

A. No, sir; I have no doubt at all.

Int. 35. Into whose train were these cars put after being taken from M'r Clark's train?

A. M'r Jennings'.

Int. 36. Is said train made up by yourself in Boston?

A. No, sir; made up by the yard man in Boston.

Int. 37. Are you informed as to the manner in which it is made up?

A. Yes, sir.

Int. 38. Please state how it is made up and where it runs to when it leaves Boston?

A. When it arrives in Boston there is a switching engine that takes one car at a time and shoves them in on the back track so as to get the mail car, baggage-car, and smoking-car ahead.

Int. 39. How many cars compose this train when made up?

A. Five.

Int. 40. Please name the cars.

A. There is a mail car, baggage-car, smoking-car, and two passenger-cars—No. 123 and No. 124.

1886 Int. 41. Do I understand that that is the regular train which M'r Jennings takes out from Boston every morning?

A. No, sir; every other morning.

Int. 42. What does he take on the alternate mornings?

A. He takes another train, similar to that.

Int. 43. What brakes are on that train?

A. Hodge brake.

Int. 44. To what point does this train run after leaving Boston?

A. It runs to Albany.

Int. 45. And when does it return?

A. It returns every other day—three times a week.

Int. 46. At what hour in the morning does that train leave Boston?

A. Five o'clock.

Int. 47. What instructions did you receive in regard to running No. 123 and No. 124 in said train, while the shoes here produced and marked with a cross were on said cars?

A. I was ordered to put the one that came in behind on one day at the head, so as to reverse the running of the two cars.

Int. 48. What was the object of changing No. 123 to the rear, and then No 124 to the rear every time they came to Boston?

A. As I understood it, it was to give the brake-shoes a fair test over the mountain.

Int. 49. And over the different grades on the Boston and Albany road running east and west?

A. Yes, sir.

Int. 50. Did you attend strictly, every other day, when the train came from Boston, to see that No. 123 was run in the rear, and then also No. 124?

A. Yes, sir.

Int. 51. Did you continue the alternation until the shoes were worn out?

A. Yes, sir.

Int. 52. The shoes having been worn out and removed from the cars in Boston, please state, if you know, the amount of iron consumed by this experiment on No. 123, and the amount of iron consumed on No. 124?

1887 A. On No. 123, there were 80 pounds consumed; on car No. 124, there were 81 pounds consumed.

Int. 53. Did you put a mark upon the shoes worn out upon each car by which you can identify them?

A. Yes, sir.

Int. 54. What mark did you put on the shoes of No. 123, and what mark did you put on the shoes of No. 124?

A. A single cross mark on the face of the shoes of No. 123; and a double cross—two crosses—on the face of the shoes of No. 124.

Int. 55. And do you identify the shoes as produced in connection with each exhibit as the ones which you took off from said cars and weighed the consumption of the metal thereof?

A. Yes, sir.

Int. 56. Did you attend personally to the weighing of the shoes before they were put upon the cars, and after they were removed?

A. Yes, sir.

Int. 57. What was the whole weight when they were put on?

A. Two hundred and thirty-two pounds.

Int. 58. How many days were the cars No. 123 and No. 124 run in M'r Jennings' train to consume the amount of iron stated by you in a previous answer?

A. Between forty-six and forty-eight days.

Int. 59. On what day did the experiment conclude on Jennings' train?

A. March 27th, on No. 124; March 25th, on No. 123.

Int. 60. Why two days' difference in concluding the experiment?

A. M'r Adams hauled the car off for some purpose; I think, to raise it.

Int. 61. And to make the experiment equal, it was run two more days before the shoes were taken off and weighed, is that it?

A. Yes, sir; that was the order.

Int. 62. After this second experiment of weighing the shoes was over, what was done with the brake of No. 123?

A. It was changed into the old Springfield brake.

1888 Int. 63. What parts of the Tanner brake were used in the change, and what discarded?

A. We discarded the equalizer or centre-lever and retained the rest of the work. You can use it all, I take it.

Int. 64. The truck-levers were the same as represented in the exhibit?

A. Yes, sir.

Int. 65. What was added?

A. Two more truck-levers properly connected.

Int. 66. After this change to what extent was the old Springfield brake applied to the cars?

A. It was applied to the whole five—the whole train.

Int. 67. Please state, if you know, how many brake-shoes have been worn out since the whole train was equipped with the old Springfield brake.

A. We have taken off two sets, and have got the third set on. We are running the third set.

Int. 68. How many sets in all have been worn out on cars No. 123 and 124 since about the middle of December?

A. The fifth is running.

Int. 69. After the brake on No. 123 was changed to the old Springfield brake, how much iron did it consume before the shoes were taken off?

A. It consumed eighty-two pounds.

Int. 70. In your judgment, were all the conditions the same, or nearly so, under which "Defendants' Exhibit, large Tanner brake, 123," and "Defendants' Exhibit, large Springfield brake, 124," were tried?

A. Yes, sir.

Int. 71. What complaints, if any, have you heard from brakemen, engineers, or conductors, or from any source, with regard to the operation of the train to which the old Springfield brake was applied?

A. I have not heard any from any engineer or conductor.

Int. 72. What, if any, from brakemen?

A. Sometimes they would speak of their not working very well; the slack wanted taking up, as they do always on any train.

Int. 73. On such complaint did you take up the slack or wear?

1889 A. Yes, sir.

Int. 74. And thereafter did the complaint cease or continue?

A. It ceased.]

Int. 75. With regard to the Hodge brake, which you say is used o the train running on alternate days, do complaints come to you of tha brake as not working effectually sometimes?

A. Yes, sir; of all brakes.

Int. 76. Whether or not there has been any complaint about th chains overlapping each other in the operation of the old Springfiel brake?

A. I don't remember ever having a complaint of that kind.

Int. 77. Can they overlap each other?

A. Not when they are adjusted properly.

Int. 78. Is it your business to keep not only the old Springfield brakes but all other brakes adjusted properly?

A. Yes, sir.

Int. 79. When the old Springfield brake is properly adjusted, or the Tanner brake, do you consider them efficient brakes?

A. Why, yes, I do.

Int. 80. Whether or not any complaint has come to you about either of those brakes not holding on a curve or straight tracks, or when the train was running from a curve to a straight track, or from a straight track to a curve?

A. No, sir.

Int. 81. In your judgment, would there be any difference in any of those brakes named the Hodge, Tanner, or Springfield brake in not holding on a curve, or not holding under the circumstances named in the previous question?

A. No, sir; I do not see why they would not hold as well on a curve as on a straight track.

Cross-examined by complainant, Tho's Sayles:

Cr.-int. 1. How long do shoes usually last on the passenger cars on your road?

1890 A. That depends wholly on the trains they run on. Special trains will wear out shoes very fast. Sometimes you will have to renew them once a fortnight on some of those special trains.

Cr.-int. 2. How long do the shoes last on the train that runs on opposite days to this train you are speaking of in which Nos. 123 and 124 are?

A. I should judge we shoe one as often as we do the other; only probably we do not put them all on at one time.

Cr.-int. 3. That is, you mean that the shoes on the Hodge brake last as long as they do on the Springfield and Tanner brake under the same circumstances?

A. Yes, sir; I have not noticed any difference.

Cr.-int. 4. About what, as a general thing, is the average length of time that shoes run?

A. I don't think, to average them, they would average over a month. I mean on special trains and other trains too they will average about a month.

Cr.-int. 5. How long do they last on the train that runs the same as this does; that is, the train that runs on alternate days, with the Hodge brakes on?

A. I never kept any account of them on any other train but this.

Redirect:

Int. 82. Therefore you do not know, from your own knowledge, how long they do run?

A. I cannot tell exactly how long they do run; I might average it.

Recross:

Cr.-int. 6. You stated that you changed the cars No. 123 and No. 124, or got orders to change them, so as to run one out one way in the rear, and the other in the rear going the other way. Is that the way they ran while they were in M'r Clark's train?

A. No, sir; not in M'r Clark's train.

Cr.-int. 7. Are you usually in the Boston depot when M'r Jennings' train arrives there?

A. I am usually there; and when I am not I have other men there.

1891 Cr.-int. 8. Were you there a week ago to-day when that train came in?

A. I can't state, sir.

Cr.-int. 9. You don't remember whether you were there or not?

A. I can't say; I might have been there and might not. I might have been doing something else.

Cr.-int. 10. Have the brakemen often complained to you when they came in there that those Springfield brakes did not hold good; that they could not stop the train with them, and would run by the stations?

A. I never heard but one man say so to my knowledge.

Cr.-int. 11. Who was that?

A. M'r Gardner.

Cr.-int. 12. When was that?

A. I can't give the date.

Cr.-int. 13. About how long ago?

A. I should judge about a week ago; might have been longer or shorter.

Cr.-int. 14. What part of the train does M'r Gardner run on?

A. The hind end.

Cr.-int. 15. Who is the next brakeman to him?

A. I don't know his name.

Cr.-int. 16. Isn't his name Bartlett?

A. I don't know, sir. I don't know the name of either of the others.

Cr.-int. 17. Did not the brakeman ahead of Gardner make a complaint about one of the cars not holding good, and say that it would run by the stations, at the same time M'r Gardner complained about it, and was not that a week ago to-day, at half past three in the afternoon?

A. I don't remember hearing anybody say anything but Gardner.

Cr.-int. 18. Gardner spoke in reference to cars No.'s 123 and 124 didn't he?

A. He spoke in reference to car No. 123.

Cr.-int. 19. What did he say about it?

1892 A. I can't recollect now what he said I am sure; but something about there being too much slack, or something of that kind. The chains too long is always what they harp on on all trains.

Cr.-int. 20. Did not M'r Gardner make use of these words, namely, pointing to car No. 123: "With these brakes I can't stop the train at all; and we have been running by the stations, and the conductor has been blowing us. This car and that"—pointing to 124—"ought to go into the shop to be fixed; it has been so for three weeks." Did not M'r Gardner make use of about those words?

A. He might have made use of part of them; but I don't think he did, to me, of part. I don't think he mentioned No. 124 car, and I was not aware that he spoke of the cars going into the shop either. I knew he said something about the brakes that day; but I couldn't give any dates.

Cr.-int. 21. Did you ever apply these brakes to the cars, ever work them on the cars?

A. We do, very often, when we repair them. If there is anything out of order, we put it on and try it, to see how it works.

Cr.-int. 22. But never on the road?

A. No, sir.

Cr.-int. 23. You merely apply it on the track where it stands?

A. Yes, sir.

Cr.-int. 24. Are these brakes applied on model 124 the same that they are on those two cars, No. 123 and No. 124?

A. Yes, sir. I should say they were.

Cr.-int. 25. Is the chain running from the windlass and shaft to the first lever, the upper chain or the lower one, in those cars?

A. It is the lower one, I think.

Cr.-int. 26. Is it so on this model, 124?

A. No, sir; I think not.

Redirect:

Int. 83. Would it, in your judgment, in any way affect the operation of the brake, whether the chain leading to the lever nearest the windlass was connected below or above the other chain?

1893 A. Not a particle, if you don't alter the length of your lever.

Int. 84. Is it or not a custom with brakemen to complain, more or less, of brakes of all kinds, in your experience as inspector and repairer of cars?

A. Yes, sir.

Recross:

Cr.-int. 27. Did you know a man by the name of Braman, who was brakeman on that train in which cars No. 123 and 124 were?

A. Yes, sir.

Cr.-int. 28. Did he ever complain to you about the Springfield brakes not working well?

A. Never, to my knowledge.

Redirect:

Int. 84 *a*. Although it is claimed by some that the Springfield brake and the Tanner brake hold a train, when well adjusted, as well, or nearly as well, as the Hodge brake, or the Stevens brake, why are these last-named brakes considered better than either the Springfield or Tanner brake?

A. Because it (the Hodge brake) is self-adjusting, for one thing. The brakeman can adjust it to suit himself. He can set it up partly on one end; and then go and set it up on the other, if the chain is too long. He can pass through the car and set it up on the other end, or jump off and run round.

Int. 85. This he cannot do on the Springfield brake or the Tanner brake?

A. No, sir.

Int. 86. This applies to both the Hodge and Stevens brake?

A. I don't know anything about the Stevens.

Recross:

Cr.-int. 29. With the Springfield brake, after winding it up at one end, so as to apply the brakes, cannot the brakeman go to the other end and apply the brakes harder?

A. I think likely he can.

Cr.-int. 30. Isn't it so with the Tanner brake?

A. Well, you may get some slack; yes, all that is left. Of course, if you don't wind it up, the chain bags down.

1894 Cr.-int. 31. Why, then, do you say that with the Hodge brake the brakeman can adjust it as he chooses—take up part of the chain at one end, and then go to the other end of the car, and take up the balance?

A. Because he can do it. I have done it myself. And there is a very good reason why. If you set the Hodge brake up on one end, it draws all the connections towards the brakeman tight-taut.

Redirect:

Int. 87. Supposing you perform the same operation on the Springfield brake, and the same on the Tanner brake, what will be the result upon the opposite windlass chains?

A. It will make them loose.

Int. 88. Both brakes are alike in that respect?

A. Yes, sir.

BENJAMIN RAY.

Deposition of John A. Smith.

Int. 1. What is your name, residence, age, and occupation?

A. John A. Smith. I am 39 years old; and locomotive-engineer on the Boston and Albany Railroad.

Int. 2. How long have you been such engineer on the Boston and Albany Railroad?

A. Well, since the consolidation of the Boston and Albany. I was employed, previous to that, on the Boston and Worcester Railroad. I have been running an engine about thirteen years.

Int. 3. When does the train that you haul out of Boston leave that place?

A. At five o'clock in the morning.

Int. 4. Who is conductor on that train?

A. M'r William Jennings.

Int. 5. What is the weight of the engine which you use to haul this train?

A. It is about 29 tons.

Int. 6. How much would you add to that for the tender, water, fuel, etc.?

1895 A. I should add about 15 tons.

Int. 7. And that would make, in all, how much?

A. 44 or 45 tons—engine and tender.

Int. 8. To what place do you haul this train?

A. Between Boston and Worcester.

Int. 9. What is the distance?

A. Forty-four miles and a fraction.

Int. 10. What is the average speed which you are obliged to make?

A. The average speed, I should say, would be from 25 to 30 miles an hour.

Int. 11. Do you run it as an express train or accommodation-train?

A. It is put down as an express train between Boston and Framingham, subject to being stopped by flags for passengers going to Palmer and west of Palmer.

Int. 12. You state that you are liable to be flagged at stations between Boston and Framingham. Framingham is about half way between Boston and Worcester, is it not?

A. Yes, sir.

Int. 13. This may take place at any station?

A. Yes, sir; any station and all stations.

Int. 14. What is the western terminus of this train which, you say, leaves Boston at five o'clock in the morning?

A. Albany.

Int. 15. When does that train return?

A. It is due in Boston at 3.30.

Int. 16. Then you have to take out two trains from Boston, one every other morning?

A. Yes, sir; one every other morning. One train goes west one day, and east the next.

Int. 17. In hauling these two trains, which leave Boston at five o'clock, of which William Jennings is conductor, have you or not discovered any difference in the stopping of the trains at the different stations between Boston and Worcester?

A. I have not.

Int. 18. What test do you frequently put the brakes to between Boston and Framingham?

1896 A. Well, when we are flagged up, I whistle for brakes, and the brakemen haul up.

Int. 19. When you are hauled up, have you discovered any difference in the time of hauling you up, one day with another?

A. No, sir, I have not. I usually have, where the sight is good, a particular place where I shut off steam and call for brakes.

Int. 20. Do you have the same sight at all times for calling for brakes?

A. The same sight at the same stations; that is, in clear weather. In foggy weather, perhaps the sight is not so good.

Int. 21. In foggy weather do you change the place of shutting off in calling for brakes?

A. In foggy weather I can't see the signals so quick, sometimes.

Int. 22. Have you been made aware, from any source, that different brakes were run on these two trains on different days?

A. I have.

Int. 23. When, and by whom?

A. I cannot fix the date exactly. It was some time last winter. I was at that time running the train down, and a gentleman came to me in Boston and made inquiries about the brakes—about the way they held.

Int. 24. What did you state to him in reference to the holding?

A. I cannot repeat the words exactly. I stated to him, when I was made aware of the difference, that I saw no difference in the holding of the trains.

Int. 25. How long did he state to you that you had been running the trains in that way, with different brakes on different trains on alternate days?

A. I should say he said a month or six weeks. I can't state positively as to that; but it is my impression that he said they had been on a month or six weeks.

Int. 26. Then I understand that you knew nothing about the
1897 change of brakes on the trains, by the stopping of the same, for five or six weeks, until your attention was called to it by this gentleman?

A. I knew nothing of it until my attention was called to it by this gentleman.

Int. 27. Do you recognize the complainant in this case, M'r Sayles, as the person who informed you of this change of brakes?

A. I should say he was the man.

Cross-examined by the complainant, M'r Sayles:

Cr.-int. 1. About what time last winter was it you saw M'r Sayles in Boston?

A. I can't fix the date, sir, exactly. My opinion would be it was along in March some time. I remember it was a cold and blustering day—or rather a cold day. I should think it was about that time; I can't testify positively; it might vary a few weeks one way or the other.

Cr.-int. 2. Is it a general rule, on your road, to whistle for brakes at stations?

A. No, sir; except in cases like the train that I run. The time card states that that will be stopped by signal from the station for passengers going to Palmer and west of Palmer.

Cr.-int. 3. How long have you run that train?

A. I think about nine years, with the exception of two or three weeks.

Cr.-int. 4. You have run it ever since these Springfield brakes have been on it?

A. Yes, sir; I have run it regularly some seven years. I suppose, of course, that includes the time.

Cr.-int. 5. What are the names of the brakemen who run on that train?

A. I think, at present, the name of the head brakeman is Stevens; and the hind man Gardner, I think. The middle man's name I don't know.

Cr.-int. 6. How long has the middle brakeman been there?

A. I can't tell that. He has been there a number of months; I can't tell how long; time passes off fast. He has been off a while and back again.

1898 Cr.-int. 7. How long have these other brakemen been on the train?

A. I can't tell the time. Stevens has been on for some time; I should say six months or more, perhaps eight or ten. Time passes off fast. I have no means of knowing exactly how long they have any of them been on.

Cr.-int. 8. About how long has the middle brakeman been on there?

A. I can't tell, sir, the time. He was on there, I should say, three or four months, perhaps more; and then was gone for a time, I should think one or two months, and then came back again. He has been back, I should think, two or three months.

Cr.-int. 9. How long has M'r Gardner been on?

A. I can't state positively, sir, the time. He has run the shortest of any of them, I should say.

Cr.-int. 10. Who was the hind brakeman before he came there?

A. I can't call his name. I knew him; I was acquainted with him by sight, and that was all.

Cr.-int. 11. Was he a small man?

A. No, sir; he was a large, stout man.

Cr.-int. 12. Do you know why he left the train?

A. I don't know, sir, why he did. I heard that there was some trouble about being trusteed; I don't know anything about it; it is mere hearsay. He had some trouble. It is nothing that I know much about; it is merely a story I heard. I think his name was Braman.

Cr.-int. 13. You do not see any difference in the stopping of a train, when the Springfield brakes are used on the cars and when the Hodge brake is used?

A. No, sir. As I have stated, the first intimation I had of it was when you spoke to me in Boston in regard to it. That was the first knowledge I had of the change, and since then I have seen no difference in the hauling up of the trains at all.

Cr.-int. 14. Some of your stops are made on curves?

A. Yes, sir; and pretty short curves some of them. There are one or two of them; one in particular is a short curve.

1899 Cr.-int. 15. The Springfield brake seems to work just as well on those curves as the Hodge brake, so far as stopping the cars is concerned?

A. I know no difference. I cannot tell whether I have the Springfield brake or the Hodge brake on; I know no difference in them.

Cr.-int. 16. You make no difference in shutting off the steam, whether you have one brake or the other?

A. None at all. It is something I don't know anything about, or pay any attention to. I don't know which train I have. When I call for brakes I do it at the proper place, where they have a chance to hold me.

Cr.-int. 17. Did you ever examine these brakes on the cars?

A. Not particularly. After my attention was called to it, I looked at the cars and saw how they were arranged. I saw that the Springfield brake was arranged with two chains. I have never examined them particularly.

Cr.-int. 18. Did anybody else ever talk to you about these brakes?

A. After you spoke to me about it, I said something to the conductor one day; that is about all. I think I have heard the baggage-master state that they were put on as a test; that is all. I have had very little conversation with any one about them.

Cr.-int. 19. Did you ever hear anybody on the train complain about the Springfield brake not holding very well?

A. No, sir.

Cr.-int. 20. You are well acquainted with the Hodge brake, I suppose; with the construction of it, I mean.

A. Not particularly. I know the general principle of it. It is something I have never had anything to do with. If I was held well, that was all I required or looked into.

Cr.-int. 21. Do you know anything about the Tanner brakes being on one of those cars?

A. No, sir.

Cr.-int. 22. Did you ever know a brake, such as is represented in the large model, called the Tanner brake, to be on the cars?

1900 A. No, sir; I never noticed or knew anything about it. It may have been on trains that I have run, but I never noticed it.

Redirect:

Int. 28. Please state whether or not some other engineer hauls these trains in from Worcester to Boston?

A. At present there is another man hauls it from Worcester to Boston. Last winter, for about four months, I hauled the train both ways.

Int. 29. Do you know who hauls these trains on alternate days from Springfield to Worcester?

A. It was M'r Hodgkins' train. He hauls it both ways. He brings it from Worcester to Springfield, and from Springfield to Worcester.

JOHN A. SMITH.

Deposition of Luther D. Hodgkins.

Int. 1. What is your name, age, residence, and occupation?

A. Luther D. Hodgkins; 34 years of age; residence, Worcester; occupation, locomotive engineer on the Boston and Albany Railroad.

Int. 2. How long have you been a locomotive engineer?

A. Since July, 1866.

Int. 3. Did you hear the deposition of M'r J. A. Smith?

A. I did, sir.

Int. 4. When he hauls the train named in his deposition, of which M'r William Jennings is conductor, into Worcester, and puts his engine on the side-track, who hooks on to his train to take it here?

A. I do, with my engine.

Int. 5. What is the weight of your engine?

A. It is about 32 tons.

Int. 6. What would you estimate the weight, including the tender, wood, and water?

A. About 47 tons.

1901 Int. 7. What is the speed at which you are required to run these trains, on alternate days, between Worcester and Springfield?

A. The average speed is from 25 to 30 miles an hour.

Int. 8. Are you liable to be flagged, or have you regular stations?

A. We have regular stations. We have only one flag station.

Int. 9. In calling for the brakes at this flag station, have you discovered any difference in the time in which the train is brought to rest, one day with another?

A. Well, I do not have to whistle for brakes but very seldom. At that station there is a board put up, which the brakemen can see as well as myself.

Int. 10. Whenever you do have occasion to stop, then, I will ask you if you have discovered any difference in the time, one day with another, in the stopping of the train?

A. I have not.

Int. 11. Are there any curves on the line of road over which you run upon which stations are located?

A. There are.

Int. 12. At what places?

A. At Warren there is a curve where the depot stands; and at Brimfield the flag station stands on a curve.

Int. 13. In hauling these trains here, day after day, and making stops at all the stations, have you or not discovered any difference in bringing the train to rest at the stations, one day with another?

A. I have not.

Int. 14. Had it ever come to your knowledge, before your attention was called to this matter, that you were hauling a train one day with one kind of brake, and another day with another and a different kind of brake?

A. Yes, sir.

Int. 15. Please state under what circumstances, and when?

A. Some time in the winter we stopped at West Brookfield, and I got off my engine to go back to the depot, and I noticed that the lever on
the forward brake-beam was outside, under the baggage car. I
1902 asked the baggage-master what kind of brake he had there. I
don't know the reply he made, really. I asked him how long the
brake had been on there; and he said they had been running about two weeks, and wanted to know if I had not noticed it before. I told him I had not.

Cross-examined by M'r Sayles:

Cr-int. 1. Did you run any passenger trains while they were using the old single brakes, before they put on the Hodge brake?

A. No, sir; I think not. I don't know for certain. I can't say.

LUTHER D. HODGKINS.

Deposition of Lewis A. Sherts.

Int. 1. Will you please state your name, age, residence, and occupation?

A. My name is Lewis A. Sherts; age, fifty-nine; residence, Springfield; occupation, locomotive engineer on the Boston and Albany Railroad.

Int. 2. How long have you been locomotive engineer on the Boston and Albany Railroad?

A. Twenty-seven years, the 1st of August.

Int. 3. Where, on this road, have you run trains?

A. Well, I have run all along between Worcester and here, and here and Pittsfield.

Int. 4. Where are you running now?

A. Between here and Pittsfield; and have been for the last fourteen years, pretty much all the time, with the exception of a few extra trips east.

Int. 5. What train do you run from here to Pittsfield?

A. The 9.10 train; the middle train.

Int. 6. Who is conductor on that train?

A. John B. Adams.

Int. 7. Who are the brakemen on that train?

A. A man by the name of Taylor is one. I don't know who the other is. We have been shifting them lately.

1903 Int. 8. Do you run the same train every day, or are there two different trains?

A. I run the same train up one day and down the next, making two different trains. The train I run up to-day goes down to-morrow; and the train that I take up to-morrow will go down the next day. We run a different train every day.

Int. 9. Please state if you have observed the fact as to whether there has been any difference in the time in which the brakemen bring your train to rest one day compared with another.

A. I have never noticed any difference in the stopping of either of the trains.

Int. 10. What are the grades on the line of the Boston and Albany road between this place and Pittsfield?

A. From here to Chester it will average about forty-five feet to the mile.

Int. 11. Are the grades heavy on the other side of the mountain?

A. There we have twelve miles on an eighty-three foot grade to go up from here, and six miles of grade to go down on the other side.

Int. 12. What is the weight of the engine by which you haul these trains?

A. Thirty tons.

• • • • • • • • •

Int. 14. What, making a rough estimate, would the tender and all add to the thirty-ton engine?

A. I have never weighed a tender to come at an estimate. The coal

would weigh three tons. I don't know what the water would weigh. Call it five tons.

Int. 15. In passing down on the western slope of the Green Mountains, towards Pittsfield, are almost all your stops made on down grades?

A. We stop at one station, Dalton, going on a down grade.

Int. 16. In running these trains on alternate days between Springfield and Pittsfield, and especially on the down grade at Dalton, have you at any time discovered any difference in the time of stopping the train?

1904 A. I have not.

Int. 17. Have you at any time, and if so, when and by whom, been made aware that the two trains are equipped with different brakes?

A. I am not aware that there are different brakes.

Int. 18. Then, do I understand, that it has never come to your knowledge that one train is equipped with one kind of brake and the other train with another kind?

A. No, sir; I was never notified of that.

Int. 19. It has never come to your knowledge from any source?

A. No, sir.

Cross-examined by M'r Sayles:

Cr.-int. 1. Does not your train sometimes run by the stations?

A. Sometimes it does.

Cr.-int. 2. You don't know what days it runs by most?

A. No.

Cr.-int. 3. You don't keep any account of it?

A. No, sir.

Cr.-int. 4. Do the trains often run by stations?

A. Not often.

Cr.-int. 5. Do they some days more than others?

A. No, I don't know as they do. Yes, sir; some days we will slip by one station a little ways, and the next station we will be stopped right up at it.

Cr.-int. 6. So that you can't tell whether one of these trains runs by more stations than the other?

A. I don't think they do.

Cr.-int. 7. You can't tell whether they do or not, if you keep no account of it, can you?

A. No.

Cr.-int. 8. You stated that they had changed brakemen lately on one of those trains?

A. Yes, sir; we have shifted one of our brakemen off.

Cr.-int. 9. Who was that?

A. Wood went off, and I don't know who took his place.

Cr.-int. 10. Did he run on this train that M'r Adams runs?

1905 A. He run on Adams' train.

Cr.-int. 11. What train is Wood on now?

A. He isn't on the road at present, that I know of.

Cr.-int. 12. How long have you run this train of M'r Adams'?

A. About sixteen or seventeen years.

Cr.-int. 13. You used to run trains, then, when they used the single brake?

A. Yes, sir.

Cr.-int. 14. Did you have any trouble in stopping at stations then?

A. No; the cars were shorter and easier handled than they are now.

Cross-examined by M'r Sayles:

Cr-int. 1. Did you run any passenger trains while they were using the old single brakes, before they put on the Hodge brake?

A. No, sir; I think not. I don't know for certain. I can't say.

LUTHER D. HODGKINS.

Deposition of Lewis A. Sherts.

Int. 1. Will you please state your name, age, residence, and occupation?

A. My name is Lewis A. Sherts; age, fifty-nine; residence, Springfield; occupation, locomotive engineer on the Boston and Albany Railroad.

Int. 2. How long have you been locomotive engineer on the Boston and Albany Railroad?

A. Twenty-seven years, the 1st of August.

Int. 3. Where, on this road, have you run trains?

A. Well, I have run all along between Worcester and here, and here and Pittsfield.

Int. 4. Where are you running now?

A. Between here and Pittsfield; and have been for the last fourteen years, pretty much all the time, with the exception of a few extra trips east.

Int. 5. What train do you run from here to Pittsfield?

A. The 9.10 train; the middle train.

Int. 6. Who is conductor on that train?

A. John B. Adams.

Int. 7. Who are the brakemen on that train?

A. A man by the name of Taylor is one. I don't know who the other is. We have been shifting them lately.

1903 Int. 8. Do you run the same train every day, or are there two different trains?

A. I run the same train up one day and down the next, making two different trains. The train I run up to-day goes down to-morrow; and the train that I take up to-morrow will go down the next day. We run a different train every day.

Int. 9. Please state if you have observed the fact as to whether there has been any difference in the time in which the brakemen bring your train to rest one day compared with another.

A. I have never noticed any difference in the stopping of either of the trains.

Int. 10. What are the grades on the line of the Boston and Albany road between this place and Pittsfield?

A. From here to Chester it will average about forty-five feet to the mile.

Int. 11. Are the grades heavy on the other side of the mountain?

A. There we have twelve miles on an eighty-three foot grade to go up from here, and six miles of grade to go down on the other side.

Int. 12. What is the weight of the engine by which you haul these trains?

A. Thirty tons.

• • • • • • • • • •

Int. 14. What, making a rough estimate, would the tender and all add to the thirty-ton engine?

A. I have never weighed a tender to come at an estimate. The coal

would weigh three tons. I don't know what the water would weigh. Call it five tons.

Int. 15. In passing down on the western slope of the Green Mountains, towards Pittsfield, are almost all your stops made on down grades?

A. We stop at one station, Dalton, going on a down grade.

Int. 16. In running these trains on alternate days between Springfield and Pittsfield, and especially on the down grade at Dalton, have you at any time discovered any difference in the time of stopping the train?

1904 A. I have not.

Int. 17. Have you at any time, and if so, when and by whom, been made aware that the two trains are equipped with different brakes?

A. I am not aware that there are different brakes.

Int. 18. Then, do I understand, that it has never come to your knowledge that one train is equipped with one kind of brake and the other train with another kind?

A. No, sir; I was never notified of that.

Int. 19. It has never come to your knowledge from any source?

A. No, sir.

Cross-examined by M'r Sayles:

Cr.-int. 1. Does not your train sometimes run by the stations?

A. Sometimes it does.

Cr.-int. 2. You don't know what days it runs by most?

A. No.

Cr.-int. 3. You don't keep any account of it?

A. No, sir.

Cr.-int. 4. Do the trains often run by stations?

A. Not often.

Cr.-int. 5. Do they some days more than others?

A. No, I don't know as they do. Yes, sir; some days we will slip by one station a little ways, and the next station we will be stopped right up at it.

Cr.-int. 6. So that you can't tell whether one of these trains runs by more stations than the other?

A. I don't think they do.

Cr.-int. 7. You can't tell whether they do or not, if you keep no account of it, can you?

A. No.

Cr.-int. 8. You stated that they had changed brakemen lately on one of those trains?

A. Yes, sir; we have shifted one of our brakemen off.

Cr.-int. 9. Who was that?

A. Wood went off, and I don't know who took his place.

Cr.-int. 10. Did he run on this train that M'r Adams runs?

1905 A. He run on Adams' train.

Cr.-int. 11. What train is Wood on now?

A. He isn't on the road at present, that I know of.

Cr.-int. 12. How long have you run this train of M'r Adams'?

A. About sixteen or seventeen years.

Cr.-int. 13. You used to run trains, then, when they used the single brake?

A. Yes, sir.

Cr.-int. 14. Did you have any trouble in stopping at stations then?

A. No; the cars were shorter and easier handled than they are now.

Cross-examined by M'r Sayles:

Cr-int. 1. Did you run any passenger trains while they were using the old single brakes, before they put on the Hodge brake?

A. No, sir; I think not. I don't know for certain. I can't say.

LUTHER D. HODGKINS.

Deposition of Lewis A. Sherts.

Int. 1. Will you please state your name, age, residence, and occupation?

A. My name is Lewis A. Sherts; age, fifty-nine; residence, Springfield; occupation, locomotive engineer on the Boston and Albany Railroad.

Int. 2. How long have you been locomotive engineer on the Boston and Albany Railroad?

A. Twenty-seven years, the 1st of August.

Int. 3. Where, on this road, have you run trains?

A. Well, I have run all along between Worcester and here, and here and Pittsfield.

Int. 4. Where are you running now?

A. Between here and Pittsfield; and have been for the last fourteen years, pretty much all the time, with the exception of a few extra trips east.

Int. 5. What train do you run from here to Pittsfield?

A. The 9.10 train; the middle train.

Int. 6. Who is conductor on that train?

A. John B. Adams.

Int. 7. Who are the brakemen on that train?

A. A man by the name of Taylor is one. I don't know who the other is. We have been shifting them lately.

1903 Int. 8. Do you run the same train every day, or are there two different trains?

A. I run the same train up one day and down the next, making two different trains. The train I run up to-day goes down to-morrow; and the train that I take up to-morrow will go down the next day. We run a different train every day.

Int. 9. Please state if you have observed the fact as to whether there has been any difference in the time in which the brakemen bring your train to rest one day compared with another.

A. I have never noticed any difference in the stopping of either of the trains.

Int. 10. What are the grades on the line of the Boston and Albany road between this place and Pittsfield?

A. From here to Chester it will average about forty-five feet to the mile.

Int. 11. Are the grades heavy on the other side of the mountain?

A. There we have twelve miles on an eighty-three foot grade to go up from here, and six miles of grade to go down on the other side.

Int. 12. What is the weight of the engine by which you haul these trains?

A. Thirty tons.

• • • • • • • • • •

Int. 14. What, making a rough estimate, would the tender and all add to the thirty-ton engine?

A. I have never weighed a tender to come at an estimate. The coal

would weigh three tons. I don't know what the water would weigh. Call it five tons.

Int. 15. In passing down on the western slope of the Green Mountains, towards Pittsfield, are almost all your stops made on down grades?

A. We stop at one station, Dalton, going on a down grade.

Int. 16. In running these trains on alternate days between Springfield and Pittsfield, and especially on the down grade at Dalton, have you at any time discovered any difference in the time of stopping the train?

1904 A. I have not.

Int. 17. Have you at any time, and if so, when and by whom, been made aware that the two trains are equipped with different brakes?

A. I am not aware that there are different brakes.

Int. 18. Then, do I understand, that it has never come to your knowledge that one train is equipped with one kind of brake and the other train with another kind?

A. No, sir; I was never notified of that.

Int. 19. It has never come to your knowledge from any source?

A. No, sir.

Cross-examined by M'r Sayles:

Cr.-int. 1. Does not your train sometimes run by the stations?

A. Sometimes it does.

Cr.-int. 2. You don't know what days it runs by most?

A. No.

Cr.-int. 3. You don't keep any account of it?

A. No, sir.

Cr.-int. 4. Do the trains often run by stations?

A. Not often.

Cr.-int. 5. Do they some days more than others?

A. No, I don't know as they do. Yes, sir; some days we will slip by one station a little ways, and the next station we will be stopped right up at it.

Cr.-int. 6. So that you can't tell whether one of these trains runs by more stations than the other?

A. I don't think they do.

Cr.-int. 7. You can't tell whether they do or not, if you keep no account of it, can you?

A. No.

Cr.-int. 8. You stated that they had changed brakemen lately on one of those trains?

A. Yes, sir; we have shifted one of our brakemen off.

Cr.-int. 9. Who was that?

A. Wood went off, and I don't know who took his place.

Cr.-int. 10. Did he run on this train that M'r Adams runs?

1905 A. He run on Adams' train.

Cr.-int. 11. What train is Wood on now?

A. He isn't on the road at present, that I know of.

Cr.-int. 12. How long have you run this train of M'r Adams'?

A. About sixteen or seventeen years.

Cr.-int. 13. You used to run trains, then, when they used the single brake?

A. Yes, sir.

Cr.-int. 14. Did you have any trouble in stopping at stations then?

A. No; the cars were shorter and easier handled than they are now.

Cr.-int. 15. You stopped just as regularly then as you do now?

A. Yes, sir. There wasn't more than half the heft to a train then that we have now.

Cr.-int. 16. How long ago was that?

A. That was when I first commenced to run, sixteen or seventeen years ago.

Cr.-int. 17. How long is it since they put the double brakes on the road between here and Albany?

A. I can't tell how long it is.

Cr.-int. 18. How long is it since they began to put on these heavier cars?

A. They have been increasing them every year; making them larger and heavier.

Cr.-int. 19. Has there been any other brakeman on M'r Adams' train since last January, who has left?

A. I guess this Wood was on at that time. He was on until a month or so ago. I think he is in Worcester. I heard he was there driving a hack. I don't know certain whether he is or not.

Cr.-int. 20. Is he the only one who has left the train?

A. He is the only one who has left, I guess, since January.

Cr.-int. 21. What is Wood's first name?

A. I can't tell you. I can't tell Taylor's given name. I never heard it mentioned, as I know of.

1906 Cr.-int. 22. Couldn't they hold these trains at the stations now with the single brake?

A. It would be pretty difficult to do it. They could not do it without putting on more brakemen. They would have to have a brakeman between every two cars to do it with single brakes now. The speed is greater now than it used to be. We used to be three hours going between here and Pittsfield, and now we are two hours and seventeen minutes.

Cr.-int. 23. You think it would not be safe, then, to run passenger trains, as they run them now, with single brakes?

A. No, sir; not at the speed we run them now, on those heavy grades.

Redirect:

Int. 20. That is, not unless the number of brakemen was increased?

(Plaintiff objected to the question as leading.)

A. Yes, sir; you must increase the number of brakemen.

LEWIS A. SHERTS.

Deposition of Joseph Brown.

Int. 1. Please state your name, age, residence, and occupation.

A. My name is Joseph Brown; residence, Greenbush, N. Y.; age, 46; occupation, locomotive engineer.

Int. 2. How long have you been a locomotive engineer?

A. About fifteen years.

Int. 3. Have you heard the depositions of M'r Smith and M'r Hodgkins?

A. I have.

Int. 4. You will please state if you hook on to the train which leaves Boston for Albany, which is taken from Boston to Worcester by M'r Smith, from Worcester to Springfield by M'r Hodgkins, from here to Pittsfield by M'r Sherts, at Pittsfield.

1907 A. Yes, sir.

Int. 5. To what place do you take it?

A. Albany.

Int. 6. What is the weight of your engine, including the tender, by which you haul that train?

A. I believe the engine is about twenty-eight tons.

Int. 7. How much would you add to that for tender, fuel, water, &c.?

A. About twelve tons, I should think.

Int. 8. Making in all how much?

A. About forty tons.

Int. 9. In hauling this train on alternate days, please state if you have noticed any difference in the time in which the brakemen bring the train to rest at the different stations.

A. I have not. I was not aware that they had any different brakes.

Int. 10. Who is conductor on that train?

A. M'r John B. Adams.

Int. 11. Please state, if you know, who are the brakemen now employed on that train.

A. I know only the name of one, M'r Taylor. I don't know what his first name is.

Int. 12. Do you haul these trains from Albany to Pittsfield?

A. No, sir; not that train.

Int. 13. Who does?

A. I think M'r Teeling. I am not positive about that, but that is my impression.

Cross-examined by M'r Sayles:

Cr.-int. 1. How long have they used double braks on that train?

A. I don't know.

Cr. int. 2. You have run that train, you say, for how many years?

A. I have run it only since the fifth of this month. I have been running freight.

Cr.-int. 3. You never run a passenger train before?

A. Not as a regular thing. I have frequently, at all times, run a trip or more; a week, sometimes, more or less.

1908 Cr.-int. 4. At what time?

A. At different times. In case a passenger engineer was sick, or something, I have sometimes been put on to run their trains, more or less.

Cr.-int. 5. Did you ever run a passenger train that had on it single brakes?

A. I have not paid any attention to the brakes, any way—whether they were single or double, or what they were; therefore I cannot say about that.

Cr.-int. 6. Are some of the stations, where you have run these trains, on curves?

A. Some of them are.

Cr.-int. 7. You do not see any difference in the stopping of the trains on the two different days?

A. I have not been able to discover any, or taken any notice. They all apparently made the stops, as a general thing, alike.

Cr.-int. 8. You shut off steam at the same place on both trains?

A. About the same, according to the speed the train would be under. That made a little difference about shutting off.

JOSEPH BROWN.

Deposition of Cornelius Teeling.

Int. 1. What is your name, age, residence, and occupation?

A. Cornelius Teeling; age, about forty years; residence, Greenbush, N. Y.; occupation, locomotive engineer.

Int. 2. How long have you been so employed?

A. In the neighborhood of 18 or 20 years.

Int. 3. On what road?

A. The Boston and Albany.

Int. 4. Formerly known as the Western road, before the consolidation with the Boston and Worcester?

A. Yes, sir.

Int. 5. Have you heard the evidence of M'r Smith, M'r Hodgkins and M'r Brown?

1909 Yes, sir; pretty much all of it.

Int. 6. Are you acquainted with the time of starting certain trains from Boston, known as the five o'clock train, of which M'r William Jennings is conductor?

A. I am not much posted on the times of leaving Boston and Springfield.

Int. 7. What time do these trains leave Albany to come east?

A. I leave Albany at 6.30, our time—Boston time—and 6.40 from Greenbush.

Int. 8. Are the trains you haul, those taken up by M'r Adams the day before?

A. I think they are. I am not positive.

Int. 9. Who is conductor on the trains which you haul from Albany?

A. Charles Marsh.

Int. 10. Who is the rear brakeman?

A. The head brakeman is M'r Prouty. Charles Chambeau has been acting as middle brakeman; there is a new man on now. I can't tell his name.

Int. 11. Who is the rear brakeman?

A. James Lyon.

Int. 12. What is the weight of the engine with which you haul these trains every other day?

A. From 26 to 28 tons.

Int. 13. What would you add for tender?

A. I should think somewhere betwixt 30 and 32 tons. That includes the whole. Probably it will go a little more. The engine is not very heavy. It is a pretty light engine. It is one of the old class of Mason engines.

Int. 14. Are the cars which make up the trains that leave Albany on alternate days the same or different?

A. I can't say exactly what the numbers of the cars are that we haul every day.

Int. 15. But the numbers would be different? They would not be the same cars?

A. No, sir; I think not.

Int. 16. What is the time between Albany and Pittsfield?

A. The time would be about 25 or 30 miles an hour.

1910 Int. 17. Are any of the stations at which you stop located on curves?

A. Some of them are.

Int. 18. In hauling these two trains on different days, have you or not discovered any difference in stopping?

A. No, sir; I have not, particularly. I don't know that I have discovered any difference. They all make very good stops.

Int. 19. Has or not your attention at any time been called to the fact that there were different brakes on the two trains hauled on alternate days?

A. Only one morning, at Chatham, as I came out from breakfast, I was walking up from the depot to the engine, and the head brakeman spoke to me and said, "You haven't seen this, have you?" Said I, "What is it?" He said, "Well, we have got a double chain on here." I just cast my eye between the tender and baggage-car, and I saw two chains there. That is all I ever knew about it.

Int. 20. How long ago was that?

A. Probably it was a month or six weeks ago.

Int. 21. With the exception of what you have already stated, I understand you were not aware that there were two different kinds of brakes on the two different trains?

A. Not that I know of. I don't recollect.

Int. 22. Please state whether you know what brakes will be on the train that you will probably haul to-morrow morning, at half-past six.

A. No, sir; I do not.

Int. 23. You don't take into account what brakes are used on a particular day?

A. No, sir; no particular notice. I don't look after the brakes much of any.

Int. 24. If there were an inefficient brake put on your train, would you be likely to discover its inefficiency, in bringing the train to rest at the stations?

A. All the way I could tell, if it don't stop, I should ask what the matter was; and they would probably say it was a very poor brake, or something of that sort.

1911 Int. 25. Have any complaints of that kind come to your knowledge?

A. Not very lately, sir.

Cross-examined by M'r Sayles:

Cross-int. 1. You say "not very lately." How lately?

A. I can't exactly tell how long it would be. I can't form any idea exactly when it was.

Cross-int. 2. A month ago, or two months, or a week?

A. I should think it would be longer than that, sir.

Cross-int. 3. You have heard no complaints for the last two months?

A. Not that I know of. I have not heard any complaint that I know of for the last two months. The men have broke me since I run that train very well indeed. I have no fault to find whatever.

Cross-int. 4. How long have you run that train?

A. I think since some time along in December. I can't say exactly how long I have run this train.

Cross-int. 5. There have been no complaints since you run that train?

A. No, sir; the men have broke me up, and broke me up very good indeed. They have stopped me at the stations very well indeed. There have been no complaints whatever, that I know of.

Cross int. 6. How long have you run passenger trains on the road?

A. Well, quite a number of years.

Cross-int. 7. How many?

A. Well, I can't say the number of years I have run them, exactly.

Cross-int. 8. You were running passenger trains while they were using the old single brake?

A. I wouldn't swear positively whether I was or not.

Cross-int. 9. Did you run passenger trains there before 1856?

A. I think not. I think I was running freight in 1856.

Cross-int. 10. About how soon after that did you ever run a passenger train?

1912 A. I don't know, exactly. The first time that I ever took a passenger train steady was the time that the owl train was first put upon the road here.

Cross-int. 11. What year was that?

A. That I can't say exactly.

Cross-int. 12. Did you use to run passenger trains occasionally before?

A. Once in awhile—extra like. I would go on to a passenger train once in awhile.

Cross-int. 13. I mean, before 1856?

A. I can't say whether I did or not before 1856.

Cross-int. 14. What train does this M'r Chambeau run on now?

A. He is in the yard now, a baggage-man on the Albany side.

Cr.-int. 15. How long since he left the train?

A. I should think it was some day last week. Only a short time ago.

Cr.-int. 16. Have the other brakemen been on the train ever since last December?

A. About ever since we run the train. M'r Prouty, when I took the train, was off for a few weeks; but came on again, and has been on the train ever since, except, may be, a day or two.

Cr.-int. 17. Did you see that Tanner brake on the car, when it was on?

A. I don't remember whether I saw that brake or not. I saw something similar to it. I don't know whether that is the kind of brake or not.

Cr.-int. 18. You don't know whether it was that brake called the Tanner brake, that was on the car that was shown to you, or the Springfield brake?

A. I don't know whether it was the Tanner brake, or the Hodge brake, or what brake it was.

Cr.-int. 19. I mean the one to which your attention was called at Chatham?

A. At Chatham, I looked betwixt the tender and baggage-car, and I saw two chains that were fastened to the end of the staff. That 1913 is as far as I looked at it. I did not go back any further. In fact, I didn't pay much attention to it; just merely cast my eye, walked on, got on the engine, and started off.

CORNELIUS TEELING.

Deposition of R. C. Steele.

Int. 1. What is your name, age, residence, and occupation?

A. My name is R. C. Steele; I am 47 years old; reside on Greenwood street, Springfield, Mass., and run a locomotive engine on the Boston & Albany Railroad, between here and Pittsfield.

Int. 2. How long have you run a locomotive on the Boston and Albany Railroad?

A. It is about 20 years. Somewhere in that vicinity. I can't tell exactly.

Int. 3. What can you say in relation to the grades over which you have to haul your train from Springfield to Pittsfield and return?

A. Well, the grades are pretty heavy, part of the way. I can't tell how heavy. After we leave Chester they are very heavy. They are the heaviest grades we have on the road.

Int. 4. What train is it your duty to haul from Pittsfield to Springfield?

A. I come down on Marsh's train, that gets in here at 11.15.

Int. 5. What time does that train leave Boston to go to Albany?

A. I can't tell you what time it would leave there.

Int. 6. What time does that train get here, coming back from Boston?

A. I bring it in from Pittsfield; but what time the cars get in, I don't know. I don't know what train they come back on.

Int. 7. When does the train leave Albany that you haul?

A. I have not looked on the card to see. Somewhere about five o'clock.

Int. 8. What time does it get into Pittsfield?

1914 A. It is due in Pittsfield at 8.52.

Int. 9. Then you take the train in charge?

A. I take the train over here.

Int. 10. Who is conductor on the train?

A. Charles Marsh.

Int. 11. Who is brakeman?

A. The rear-end man is James Lyon; Charles Chambeau is the middle man; the name of the man at the forward end is Prouty.

Int. 12. In hauling your train from Pittsfield to Springfield, do you have to cross the Green Mountain range?

A. Yes, sir.

Int 13. That is, you go up on the western slope of it, and come down on the eastern slope to this place?

A. Yes, sir.

Int. 14. In hauling that train from Pittsfield across those mountains, have you discovered, during the last two or more months, any difference in the time of stopping the train at the stations, from day to day?

A. No; I don't know as I have. There is no more difference than there is every day. I find, in stopping at the different stations, they let me by, or won't let me up to the station; but I don't notice any difference from day to day.

Int. 15. Are they as likely to stop you short as to run by?

A. Yes, sir; just as likely.

Int. 16. But, as a general rule, they try to stop at the stations?

A. Yes, sir. As a general rule, they come up to the stations well. These men are not as good men as you might have, because they don't work together. I don't think there is any fault with the brakes on the cars.

Int. 17. Then, as I understand you, you have not discovered any difference in the stopping of the trains, comparing one day with another?

A. No, sir. I have been told, since I came here to-day, that they are running two kinds of brakes there; but I did not know it before.

1915 Cross-examined by Mr Sayles:

Cr.-int. 1. How long have you run this train?

A. About two years.

Cr.-int. 2. How did you learn that there was a different kind of brake on the train?

A. Well, our rear-end man, Jim Lyon, was telling me out here in the depot, since we came in here, that we have been running two different kinds of brakes on the train, one day one kind, and the next another. That was the first I knew of it.

Cr.-int. 3. Has this M'r Marsh run as conductor on the train that you haul, for a long time?

A. I should think he had been there five or six years, if not more. He has been on there a long while. I can't tell exactly how long.

Cr.-int. 4. Have you ever heard any complaint about the brakes not holding good?

A. I have not; never heard a word said.

Cr.-int. 5. You say the cars often run by the stations?

A. Yes, sir. They would just as soon run by where the train has been running without steam four or five miles, on a down grade, as where it had been running with steam up to the station. I consider it is the fault of the brakemen, in not putting the brakes on. That is the reason why they run by.

Cr.-int. 6. Have they not run by more within the last four or five months than before?

A. I have not noticed any difference, at least. Sometimes I have to whistle for them. I can tell by the speed they are running, when they get near a station, whether they are going to run by or not; and if I think they are going to run by, I whistle for brakes. I think it is more the fault of Jim Lyon than anything else that the train runs by. He has been brakeman on that train for sixteen or seventeen years, and I think he has been a little careless. If I were conductor on the train, I would not have him there more than half an hour. I suppose he has been there so long he thinks he is a fixture there, and it don't make any difference whether he brakes or not.

1916 Cr.-int. 7. Have you ever found fault with him for not braking?

A. Not anything particular. Sometimes I blow him a little when we get into the refreshment room at Chester. He has been there so long, it don't do much good to say anything to him. I have heard the other men on the train say that M'r Marsh had to push him out on the platform, sometimes, to put on his brake.

Cr.-int. 8. M'r Marsh has run this train all the time you have been running on it?

A. Yes, sir; it has been his train. He has been away on a vacation for a week or two, it may be, once or twice.

Cr.-int. 9. Who would run his train while he was on a vacation?

A. Stephen Chapin run his train while he was off, the only time he has been off for any length of time since I have been running the train. I don't recollect anybody else running the train but Chapin and Marsh.

Cr.-int. 10. How many cars are there in this train?

A. We get from five to six. Some days we have six. The usual number is five.

R. C. STEELE.

Deposition of William Jennings.

Int. 1. What is your name, age, residence, and occupation?

A. William Jennings; I was 54 years old the 19th of July; residence, Boston; occupation, conductor on the Boston and Albany Railroad.

Int. 2. How long have you been a conductor on the Boston and Albany Railroad?

A. I guess 26 or 28 years, and I don't know but more.

Int. 3. How were you employed on that road previous to your becoming a conductor?

A. I commenced on the 14th day of May, 1840, as baggage-man, running from here to Boston and back. M'r Parker was the conductor

1917 Int. 4. When did you begin to run as baggage-man from Springfield to Albany ?

A. I think it was something like two years after that before I commenced running through from Boston.

Int. 5. What kind of cars were used in your train for baggage-cars ?

A. Common house cars.

Int. 6. What other name was given to the cars in which you carried baggage ?

A. When I first went there, our cars were like our baggage-cars now; then they built what was called a crate-car—a platform with crates—that you could haul on to the car and run on to the boat at Albany, to save time. All the baggage that crossed the river we had put into crates, to save time; otherwise we had to handle it all over, put it on a barrow, and wheel it to the boat. Our crates stood on the boat nights, and in the morning I used to go through and check my baggage, and put the Boston baggage into the Boston crates and the way baggage into others. They did that to save time, but it was a man-killer to save time; it nearly killed me.

Int. 7. State whether or not you were baggage-man on the crate-cars you have alluded to.

A. Yes, sir. The first crate that was built here was put onto my car, and I always run them, until they abandoned them.

Int. 8. Please state how you operated the brakes on such crate-cars.

A. I had to brake from Albany to Boston, and from Boston to Albany. My business was to brake just as much as the brakeman behind, and I had to do the baggage work, too. They worked the men then altogether different from what they do now.

Int. 9. What kind of brake, if any, was put on the crate cars ?

A. Well, what you call the Springfield brake was put on the crate-car—a double-chain brake, similar to this (referring to "Defendants' Exhibit, large Springfield brake, 124.")

Int. 10. Please state why such brake was put on the crate-car

1918 A. M'r Richard Welch, the man who ran on opposite days to me, was an Irishman. Before these double-chain brakes were put on, he had to run through before getting into Albany, and cut off the engine (that was his work and mine), and let the engine go into the round-house this side of Albany. It was down grade there, and the train all kept together until after we went through the canal bridge, and there the passenger cars were detached from the baggage car, and they would stop in the depot; and we run outside to the wharf, where we could let the platform down and run our cars right onto the boat. One day M'r Welch went off onto the float there with his car—I never happened to—and then they went to work and put on this brake, the same as they had on the tenders.

Int. 11. What have you to say of the operation of this old Springfield brake as applied to the crate cars ?

A. I always claimed it was a great advantage over the single brake. In the first place, if we were going west, we had to be on this end of the car, so as to brake two cars; going east, we would be on the opposite end. With the single brake, if we broke one brake, we only had the next car. After we had attached the old Springfield brake, I could operate on the opposite end from the one that was broken; it would operate on both trucks, but it wouldn't with the single brake. The moment the chain breaks, or the connection breaks, you lose the whole power. [The same as we had to-day. I have come up almost all the way from Boston with two men on. One had two double brakes, one had one double brake (these were the Hodge brakes), and one car behind had no brake at all. That was at the mercy of the Lord, if it broke off.]

(Counsel for plaintiff objected to the portion of the answer enclosed in brackets as immaterial, irresponsive, and volunteer.)

Int. 12. What trains are you now running on the Boston and Albany Railroad?

A. Five in the morning and half-past eleven in the morning,
1919 from here and return. We run two different sets of cars. The
cars I left this morning I get back to-morrow, at half past eleven; the cars I left Saturday morning I get back to-day, at half past eleven. My train stays one night at Albany; the other night at Boston.

Int. 13. What brake is applied to these trains that leave Boston at five o'clock?

A. They have the Hodge brake and the Springfield brake. The Springfield brakes come down to-day.

Int. 14. You have the Hodge brake on the cars of one train and the Springfield brake on the cars of the other train?

A. Yes, sir.

Int. 15. What difference, if any, have you noted in stopping the train on opposite days, from Boston out?

A. I don't know as there is any difference in the brake; there may be a difference in the days. You may take any brake—I don't care what brake it is—and you cannot always make your brake hold the same. It depends altogether upon the rails about the brake; but I do not know that there is any difference between one brake and another, in making stops one day as well as another. I cannot see any difference. I have been 33 years on the road, and have had a good deal of braking up to do myself, too.

Int. 16. Do you recollect there being put into your train a car with a Tanner brake on, a centre lever?

A. Yes, sir; I was shown and told of it at the time.

Int. 17. How long was that run in your train?

A. I cannot say now, exactly. I know I was told by the repair man there that that car wanted to be used, and used square and handsome, like the rest of them. They said they were trying the shoes, or something.

Int. 18. Did you note that car No. 123, with the Tanner brake, was put in the rear of the train every other day?

A. Yes, sir; I have noted it out of Boston.

Int. 19. And the same may be said of No. 124?

A. Yes, sir; there was a change every trip down there.

Int. 20. With what object?

A. To give them a fair test on the grades. I know there is an
1920 object with any brake. I will run one car behind six months and
they will not be even—the two cars won't. Any man of good common sense can go over these hills and tell you so. The hind end man, going down lots of grades, drags his wheels all the way, where the other man don't touch them. It is proper and square and just to change them. There is nothing unfair about it. Every man knows that we set the train by the hind car, coming up to stations; and going down these grades, there are lots of places where we have to haul the cars two or three miles by dragging the brakes.

Int. 21. Please state if, in your judgment as conductor of a train, the old Springfield brake is a safe brake for handling a train.

A. I never saw anything out of the way in it, unless it breaks. Anything is liable to break, you know. But if the brake is in working order, I don't think any man in the world could tell the difference. Put him on the car in the night, when he couldn't see the brake, and I don't think he could tell the difference. There is a difference in the rigging of them; but if he didn't see them, I don't think he would know the difference.

Cross-examined by M'r Cozzens:

Cr.-int. 1. The difference between what brakes do you mean?

A. Either the Tanner or the Hodge.

Cr.-int. 2. How do you know what the object of putting these particular cars, No. 123 and No. 124, in the rear of those trains on alternate days was, except, as you have said, what you have been told by the men? I refer to those particular cars; I am not asking about the object generally of changing rear cars.

A. I think I have stated it fairly enough; I think I have told you the object of it; and, furthermore, I told you the men said they must be changed because they wanted to test the two. That is square enough and fair enough. I have given you the reason why it was done, and why it was ordered to be done. It is a fair test, and it would be fair in no other way.

1921 Cr.-int. 3. What are the names of the brakemen who have broken on this train since the cars with the Springfield brake have been in the train?

A. One of them is named Gardiner. I don't know his first name. He is away now. He has gone to work for the Eastern Railroad, I understand. The names of the other men are Bartlett and Stevens.

Cr.-int. 4. What are their first names?

A. I don't know the first name of either one of those men.

Cr.-int. 5. Who took Gardiner's place when he left?

A. It is hard telling. M'r Bartlett was the middle man, and I put him back; but I have had three or four different men. My men are all mixed up now. One of my brakemen is acting as baggage-master. My baggage-master is off on a furlough, but will be back to-night or tomorrow, and then the man goes to braking again. Bartlett was the middle man, and when Gardiner left I put Bartlett back on the hind end, where Gardiner broke; he has been the hind-end man for the last three or four months. The middle man is any man I can pick up. Sometimes he is a man from a freight train, and sometimes he is a man who has never run on a train anywhere. But I shall be all right in two or three days.

Cr.-int. 6. Do you know the names of all these men you have got to act as middle men?

A. No, sir. The man I have got to-day, I don't know what his name is any more than the farthest man in the world. My regular gang is three brakemen and a baggage-master. M'r Bliss is my baggage-master.

Cr.-int. 7. Then your regular equipment for that train is three brakemen?

A. Yes, sir, and a baggage-master.

Cr.-int. 8. How many cars are the regular equipment of that train?

A. We run out of Boston five cars. Going down, we run never less than five; sometimes six and seven. I sometimes take on cars at Worcester, but not often. Going down we have more than up. I

1922 hardly ever have more than five cars out of Boston; but coming in we sometimes have fifteen or twenty, just as it happens.

Cr.-int. 9. Have you given the names of all the brakemen who have been on this train from the time the car with the Springfield brakes first commenced running in it up to the time when M'r Gardiner left?

A. My impression is that there was a man by the name of Braman there when they were first put on.

Cr.-int. 10. Anybody else?

A. I don't remember any one else.

Cr.-int. 11. About how long was Braman on your train?

A. I think Braman was on there six or eight months, altogether. I can't tell exactly. Braman was on the hind end there for a long time.

Cr.-int. 12. Was Braman a good brakeman?

A. No, sir; he was not—not if I am a judge.

Cr.-int. 13. What was the matter with him?

A. Well, he would get drunk, and you want a man you can depend on. That is what I call a good brakeman.

Cr.-int. 14. What kind of a brake was used on the passenger-cars of what is now the Boston and Albany Railroad, formerly the Western Railroad, prior to the time when what you have called the old Springfield brake was put upon those crate cars?

A. Simply the single brake, which broke on four wheels only.

Cr.-int. 15. Was what you have called the old Springfield brake ever used on any passenger-cars on the Western Railroad before or after the time that it was put on those two crate cars?

A. Yes, sir; but not before to my knowledge. If my memory serves me, that was the first Springfield brake I ever saw on a car.

Cr.-int. 16. You say, not before. If such a brake was put on the passenger-cars of the Western Railroad after it was put on those crate-cars, on how many passenger-cars was it put?

A. I can't tell, sir. That is something I can't remember; but quite a number of them.

1923 Cr.-int. 17. You are sure that it was put on quite a number of passenger-cars, after being put on those crate-cars?

A. I am sure it was put on some of them; but I cannot tell, now, the number.

Cr.-int. 18. How long, after it was put on those two crate cars, was it put on those several passenger-cars?

A. I should not want to swear to that; but my impression is, it was pretty soon after. It could not have been long, I think.

Cr.-int. 19. Was it within a year after, to the best of your recollection?

A. I should say it was; still, I cannot fix any date, because I have no dates nor anything I can refer to. It is something I never laid up, you know.

Cr.-int. 20. Did you, when you answered that question, see M'r Whipple shake his head "No," to you?

A. No, sir; I have not looked at M'r Whipple.

Cr.-int. 21. Do you recollect anything about when the Hodge brake was first adopted on the passenger-cars of the Western Railroad?

A. Well, it was some time after. I couldn't say, sir. I was well acquainted with M'r Hodge. My impression would be, some two or three years; because I know M'r Gray and M'r Hodge had a brake controversy two or three years after the Springfield brake was put on the crate cars. I couldn't fix the time exactly; but I guess I am pretty near right.

Cr.-int. 22. How generally was the Hodge brake adopted on the passenger-cars of the Western Railroad at this time?

A. Well, it was quite a while before they got them on very extensively. They went on rather slow, after the road agreed to take hold of them.

Cr.-int. 23. Do you know whether the Hodge brake was being tested during this time that it was going on your road slowly?

A. I know when they put them on, we used them. I don't know as they were put on the road as a trial. I know we used them the same as any other brake when they were put on. I don't remember of any simple test about it, or any particular thing about it.

1924 Cr.-int. 24. Where did these several passenger-cars of which you have spoken, that had the Springfield brake on, run?

A. It would be pretty hard to tell. It was haphazard. Our cars, in those days, were all mixed up. Except those crate-cars, there were no cars that went through regularly. They might be left at Chatham, Pittsfield, Springfield, or Worcester, and we not see them again for a week.

Cr.-int. 25. More or less of them ran to Albany, did they?

A. Oh, yes.

Cr.-int. 26. How long did they continue to use the Springfield brakes on those several passenger-cars?

A. I don't know; for a long time. I don't remember anything about when they were taken off, or when they were done away with.

Cr.-int. 27. You have said that, to the best of your recollection, those Springfield brakes were put on those passenger-cars within a year after the Springfield brake was put on the crate-cars?

A. I didn't say so. I said they might have been put on within a year, and might have been more. My memory wouldn't tell exactly.

Cr.-int. 28. Do you think they were put on within two years?

A. Well, I should think they were; but not, I guess, generally. In fact, they never were on all of them.

Cr.-int. 29. Speaking of the several passenger-cars to which you have referred as having had the Springfield brake put on them after it was put on the crate cars, is it your best recollection that it was put on to those passenger-cars within two years after it was put on to the crate-cars?

A. I told you that, according to my idea, it was; but still it might not have been. I could not fix any date on that.

Cr.-int. 30. I only ask what is your best recollection.

A. Well, I have told you I couldn't recollect the time.

Cr.-int. 31. What is your best recollection; that it was within about two years?

1925 A. I cannot answer that question. I have answered it two or three times. I have told you it was put on; I can't tell the time. It might have been three months after, or a year and a half, or two years. I did not make any minute of the time.

Redirect:

Int. 22. May it not be that you are mistaken as to its being applied to passenger-cars at all, after being applied to the crate cars?

A. I think not. I think there were some put on. I may be mistaken, but I think there was. I think it was put on one or two of M'r Parker's cars. That is my opinion; but I may be mistaken. As my memory now serves me, they were put in those trains.

Int. 23. Whether the old Springfield brake, as applied to those crate cars, handled the cars as well, considering the state of the art at that time, as the same brake now applied to that train?

(Counsel for plaintiff objected to the question as grossly leading.)

A. I don't know of any difference between them. I never could learn much. I should hate to cuss one and praise the other to-day.

Recross:

Cr.-int. 32. Did you know M'r Ephraim Harris, head blacksmith on the Western road?

A. I used to know him, as being a blacksmith here.

Cr.-int. 33. Did you know that he got up those brakes that were put on those two crate cars?

A. No, sir; I don't remember now.

WILLIAM JENNINGS.

Deposition of John B. Adams.

Int. 1. What is your name, age, residence, and occupation; by whom employed, and how long so employed?

1926 A. John B. Adams; 57 years old; residence, Springfield; conductor upon the Boston & Albany Railroad, and have been for 32 years.

Int. 2. It has been said that a number of years ago two crate or platform cars were put upon the Western Railroad, now Boston & Albany Railroad, and that a new application of brakes was made to said cars. Do you know anything about it? If so, please state what you know, and the circumstances connected with such knowledge.

A. In the early days of the Western Railroad—in latter part of 1842, or fore part of 1843, I judge—we used the single brake; and in switching our cars at the Greenbush Station, when the crates were upon the car, the brakeman could brake only upon one truck; we made what we call a running switch. In one instance a crate or platform car ran through the passenger-house into the dock. Major Whistler, then civil engineer and superintendent, gave orders that no train should be switched at Greenbush without at engine. M'r Gray, then master-mechanic, suggested to M'r Harris, the blacksmith, if he could not attach an application for braking upon both trucks from either end of the car; and such a brake was perfected by Mess'rs Gray and Harris, or some one, and applied to the platform or crate cars, and was continued on those cars so long as they were in use for carrying baggage-crates.

Int. 3. Wherein did the brake applied as you have stated differ from the old single brake in its operation?

A. It differed by having an additional chain on the shaft running to the further truck. It was what is called the old Springfield brake.

Int. 4. Ephraim Harris has testified in this case "that the brakemen and conductor on the cars (crate-cars) found considerable difficulty and fault in the operation of those crate-car brakes," and one difficulty was in winding two chains on one windlass. "They would," he says, "override even so much as to destroy the brake on the car entirely." What have you to say on that point?

A. I have no recollection of knowing or hearing of any complaint of that kind as applied to those brakes on the crate-cars.

1927 Int. 5. Were you conductor on the train in which these crate-cars were used?

A. I was.

Int. 6. M'r Harris further testifies "that the short chain would prevent a car from turning on a curve." Was that so?

A. I think not—never knew of an instance of its preventing a truck from turning.

Int. 7. What about the fault-finding of the brakemen and conductor?

A. I have no recollection of any such fault-finding, other than would apply to any other brake. If the brake was in any way out of order they would complain.

Int. 8. M'r Harris has further testified "that the car had been thrown from the track in consequence of the short chain not allowing the truck to accommodate itself to the curves." What came under your observation on this point?

A. I have no knowledge of any such occurrence.

Int. 9. He has also testified "that this brake, at the time it was put on, was not intended to brake both ends of the car at once." What is your knowledge on this point?

A. It did brake on both trucks from either end of the car.

Int. 10. And he has further testified that "the brakemen considered that they could handle the car better with a single brake." What have you to say on this point?

A. I have no recollection of any such complaint.

Int. 11. And the said Harris has further testified that "this brake never had a trial to prove whether it was better than the single brake, or whether it answered the purpose for which it was designed." What say you to this?

A. I don't know of its ever having had a trial; but it answered the purpose for which it was designed.

Int. 12. What purpose do you understand the brake was to accomplish?

A. To brake on eight wheels from either end of the car at the same time.

Int. 13. Was this brake used to aid in stopping the trains at stations on the line of road over which the train was run?

A. It was.

1928 Int. 14. What was there about these platform crate or cars that made a double brake more desirable on them than on passenger-cars in the same train?

A. A brakeman, if necessary to use both brakes on a passenger-car, could do so by passing through the car while running; but on the crate-car he could not reach both ends of the car without climbing over the crates, which was very hazardous, and it would take a longer time to do it.

Int. 15. To what other cars, if any, about that time was this crate-car brake applied?

A. I think it was applied to one car called the directors' car.

Int. 16. Has the said brake, as applied to the aforesaid crate-cars and directors' car been applied to a train of five cars on the Boston and Albany Railroad?

A. It has.

Int. 17. Please look at "Defendants' Exhibit, Large Springfield Brake, 124," and state whether it correctly represents the brake so applied.

A. I think it is the same.

Int. 18. When was said brake first applied to this train?

A. I think it was some time in last January that the first car appeared in the train, and thereafter all the cars in the train were fitted up with the same brake.

Int. 19. Before a full train was fitted up with this brake was there, to your knowledge, an experiment tried in your train to test the com-

parative merits of two brakes in wearing out iron? If so, what brakes?

A. There was such an experiment; one was the Springfield brake, and the other the Tanner brake.

Int. 20. What suggestion did you make on the day the experiment commenced, that the test might be perfectly fair between the two brakes?

A. That the cars should be changed at every round trip; one car going ahead one day and the other the next.

Int. 21. What was your reason for suggesting the change?

A. The principal reason was inequality of men in braking. In de-
scending grades the car forward of the last car ordinarily gets
1929 more braking than the last car. Therefore we change braking
each alternate day, as the grades are different and longer on the
different sides of the mountain. By this changing I thought each car
would get an equal amount of braking.

Int. 22. From what point and to what point does this train run, and the distance?

A. From Boston to Albany—202 miles.

Int. 23. What part of this 202 miles do you run this train with said Springfield brake on, and from what place?

A. From Springfield to Albany—104 miles.

Int. 24. Do you return with the same cars the same day?

A. No, I do not.

Int. 25. What brake is on the train you take from Springfield to Albany the next succeeding day?

A. The Hodge brake.

Int. 26. What difference, if any, have you discovered in the stopping of the two trains on alternate days at stations, or otherwise, between Springfield and Albany?

A. I think our average stops are better when we have the Springfield brakes than the Hodge brakes.

Int. 27. How do you account for this difference?

A. I think the Springfield brake is better taken care of or kept in better order. I think the Springfield brake is equal to any other brake for handling a train.

Int. 28. In your judgment, has the value of the double brake been overestimated, as compared with the single brake, in supposing that it saves one-half the number of brakemen.

A. I think it has been overestimated. I think I can stop my train with three brakemen and single brakes on a dry rail as quick as I can with a double brake and three brakemen.

Int. 29. Were you from any cause obliged to dispense with a double brake and resort to a single brake, to what extent would you increase the number of brakemen to make your train as safe against accident as it is now with the double brake, all kinds of weather and condition of rails taken into account? Whatever your answer may be, please give a reason for it.

A. I think an increase of one man to a train more than I have
1930 with a double brake. The additional man would have one truck
to brake on, and could assist the other brakemen.

Int. 30. What grades do you run your trains over between Springfield and Pittsfield?

A. I couldn't say. I know the grades are very heavy.

Int. 31. For how many years did the Western Railroad continue to use single brakes after other roads had adopted double brakes?

A. I don't know, but quite a length of time.

Int. 32. To what extent has the speed of passenger-trains been increased since the years 1843 and 1844?

A. The time between Albany and Springfield has been decreased two hours for way-trains; that is to say, in 1843 the time was six and a half hours, and now it is four and a half hours.

Int. 33. To what extent has the weight of cars been increased in that time?

A. The weight of the passenger-cars has nearly or quite doubled, I think.

Int. 34. In your judgment, did the same necessity exist in 1843 for the use of the double brakes that exists at the present time?

A. I think not. Our trains in 1843 comprised only two cars, and occasionally three with the crate car; and always carried two brakemen, and a baggage-man, who broke on his own car.

Int. 35. As the number of cars on your train increased, did you increase the number of brakemen, while you used the single brake?

A. I think not.

Int. 36. Have you increased the number of brakemen since 1843?

A. Not regularly. I have run all this summer with two regular brakemen only. My regular train now is five cars. Occasionally I have an extra car.

Int. 37. Before adopting the double brake on your road, and when you had to depend entirely on the single brake to stop the train, did the engineer have to reverse his engine to prevent the train from running by stations?

1931 A. Not as often as he does now. Our stops at stations were better made then than now, in consequence of the trains being much lighter—the engines and cars lighter and more easily handled.

Int. 38. Are you obliged to stop your train, at any stations between here and Pittsfield, on a down grade? And, if so, name them.

A. We are; at Hinsdale and Dalton.

Int. 39. Have you had any trouble in stopping your trains at those stations with the old Springfield brake; or has the engineer been obliged to reverse his engine to prevent running by these stations?

A. We run by Dalton frequently; I think less with the Springfield brake than any other.

Int. 40. Do you mean by any other the Hodge brake, which is used on your train on alternate days?

A. I do; that is just what I mean.

Int. 41. Is there any reversing of engines in either case?

A. I don't recollect now of an instance of reversing at Dalton. We do not reverse to stop the train at the station often; but when we run by, and the brakemen fail to stop the train at the station, the engineer has to reverse to back up to the station.

Cross-examined by M'r Sayles, complainant:

Cr.-int. 1. Did your train run by Dalton Station yesterday morning; if so, how far by?

A. It did; about the length of the train.

Cr.-int. 2. Which brakes were on that train, the Hodge or the Springfield?

A. I do not know.

Cr.-int. 3. Did the Springfield brakes, that were on the two crate cars in 1843 and 1844, as you have stated, work as well as the Springfield brakes now work on the five cars on your train?

A. I think they did. I know of no reason why they did not. I

never heard of any complaint of the Springfield brake in 1843 and 1844.

1932 Cr.-int. 4. In your 15th direct answer you say that you think that the Springfield brake was applied to one car, called the "directors' car," about the time it was applied to the crate cars; do you know what the number of that car was; and what knowledge have you that it was applied to it about the time the crate-car brakes were applied?

A. I don't know that any car on the railroad had any number at the time inquired about. I don't remember any number of this car. I have a distinct recollection, I think, that the directors' car had the two chains attached to the staff. The car stood in the passenger-station at Greenbush, and was very little used. It would stand there six months, sometimes, without being used. My knowledge of its being put on about that time is my memory. I can't fix upon any definite time at which this brake was put on. It may have been three months, six months, or a year after the crate-car brakes were in use.

Cr.-int. 5. Will you swear that it was within a year after the crate-car brakes were in use?

A. No; I cannot fix any time definitely.

Cr.-int. 6. These brakes went out of use, didn't they?

A. As far as my knowledge goes, when the crate cars went out of use the brake went out of use.

Cr.-int. 7. Do you know how long that brake was used on that directors' car you speak of?

A. I do not.

Cr.-int. 8. You said, in your 37th direct answer, that before adopting the double brake upon the Western Railroad, and when you had to depend entirely on the single brake to stop the train, the engineer did not have to reverse his engine to prevent the train from running by the stations as often as he does now. What do you know about the engineer reversing his engine, or not reversing it, when the single brake was used?

A. I can always tell, as conductor in the car, by the motion of the car, or sudden reaction, when the engineer reverses to stop the train. The stop is more sudden than when the stop is made by the brakes alone.

1933 Cr.-int. 9. How often did the engineer have to reverse his engine to stop at stations, when the single brake was in use upon the Western road?

A. Very rarely to stop at stations.

Cr.-int. 10. How often does he do it now?

A. Not often.

Cr.-int. 11. Do you mean to say that when the single brake was used upon the Western road there was less necessity to reverse the engines to stop at stations than now, when the double brake is used on said road?

A. I say there is no necessity at all of reversing the engines if all the parties do their duty, and the engine-man his. It is where men neglect their duty that we have to reverse in either case.

Cr.-int. 12. (Question repeated.)

A. I say no; there was no more necessity.

Cr.-int. 13. How was the fact; was the engine more frequently reversed to stop the train at stations with the single brake than now with the double brake?

A. I think not. I speak of my own train. I have no knowledge of the stopping of other trains than my own.

Cr.-int. 14. How long is it since single brakes were used on your train?

A. I don't know the exact time; a number of years; I don't recollect how many. I can't state the year.

Cr.-int. 15. Can you tell the time within three or four years?

A. I can't pretend to tell any definite time; quite a number of years.

Cr.-int. 16. How many cars, on an average, run in your train at the present time?

A. Five and six, this summer; five is the usual number.

Cr.-int. 17. For about how long have you been running with five cars as the usual number?

A. I think for most of the time for a year past.

Cr.-int. 18. Previous to a year past, what was the usual number of cars run in your train?

A. I think we have averaged five cars for two or three years past.

Cr.-int. 19. Prior to three years ago, how many cars did you run, usually, in your train?

1934 A. As many as four.

Cr.-int. 20. Can you tell for how long a time, prior to three years ago, your train averaged as many as four cars?

A. I think our train in summer would date back ten or twelve years, or more, with four cars. The train consisted of a baggage-car, second-class car, and two passenger-cars. Some of the passenger-cars with seats for 76 persons, and others going down to 62 seats.

I mean to say, the time has gone back fifteen years from the present, and even more.

Cr.-int. 21. Will you state the names of some of the engineers, who are now living, who ran your train at the time it had single brakes on it?

A. Darius Wood; a man by the name of Adams, don't know his first name; George Whitney.

JNO. B. ADAMS.

Deposition of Charles W. Marsh.

Int. 1. Please state your name, age, residence, and occupation.

A. My name is Charles W. Marsh; age, 43; residence, Albany; occupation, conductor on the Boston and Albany Railroad.

Int. 2. How long have you been conductor on that road?

A. Twenty years.

Int. 3. Between what points do you run on that road?

A. Albany and Springfield.

Int. 4. What time does your train leave Albany?

A. 6.30.

Int. 5. For the last five or six months, have you been running trains out of Albany, on alternate days, having different brakes applied to the same?

A. We have.

Int. 6. What brakes on one train, and what on the other?

A. The brake called the Hodge brake on one train; the old Springfield brake on the other.

1935 Int. 7. In running these trains on opposite days, please state whether or not you have discovered any difference in the stopping of the trains at stations?

A. I do not see that we make any more effort to stop. The trains are stopped exactly with the same brakes and the same men.

Cross-examined by M'r Cozzens:

Cr.-int. 1. Have you noticed where the brakemen begin to apply the brakes in stopping at the stations with either of those trains?

A. I don't know that they use any more effort.

Cr.-int. 2. That is not my question. Have you noticed where they begin to apply the brakes?

A. Generally they begin to use the brake as soon as the engineer shuts off, at the proper distance from the stations to stop the train.

Cr.-int. 3. Will you now answer my question? Have you noticed where the brakemen begin to apply the brakes in stopping at the stations with either of these trains? "Yes" or "No." Whether you have noticed; that is all I ask.

A. I have taken a little notice.

Cr.-int. 4. And having noticed, you say what you do?

A. I do, sir.

CHARLES W. MARSH.

Deposition of W'm W. Stevens.

Int. 1. What is your name, age, residence, and occupation?

A. My name is William W. Stevens; age, 34; residence, No 2 Shawmut Place, Boston; occupation, brakeman on the Boston and Albany Railroad.

Int. 2. On whose train, running on the Boston and Albany road?

A. William Jennings'.

Int. 3. To what point from Boston does that train run?

A. Springfield.

Int. 4. And from thence to what place?

A. To Albany.

1936 Int. 5. You are a brakeman on this train from Boston to Springfield?

A. From Boston to Springfield, and from Springfield to Boston.

Int. 6. Do you take back the same train that you bring in?

A. No, sir; I do not.

Int. 7. Does the train that goes through from Boston to Albany to-day return from Albany to-day or lie over?

A. It lies over in Albany and returns to-morrow.

Int. 8. Then I take it there are two trains sent out on alternate days from Boston?

A. Yes, sir.

Int. 9. What kind of brake do you have on one train, and what kind on the other that run on opposite days?

A. One has the Hodge brake, the other has the Springfield.

Int. 10. Have you, as brakeman, operated those brakes on opposite days from Boston to this place?

A. Yes, sir.

Int. 11. What is your method, as brakeman, as to time and place of applying the brakes to bring the train to rest at the station?

A. I have no particular point that I set at which I brake. I brake by the way the train is going and how fast it is running.

Int. 12. In the absence of any signal, do you put on the Springfield brake any quicker to bring the train to rest, or at any greater distance from the station than the Hodge brake?

A. I don't, if they are rightly adjusted.

Int. 13. How are the brakes running now, and how have they been running for some time past?

A. They have run very well for the last three weeks.

Int. 14. Has there been some time in which they did not operate as well?

A. There has. Here, about four or five weeks ago, they did not work so well as they have for the last three weeks.

Int. 15. Does it happen sometimes that the Hodge brake does not work so well as it does at others?

1937 Yes, sir, it does. The Hodge brake that came on to-day, there is one end of the car that works very bad. In some places we do not use that end of the car so much as we do the other. We use that mostly in making up the train.

Int. 16. What provision is there in the Hodge brake itself for taking up the wear of the shoes, providing it is neglected by the inspector of cars at the station?

A. You can wind up on one end and set the dog, and then brake on the other and take up part of the slack.

Int. 17. Have you any such provision in the old Springfield brake?

A. We use that on both ends.

Int. 18. I understand by that, that the two brakemen can apply the Springfield brake?

A. You may take the Springfield brake, and you may set one brake on one end of the car, and the other brakeman can wind it up on the other end; and, when he has wound upon it two or three times, you can set it up two or three notches more. After he has set the brake, the other brakeman cannot let it off without some one assisting him.

Int. 19. Can the same be said of the Hodge brake?

A. No, sir.

Int. 20. When the brake is set up firmly at one end, can you set it up further at the opposite end?

A. No, sir.

Int. 21. When the Springfield brake is properly taken care of, in your judgment is it a safe brake applied to a whole train?

A. Yes, sir; I think it is.

Int. 22. As the brakes are now running on the train in which the old Springfield brake is used, what difference, if any, in your judgment, would there be in stopping a train with said brakes, and stopping the other train with the Hodge brake, provided there was a sudden sharp call to stop from the engineer?

A. I have not been on that train for the last three days. When I left the train the brakes were in good shape, and I could stop the train with the Springfield brake as quick as I could with the Hodge
1938 brake, and with less work. I can set the Springfield brake
quicker, when it is properly adjusted, the chains in proper shape, than I can the Hodge brake. That is, I can set the Springfield brake easier, with less work, than I can the Hodge brake.

Int. 23. You speak of being off three days; where were you during that time?

A. I was in the baggage-car.

Int. 24. Are you now running as baggage-man on that train?

A. Yes, sir.

Int. 25. Been promoted from brakeman to baggage-master?

A. I am taking the baggage-master's place; he is gone for ten days

Int. 26. Who has operated the brakes in the rear of these two trains until within a few days?

A. Well, they have not had any one on one day, and two days they have had on another man. I don't know his name. He has usually broke on the "Owl" train.

Int. 27. Who is acting as brakeman on the rear of this train, at the present time?

A. M'r Bartlett.

Cross-examined by M'r Cozzens:

Cr.-Int. 1. How long have you been brakeman on Jennings' train?

A. Nine months.

Cr.-int. 2. Had you ever been brakeman on that train before?

A. No, sir.

Cr.-int. 3. You think the Springfield brake is a first-rate brake, do you?

A. I think it works very well, when it is in proper shape.

Cr.-int. 4. Do you think it is as good as the Hodge brake?

A. I think I can stop a train as quick with the Springfield as with the Hodge brake, when properly adjusted, with the same speed.

1939 Cr.-int. 5. When you have taken up the slack, as you have described, with the Hodge brake, by taking a short turn around the windlass shaft, at one end of the car, you cannot brake, can you, except at one end of the car, as long as that arrangement is continued?

A. Why, you set up one end, and then you can go and brake on the other.

Cr.-int. 6. You have to keep on that other end as long as that arrangement continues?

A. Yes, sir.

Cr.-int. 7. You cannot brake only at one end, as long as that arrangement continues?

A. No.

W'M W. STEVENS.

Deposition of John Bartlett.

Int. 1. Please state your name, age, residence and occupation.

A. My name is John Bartlett; age, 25; residence, Boston; occupation, brakeman on the Boston and Albany Railroad.

Int. 2. On what trains?

2. William Jenning's.

Int. 3. The same trains as described by the previous witness?

A. Yes, sir.

Int. 4. On what part of M'r Jennings' train do you act as brakeman at the present time?

A. The rear.

Int. 5. What two cars did you operate upon this morning, in coming in, with the Springfield brake?

A. No. 123 and No. 124.

Int. 6. Which car comes in the rear?

A. No. 123.

Int. 7. Do you find any difficulty now in taking the slack of the train, and holding the train as it ought to be?

1940 A. I find no difficulty now, sir, since I have been on the rear end of the train.

Int. 8. Previous to occupying the position on the rear end of the train, on what part of the train did you act as brakeman?

A. In the middle of the train.

Int. 9. How many brakemen operate this train?

A. Three.

Int. 10. How many cars compose it from Boston to this place?

A. Five cars, sir.

Int. 11. Is it often increased by any other car or cars?

A. No, sir, not coming from Boston this way.

Int. 12. How is it in returning to Boston?

A. Our train has six cars coming east, and sometimes we take seven.

Int. 13. Always five coming west?

A. Yes, sir.

Int. 14. And you always have the Springfield brake one day and the Hodge brake the other?

A. Yes, sir.

Int. 15. In the event of a sudden call from the engineer to stop, by being flagged, or for any other cause, can you bring one train to rest as quick as the other, at the same speed?

A. I think there isn't any difference now; I can't see any difference. I had a trial yesterday with one brake, and this morning with the other.

Int. 16. What advantage, if any, has the Springfield brake over the Hodge brake?

A. Well, I think there is one advantage; you can set the Springfield brake up on both ends of the car, and it will operate on both ends at a time, and on the Hodge it will not. I think that is the advantage.

Int. 17. Wherein is the Hodge brake, in some respects, better than the Springfield brake?

A. Well, with the Hodge brake, if the chain is too long, and you wind
the rod up so that it brings up to the post, by going back to the
1941 rear, and taking up the slack of the chain, will work better than
the other brake. I don't know any other advantage the Hodge
brake has over the Springfield brake. That is the only point I can see
now.

Int. 18. Do you mean by "the post" the brake shaft on which the chain winds?

A. Yes, sir.

Int. 19. Would it or not make any brake inoperative, if the chain was so long as to bring the hook up against the brake-shaft?

A. Yes, sir, it would.

Int. 20. On which car are the chains the longer—on 124 or 123?

A. On 124.

Int. 21. Do you know how long the chains are on 123?

A. No, sir; I don't know the exact length.

Int. 22. All the brakes on the train in which the Springfield brake is used have two chains winding on each windlass?

A. Yes, sir.

Int. 23. Does "Defendants' Exhibit, large Springfield brake, 124," appear to be the same as you are using on the train which you came in on this morning?

A. Yes, sir; that is the same.

Cross-examined by M'r Cozzens:

Cr.-int. 1. When did you commence to be brakeman on M'r Jennings' train?

A. The first of last November.

Cr.-int. 2. Had you ever been brakeman on that train before that time?

A. No, sir.

JOHN BARTLETT.

Deposition of Henry F. Taylor.

Int. 1. What is your name, age, residence and occupation?

A. Henry F. Taylor; 26 years old; reside in Springfield, Mass.; by occupation, brakeman.

1942 Int. 2. How long have you been brakeman; and upon what railroad and upon what train?

A. I have been brakeman nearly five years, upon the Boston and Albany Railroad, on Conductor John B. Adams' train.

Int. 3. When does his train leave Springfield, and to what place does it run, and when does it return to Springfield?

A. It leaves Springfield at 9.10 a. m., runs to Albany and returns, reaching Springfield at 7.30 p. m., same day.

Int. 4. What brakes are in general use upon the passenger-cars of the Boston and Albany Railroad?

A. The Hodge brake.

Int. 5. What other brake or brakes, if any, have been used on the train upon which you are brakeman?

A. There is a brake used called the Springfield brake, and also a Tanner brake.

Int. 6. On what car did you first see and use the Springfield brake, and on what car the Tanner brake?

A. Passenger-car No. 124, the Springfield brake; and No. 123, the Tanner brake.

Int. 7. About what time did the two cars named, with the aforesaid brakes thereon, come into Conductor Adams' train?

A. I think along about the last of January, the 29th or 30th, 1872.

Int. 8. Were these cars with the aforesaid brakes on, coupled the one to the other? If so, in what part of the train did they run, and who operated the brakes?

A. They were so coupled in the rear of the train—the two rear cars. I operated the brakes myself.

Int. 9. What change, if any, was there made in running cars Nos. 123 and 124, from the time they came into Conductor Adams' train, for six or eight weeks thereafter?

A. The Springfield brake would be behind one trip, and the Tanner the next; and so continue to alternate during the time stated.

Int. 10. How often did you work the two brakes, and from what point to what point did you work them?

A. I worked them at every regular station, and whenever called on to work them.

1943 Int. 11. During the time you worked the aforesaid brakes, did you apply one as strongly and efficiently as the other.

A. Just about the same.

Int. 12. So far as the holding of the brakes on their respective cars, what conclusion did you come to as to the comparative holding-power of the two brakes?

A. I didn't notice much difference, except that one seemed to work a little stiffer than the other. I think the Tanner worked a little stiffer than the Springfield.

Int. 13. What do you mean by one's working a little stiffer than the other?

A. I don't think I could apply the Tanner brake as quick as the Springfield. What I mean by that is, that I think I could take the slack of the train a little quicker with the Springfield than the Tanner brake.

Int. 14. You say you think the Tanner brake works a little stiffer than the Springfield. Do you mean by that that it feels more rigid in applying power to the brakes?

A. Yes, sir,

Int. 15. What brake is now in use on car No. 123?

A. The Springfield brake.

Int. 16. Have you noticed whether there is any difference in length of chains on No. 123 as compared with 124?

A. I have never noticed it.

Int. 17. In operating the old Springfield brake on No. 123, have you noticed that, when the wear of the brake was not taken up, the rods, in applying the brake, came up solid against the windlass-shaft upon which the chains are wound?

(Objected to.)

A. I have noticed when the shoes are worn that the connection-rods come up close against the brake-staff, and we run by the station. This has been the case a number of times. What I mean by that is, that the connection-rod came up against the shaft so as to shut off the power from the wheels.

Int. 18. When the wear of the shoes is properly taken up on the Springfield brake, how many times can you wind the chains around the windlass-staff before the brakes are firmly set?

1944 A. I couldn't say exactly, but I should say about four times; three or four times.

Int. 19. How many to set the Hodge brake?

A. I should say four times to that.

Int. 20. How many to the Tanner brake?

A. I have not noticed much difference, perhaps not as many; but I should say there was not much difference.

Int. 21. What days in the week does the train having the Springfield brake on run from Springfield to Albany? And what days the Hodge brake?

A. I think the Hodge brake runs Mondays, Wednesdays, and Fridays; the Springfield the other days.

Int. 22. Do you operate the brakes on the rear cars of the two trains, on alternate days, between Springfield and Albany?

A. I do.

Int. 23. What has been your observation as to the time of stopping the two trains at stations on alternate days?

A. I don't think we stop quite so quick with the Springfield as the Hodge brake. I don't have to use so much strength to stop the train with the Hodge as with the Springfield brake.

Int. 24. Do you, as a general rule, make what would be called good stops one day with another, without reference to which of the two brakes you have on the train?

A. I think we make better stops one day than another.

Int. 25. May this happen or not on any day?

A. We get by the station many times with the Hodge brake. We have run clear by West Springfield with the Hodge brake. What I mean by running by is, that the baggage has had to be carried two rods to be put into the car from the point where the train ought to have stopped.

Int. 26. Do you with the Hodge brake run by at Dalton so as to have to back up the train?

A. Yes, sir. We got by there about a week ago, and had to back the train up.

Int. 27. What reason can you assign for running by that station on any day?

1945 A. I think sometimes the engineer has something to do about stopping the train. M'r Sherts is our engineer; and he sometimes runs clear up to a station before he shuts off steam, and don't give us a chance.

Int. 28. Are you acquainted with M'r Sayles, the complainant in this case; if so, when did you first make his acquaintance?

A. I know M'r Sayles. I made his acquaintance about two weeks ago.

Int. 29. At that time, what did he wish to learn from you, and what reply did you make?

A. He asked me if I knew where Ed. Wood was. I told him I heard he was in Worcester. He then asked me if he didn't use to brake on the train with me. I told him yes. He then asked me if he was a good brakeman. I said he was. He then asked me how I liked the new brake we were using—the double-chain brake. I told him I didn't think so much of it as I did of the Hodge brake; that I thought the Hodge brake was a better brake—that is, it worked better.

Int. 30. After the interview, when did M'r Sayles meet you again; and what did he want then?

A. He met me the next night, on the arrival of my train from the West. He asked me if I was called on as a witness, would I say I liked the Hodge brake the best. I told him I would.

Int. 31. When, thereafter, did he again meet you; where, and what further did he want of you?

A. He met me the next morning at my boarding-place—Cooley's restaurant—and wanted to know if I would keep track of the number of times we got by stations that day, if we did get by. I told him I would.

Int. 32. Did you get by; and, if so, how many times?

A. The next time I saw him I told him I didn't recollect of getting by any station that day. We had on the Springfield brake that morning.

Int. 33. Thereafter when did M'r Sayles meet you; and where, and what did he want?

A. I think it was at my father's house, at Westfield, some ten miles from Springfield, on Sunday, a week ago last Sunday. He then 1946 asked me where this Mallory was who used to brake with me. I told him he lived up about four miles from there. He wanted to know if he knew anything about the Springfield brake; if they were using it when he was on. I told him, No, he wouldn't know anything about it; for we were not using it at the time. I don't think of anything more at that time. I told him I was coming to Springfield on the early train Monday morning, and he could see me there.

Int. 34. Did M'r Sayles make any inquiries of you about the Springfield brake, at your father's house in Westfield, or ask you to make any statements, or give any evidence in relation to it?

A. I think he did. He wanted to know if I would testify in court, if I should be called on, about running by stations with the Springfield brake. I told him I would. I told him that perhaps the company might not like to have me speak my mind about the brakes; that I might possibly do something and be discharged. He then said that he didn't think they would do any such thing; but, if they did, that I should have a better situation than I held now; but he didn't think they would. He told me that all the time I was out of work, if I should be discharged, that he would pay me as much or more than I was getting now, and see that I had a better situation.

Int. 35. In short, what did he want you to testify to about the old Springfield brake?

A. He wanted to have me say the brake was not as good as the Hodge brake. I told him a great many times that the Springfield brake wasn't adjusted, or fixed, as it should be; that when the shoes got worn thin, they didn't work well, so that we couldn't hold the train. I then said that when the rod came up against the staff, it didn't work well, of course.

Int. 36. Has or not M'r Sayles wished you to testify that the Springfield brake is a very poor brake, unreliable and unsafe to run a train with?

(Objected to.)

1947 A. He asked me if I was willing to testify to the facts that I knew about the brake just as I knew them. I told him yes. I then told him that, if the brakes were in good repair and the shoes not worn, the train could be stopped by using more strength; but couldn't be stopped so easy, and not quite so quick. I then told him there were quite a number of cars with the Hodge brake on, where the brake beams were not hung right; they being either too high or too low, so that they didn't hold any better than the Springfield brake.

Int. 37. Did or not M'r Sayles convey to you the idea that he wanted you to testify that the Springfield brake was unreliable and an unsafe brake?

A. I think he did.

Int. 38. You will now please state whether, in your judgment, the Springfield brake, when properly adjusted, and the wear of the shoes properly taken up, is a safe brake with which to run a railroad train?

A. There would be no more trouble about stopping a train, by using more strength, with the Springfield brake than the Hodge. It is harder for the brakeman. I don't see any difference now in stopping the two trains, one with the Hodge and one with the Springfield, now that we have three men. We have been running with two.

Int. 39. Please state whether, in the operation of the old Springfield brake, you have known of the two chains overriding or overlapping each other on the brake shaft?

A. No, sir; I never have.

Int. 40. Have you or not observed any difference in the holding of cars, by said brake, when the train is running upon a curve or upon a straight track?

A. I have never noticed any difference.

Cross-examination by complainant:

Cr.-int. 1. Did M'r Sayles, when he saw you, several times, some days ago, as you have stated, tell you, that, if you was called upon to testify in this case, that all he wanted was the facts in the case, just as you had stated them to him, with regard to the working of the old Springfield brake?

1948 (Objected to, as it does not fully appear in the record what facts the witness was made to state in reference to the matter inquired of.)

A. I told M'r Sayles I would testify to the facts just as I had told them to him. M'r Sayles said to me, "That is all I want."

Cr.-int. 2. Did he, at any time, ask you to testify to anything in this case that you had not told him was true?

A. No, sir.

Cr.-int. 3. You have stated that the Springfield brake worked harder than the Hodge brake; did you tell M'r Sayles that, when you had the Springfield brake on your trains, you were obliged to commence applying the brakes, in order to stop at the stations, about twice as far from the station as when you had the Hodge brake on?

A. I told M'r Sayles I generally had to commence putting on the brakes farther back, when I had the Springfield brake, than the Hodge brake. I am obliged to, to stop at the station. I mean that I had a green man on who didn't understand the grades, and had to commence sooner. He was also on when we used the Hodge brake.

Cr.-int. 4. Did one of the engineers that hauled your train between here and Albany ask you at any time why you didn't hold the train one day as well as another.—that he had noticed every other day they made better stops at stations than on alternate days?

A. M'r Gettes, who did run from Pittsfield to Albany on this train, asked me why it was that we used to drag into some of the stations so. I said because we have to commence to brake sooner with the brake we are using to-day; that it don't hold as well as the brake we shall have to-morrow. He said, "Don't commence quite so soon, and I will help you—I will throw it over."

Cr.-int. 5. Did he help you stop after that, by reversing his engine when you had the Springfield brake on your train?

A. He would sometimes; but there were flag-stations along on
1949 the road, and it wasn't always that I knew he was going to stop
at such and such stations. At U. Edwards station, for instance,
I could not sometimes see M'r Adams make a motion to stop; and it is impossible sometimes going around curve for the brakeman to see the signal; then, of course, we run by, and then the engineer has to help us. It was not often that I failed to see the signal.

(All after the words "He would sometimes," in the above answer, was objected to by complainant, as drawn out by the remarks of the defendant. Objection objected to, as not stating the matter correctly.)

Cr.-int. 6. Did you not, a few weeks ago, while going from here to Albany with the train having the Springfield brake on, run the whole length of the train by the station at East Chatham, when Superintendent Russell was aboard the train, and did you not tell M'r Russell that you had commenced braking way back by the "grave-yard," and was unable to stop the train at the station with those brakes?

A. I told M'r Russell that I didn't know what was the matter with those brakes. He made no reply. After I got to Chatham, I told M'r Adams that I was sorry to make such a stop as we made at East Chatham; and both of us got down and looked under the cars. I saw the shoes were worn very thin, and the connection-rod come clear up to the staff. I stepped to the rear of the car and turned up the brake, to see if I could take up a little of the slack. I saw it did no good in the stopping of the car. When I got to Albany, I told the train men there, that, before that car went back, they would have to take up considerable of the chain, or fix it in some way, as it wouldn't work.

(The above answer was objected to as not responsive to the question, and the witness then resumed.)

We did not, at the time mentioned, run the whole length of the train by said station; we run about one car's length too far. I told M'r Russell that I had commenced braking way back by the "grave-

1950 yard.” I think I did not tell him I was unable to stop the train at the station with these brakes; but I told him I did not like those brakes as well as I did the other kind.

Cr.-int. 7. What other kind did you mean?

A. I meant the kind that were on the other train, the Hodge brake; but I did not know they were the Hodge brake then.

Cr.-int. 8. Have not you, and the other brakemen that have run on the same train with you, often complained of this old Springfield brake between yourselves, about its working so hard?

A. We have. They work hard.

Cr.-int. 9. Have you not often dreaded getting on the train with the Springfield brake, on account of its working so hard, when your hand was very sore from working so hard on the said Springfield brake?

A. I can't say I dreaded that any more than any other brake when my hand was sore.

Cr.-int. 10. Did you tell M'r Sayles that your hand had become very sore from being obliged to work so hard to stop the train with the Springfield brake?

A. No, sir; I never told him so. I did tell him I never had such looking hands as that, before I used the Springfield brake; that I had to pull a great deal harder with this brake. I never wear gloves.

Cr.-int. 11. What was the condition of your hand when you showed it to M'r Sayles?

A. It was calloused, but no sores were on it. The callous was 1¼ inch wide, and 2 inches long; but it don't trouble me any.

Cr.-int. 12. You say you did not dread the Springfield brake more than any other brake; and you have also said that you had to work a great deal harder with that than with the Hodge brake. Please explain this matter.

A. I don't know as I ever got on a train when I dreaded anything about the brakes. Still, I know the Springfield brake worked harder than the Hodge.

Cr.-int. 13. Did you ever complain to M'r Adams, the conductor of your train, about the Springfield brake working hard?

1951 A. I have told M'r Adams that they worked harder than the Hodge brake.

HENRY F. TAYLOR.

Deposition of Charles Haradon.

Int. 1. What is your name, age, residence, and occupation?

A. Charles Haradon; age, 23; residence, Springfield; occupation, brakeman on the Boston and Albany Railroad.

Int. 2. How long, in all, have you been brakeman on the Boston and Albany Railroad?

A. Three years, last May.

Int. 3. On what passenger-trains have you run as brakeman, during that time?

A. On M'r Clark's train, east, and M'r Adams' train, at present, west.

Int. 4. Were you acting as brakeman on M'r John Clark's train, last fall and winter?

A. Yes, sir.

Int. 5. While acting as brakeman on his train, did cars No. 123 and No. 124 come into that train for service?

A. Yes, sir.

Int. 6. About what time?

A. About December, I think.

Int. 7. On what part of the train were those two cars used?

A. The rear.

Int. 8. And did you operate those two rear cars as brakeman?

A. I did.

Int. 9. Please look at "Defendants' Exhibit, Large Tanner Brake, 123," and state whether that brake, or one like it, was in use on car No. 123, in that train?

A. I should say it was.

1952 Int. 10. You will now look at "Defendants' Exhibit, Large Springfield Brake, 124," and state whether that car had such a brake in use on it while you operated it as brakeman in Clark's train.

A. I should say it did. I had a double chain, at any rate.

Int. 11. At what time did M'r Clark's train leave Springfield?

A. At quarter past seven, in the morning; leaving Boston at three, in the afternoon.

Int. 12. What orders did you receive in regard to the disposal of the two cars, 123 and 124, at Boston, for Springfield?

A. I was ordered to send one of the cars up on the accommodation train; M'r Clark said I could send up which one I chose; the other we kept until three o'clock, for the rear end of the express-train.

Int. 13. Which went on the end of the express train?

A. No. 124.

Int. 14. And which on the accommodation?

A. No. 123.

Int. 15. Why did you send 123 up on the accommodation, instead of 124?

A. Because, in switching the train at Worcester, 124 would in that way come behind always.

Int. 16. Why did you wish to have 124 come behind, instead of 123?

A. That was my preference, because it was always customary to get the easiest and best brake behind, as far as I knew how.

Int. 17. Why did you put 123 onto another brakeman to come up with on the accommodation train, instead of 124?

A. On the principle always to look out for No. 1, I suppose. I had the choice as to which I should have, and I never knew he had anything to say about it.

Int. 18. So you took 124 to come up on the express, and gave to another brakeman 123, to come up on the accommodation?

A. Yes, sir.

Int. 19. How long, as near as you can recollect, did you operate the two cars as brakeman, in Clark's train?

1953 A. I can't say just how long, for I don't remember. I know I had them for a while, and they were taken away. Might have been a couple of months or more, or not so much, exactly; I don't know.

Int. 20. Which brake, in your judgment, having handled both, seemed to be the more effective in taking hold of the wheels of the car to which it was attached, in the work of bringing it to rest?

A. No. 124 always seemed to work the freest and take hold the best, with the least power.

Int. 21. I suppose they were both good brakes, so far as holding the car to which they were applied, respectively, was concerned?

A. Either would hold the train.

Int. 22. There would be no difficulty, I take it, in taking the slack of the train with either in the rear?

A. Yes, either would take the slack of the train.

Int. 23. You say you ran No. 124 from Boston to Springfield in the rear; which did you run in the rear from Springfield to Worcester, and thence to Boston?

A. No. 123.

Int. 24. And those two cars always ran in the rear of Clark's train?

A. Yes, sir; unless we had extra cars. Sometimes we put an extra car behind; very seldom, though.

Int. 25. You speak of being brakeman on M'r Adams' train; when did you commence as said brakeman?

A. The third day of June.

Int. 26. To what point does M'r Adams' train run from this place?

A. To Albany.

Int. 27. When you came on to his train as brakeman, what brakes did you find on the trains running on alternate days from Boston here, and from here to Albany?

A. I found the double chain brakes running one day; and Hodge's brake, so called, running the other.

Int. 28. What other name have you heard the double chain brake called besides that name?

A. The old Springfield brake.

1954 Int. 29. Had you gone out on the train this morning to Albany as usual, what brake would you have had to rely upon to hold the train, as far as you had anything to do with it?

A. I should have had the old Springfield brake.

Int. 30. And on next Monday morning, what will you have?

A. Hodge's brake, so called.

Int. 31. Please state with what success you have met, one day with another, in stopping these trains at the several stations on the line between here and Albany.

A. As good success as ordinarily with any brake.

Int. 32. Do you operate the brakes on the train as rear or forward brakeman?

A. Forward brakeman.

Int. 33. How many cars compose this train all Springfield brakes?

A. There are only four in use. There were five cars in the train. I believe they all had the old Springfield brake.

Int. 34. How many brakemen on that train between here and Albany?

A. Two.

Int. 35. Do I infer, then, correctly, that the train is controlled by the brakes on four cars, although five may be equipped with brakes?

A. Yes.

Int. 36. Who operates the two cars in the rear of the train?

A. Henry Taylor.

Int. 37. And you the two cars next to his, I take it?

A. Yes.

Int. 38. Have you operated the brakes on No. 123 and No. 124 since you became brakeman in M'r Adams' train?

A. No. 124, I have.

Int. 39. How does it work, compared with the working of it when in M'r Clark's train?

A. I can see no difference.

Int. 40. When properly adjusted, and the wear taken up, do you deem the Springfield brake a safe brake on which to depend to control a whole train of cars, with a proper number of brakemen, such as are given to double brakes?

1955 A. Yes, sir.

Int. 41. In the use of the Hodge brake, what method have you, in the brake itself, for taking up the wear of the shoes, providing it is neglected by the proper person to take up such wear or slack?

A. We can take a short turn on the chain on the opposite end of the car from the one on which we are braking, and set down the dog in the ratchet and hold it there.

Int. 42. And then what do you do?

A. Then I go to the opposite end and use it the same as though it were adjusted by the man at the shop.

Int. 43. Do you find that same protection against excessive wear of the shoes in either the Tanner brake or the old Springfield brake?

A. No.

Int. 44. If the wear is not taken up, then, properly, at the shop, you have to go with it until such time as it is taken up?

A. Yes, sir.

Int. 45. What effect would either of those brakes, the Tanner or the Springfield, have on applying power to the wheels, if the chain become so slack as to wind up on the windlass to the hook, and become solid before the power from the windlass reached the wheels?

A. The train would be very likely to run a good ways before it stopped, and run by the stations.

Int. 46. But if such a thing should happen on the road with the Hodge brake, you could take up the wear on the opposite end?

A. Yes, sir.

Cross-examined by M'r Cozzens:

Cr.-int. 1. As to holding the train, do you consider the Springfield brake as good as the Hodge brake?

A. No, sir; I don't.

Cr.-int. 2. Did you see M'r Whipple nod his head "No," before you made this last answer?

A. No, sir; I did not.

Cr.-int. 3. Sure? Didn't you see him shake his head, "No?"

1956 A. I did not; I was not looking at him.

Cr.-int. 4. You have stated above that you had as good success with these trains, one day with another, one of which had the Hodge brake and the other the Springfield brake, as with any brake. What do you mean by that answer, if you consider the Springfield brake not so good as the Hodge brake?

A. Well, there is such a thing as having two different brakes that are not just alike, and still stopping the train with them, and stopping it at the same place. One works easier than the other; does not require so much power or so much caution in using.

Cr.-int. 5. Why did you say you had as much success, one day with another, as with any brake, ordinarily, if you consider that there is a difference between the Springfield and the Hodge, as to holding the cars?

A. Well, I knew each day what sort of brake I had to use, and made allowances accordingly.

Cr.-int. 6. When the days came when you knew you had the Springfield brake, what allowance did you make for that?

A. I knew I had got to work harder, perhaps, to effect the same result.

Cr.-int. 7. "Perhaps." Don't you know it? Recollect, you are on our oath. Don't you know it? Don't you have to work harder, almost every time you stop a train with it? Think before you answer, and answer categorically.

A. I said that I considered the Hodge brake the best, because it worked the easiest.

Cr.-int. 8. That is not the question. Answer the question put to you. (Question repeated.) Now answer the question I ask, and not some question which I don't ask.

A. Yes, sir.

Redirect:

Int. 47. Did you have any different points at which to apply the brakes to stop the train at the stations one day from those you had on another, or did you have the same point of applying it on both days, at any station?

1957 A. I do not brake by marks. I brake according to the speed the train is running, with any brake.

Int. 48. Does the engineer give a signal for brakes; and, if so, what is the signal, before he reaches a station at which he wishes to stop?

A. I know of no signal from the engine for applying the brakes, unless the engineer wishes to stop immediately, which is one short whistle for brakes. The orders of the road require that it should not be used at a station, unless in danger of running by or over something.

Int. 49. Are you governed by the shutting off steam by the engineer?

A. No, sir.

Int. 50. Do you ever apply the brake before he shuts off steam?

A. No, sir; not if I know that he has not shut it off.

Int. 51. How much quicker could you bring the train to rest with the old Springfield brake than with the Hodge brake, or with the Hodge brake than with the Springfield, at a sudden call from the engine?

A. I never have timed it, nor had any occasion for knowing as to that.

Int. 52. What is your judgment?

(Counsel for plaintiff objected.)

A. I should prefer the Hodge brake to stop a train with, on a sudden call, if I was braking against time.

Int. 53. Were you braking against time, which would you prefer under these circumstances, the old Tanner brake or the old Springfield brake?

(Counsel for plaintiff objected.)

A. The old Springfield brake.

CHARLES HARADON.

Deposition of James Lyon.

Int. 1. Please state your name, age, residence, and occupation?

1958 A. My name is James Lyon; age, 58; residence, No. 658 Broadway, Albany; occupation, brakeman on the Boston & Albany Railroad.

Int. 2. How long have you been brakeman on that road?

A. Twenty-five years come September 13th.

Int. 3. On what train are you brakeman?

A. I am now braking on M'r Marsh's train, formerly run by M'r Chapin.

Int. 4. Who hauls that train as engineer from Albany?

A. Cornelius Teeling.

Int. 5. Does he take out the same train every day, or a different train every other day?

A. A different train every other day.

Int. 6. What brakes do you have on these trains?

A. One day we have what is called the Hodge brake; and the next day we have a brake—I don't know what name you would give it, but it is a different brake.

Int. 7. What do you know about it?

A. It has two chains winding on each brake-staff.

Int. 8. How long has this brake been on that train, with two chains winding on each brake-staff?

A. Well, I don't know but you have got me now.

Int. 9. About how long?

A. I should think, about six months; perhaps longer than that.

Int. 10. Have you operated it all that time?

A. Yes, sir.

Int. 11. On what part of the train?

A. On the hind end of the train—between the two last cars.

Int. 12. What numbers are the cars that you operate it on?

A. No. 123 and No. 124.

Int. 13. What can you say of the operation of the two-chain brake, compared with the Hodge brake, which is attached to the train running on alternate days?

A. Well, sir, I cannot see any difference in stopping the train, between one and the other. I do not know that I work any harder with one than the other.

1959 Cross-examined by M'r Cozzens:

Cr.-int. 1. One is just as good as the other?

A. We stop the train just as easy. I am sure I don't work any harder with one than with the other. I have sometimes thought I had a little the easiest job when I had the two-chain brake on.

JAMES LYON.

DEPOSITIONS OF JOHN MULLIGAN, HENRY H. SNOW, WILSON EDDY AND EMERY STEBBINS.

Deposition of John Mulligan.

My name is John Mulligan; age, forty-two; residence, Springfield, Mass.; and I am now master mechanic of Connecticut River Railroad. I commenced work for the Western Railroad in November, 1842, as machinist. About the year 1843 or 1844—I can't tell which of these years—the Western Railroad run crate baggage cars; they were platform cars with small cars on them, which could be run off and run on to the boat in crossing the river at Albany; that is what they were designed for. In consequence of a brake-chain breaking, one of these cars run off the dock at Albany. M'r Ephraim Harris was then foreman in the Western Railroad blacksmith shop at Springfield. He then went to work and got up a brake like the one shown in the model now present, and "Model A, E. Merwin, U. S. C." In the old crate-car brake, the chain broke, and, in consequence, the car run off the dock. M'r Harris went to work and got up this brake, so that it would brake on both trucks from either end of the car. That brake was in use so long as the cars were in use as crate cars. There were two of them that I know of. This new car brake was applied by M'r Harris, as above stated, in the year 1843 or 1844. They went to work right along and altered the tenders to the locomotives on the Western Railroad, and applied 1960 to them the same kind of brake as the one put on the crate-cars by M'r Harris. On the tenders, they used but one chain, and connected the rod from the lever in the hind truck to the lever in the forward truck. There was but one chain from the windlass to the upper end of the truck-lever nearest the windlass; and from the upper end of this lever a rod ran to the upper end of the lever in the truck at the other end of the tender. And the same brake is in use, at the present time, on the tenders of the Western Railroad, and has been in use since then to the present time.

Cross-examination by M'r Thomas Sayles, the complainant:

I understood, at the time this brake was got up by M'r Harris, that it was for the purpose, that in case one chain broke, they would have another brake to hold on by.

I never heard any complaint of this brake not working equally on both trucks. There might have been; I never heard of any. I understood that it answered the purpose for which it was designed at the time.

I do not know about the proportions of the model produced; but I should say that the principle is the same all through.

I do not know how long the brake was used on those crate cars; whether one, two, or five years.

The brake on the tenders operated only from one end; they could have been operated from the other end by the same apparatus duplicated; that is, by adding other levers, as seen in the model. I never operated the brakes as a brakeman.

Direct examination resumed:

I mean, by adding other levers and connecting them with a windlass at the opposite end of the tender, the same as at the forward end, it would then be like the model present, and could be operated from either end of the tender, and would apply the brakes simultaneously on both trucks, when properly adjusted. The brake would be properly adjusted by "turn-buckles," as seen in the model, between the trucks, under the car body.

JOHN MULLIGAN.

1961 *Deposition of Henry H. Snow.*

My name is Henry H. Snow; age, forty-three; residence, Springfield, Mass.; and I am a locomotive engineer on the Connecticut River Railroad. I went into the employ of the Western Railroad in 1843, I think. I had charge of the brakes and running-gear of the cars of this road, generally—to look them over, and see that they were in order for running. I knew M'r Ephraim Harris when I went into the employ of the Western Railroad. M'r Harris was foreman of their blacksmith shop. I went there in the spring, and they built two crate cars, and platforms for carrying them on. One was built that summer, and the other afterwards; whether the next winter or the summer after, I can't say. When the cars were built and sent out, they had what we called double brakes. You could stand at either end of the car, and bring the brakes on to both trucks at the same time. I have looked at model now produced, marked, "Model A, E. Merwin, U. S. C.," and think it is a correct representation of the brakes applied by M'r Harris.

I had charge of the cars with these brakes on, for one summer certain; and, I think, two. They were still on the cars when I left the charge of them, and went to work in the carpenter shop of the Western road. I did not work these brakes on the road; I only worked them when I repaired them. We used to have to take up these connecting-rods with a swivel, or turn-buckle, once in a while, so as to equalize the lengths of the chains and rods running from the windlasses to the two trucks.

I don't know that I saw the brakes used more than what I used them myself.

Int. Whether or not you heard any complaint as to the working of the brake?

(Objected to by the complainant.)

A. I never did that I know of.

1962 Cross-examination by M'r Sayles:

I can't swear that the model entire is correct in all its proportions, but the principle of the thing is there.

Direct examination resumed:

By the principle of the thing I mean the brakes as they are connected and operated in model A.

Cross-examination resumed:

I mean in the last answer the general arrangement of the brake, without reference to the proportions of the brake.

HENRY H. SNOW.

Deposition of Wilson Eddy.

My name is Wilson Eddy; age, forty-nine; residence, Springfield, Mass.; and I am master mechanic of the Western Railroad, and have been connected with that road as foreman of the shop and master mechanic for the last twenty-two years. In December, 1840, we had a severe accident here in Springfield, owing to the deficiency of brakes, by an engine and train coming down this grade. The engine and train were badly smashed up, and four men lost their lives. When this engine and tender were repaired, and before it was put upon the road again, there were brakes put upon both trucks of the tender. They are operated both from one windlass by a connecting-rod running from the top of the lever in the first truck to the top of the lever in the rear truck. The lever in the first truck was operated by a windlass the same as the single brake, and the same as if the rear truck had not been connected with it. This tender went out of the shop in the spring of 1841, in April, I think. M'r Ephraim Harris got up this brake and applied it to the tender. This brake has been used from that time constantly on the tenders of this road, and is the one now in general use on our tenders. The
1963 brake shown in the model now before the commissioner, marked "Model A, E. Merwin, U. S. C.," was got up and applied to two crate cars by M'r Harris in 1842 or 1843, according to my best recollection. It was in use on those cars as long as the cars were in use, which was some two or three years; I can't recollect the time exactly. When the cars went out of use, the necessity of the double brake went out with them. I understand that this brake applies the power of the brakeman simultaneously to the brakes of both trucks, and at either end of the car.

Cross-examination by M'r Thomas Sayles, the complainant:

I should think that the brake shown in Model A did not apply the brakes equally when on a curve and on a straight line; but it will do so as nearly as a single brake.

I mean to say that this model is the same in all its essential parts as the one applied to the crate cars. I would not say positively that these levers were not in a little different position; and I am inclined to think that the truck levers were between the windlasses and the outer or front ends of the truck-frame. I should not think the crate cars were used when the river at Albany was frozen over. I can't say that I ever worked these brakes myself.

Direct examination resumed:

I know that the Springfield brake as shown in Model A was essentially the same as the one put on the express-line cars running from Boston to New York. I recollect that there was but one chain around the windlass, and that the lever of the truck at the other end of the car was connected the same as I have described in the tenders. The car was broke by the same apparatus from either end of the car.

Cross-examination:

This brake was sometime after taken off the express-line cars, and the Hodge brake was put back. I can't tell how long this brake was on. I do not know why this change was made.

* * * * * * *

WILSON EDDY.

1964 *Deposition of Wilson Eddy.*

Int. 1. Please state your name, age, residence, and occupation.

A. My name is Wilson Eddy; my age is fifty-nine years; residence, Springfield; occupation, master mechanic on the Boston and Albany Railroad.

Int. 2. How long have you been connected with the Western Railroad, and the Boston and Albany Railroad?

A. Thirty-two years, come October.

Int. 3. What positions have you occupied during that time?

A. For the first ten years, as foreman in the locomotive department; since that time, as master mechanic.

Int. 4. Were you a witness in the case of Henry Tanner against the New York and Erie Railroad, which case was tried at Albany a number of years ago? If so, state when.

A. I was a witness; I think somewhere about 1854, to the best of my recollection.

Int. 5. Did you produce a model at that time illustrative of the application of the old Springfield brake to a car?

A. I did.

Q. Have you been examined in this case before; if so, about when?

A. I should think, according to the best of my recollection, about 1862.

Int. 7. When called upon for information in reference to the use of the old Springfield brake on the Western road, did you furnish to the person calling upon you for such information a model the same as you exhibited to the court at Albany?

A. I think I furnished the same identical model to M'r Whipple.

Int. 8. Did you give evidence on the model as then produced, marked "Model A, E. Merwin, U. S. C.," in this case in 1862?

A. I think it was the same.

1965 Int. 9. You did give evidence on that?

A. I did give evidence.

Int. 10. I will here state that the model there produced was burned in the conflagration at Chicago last October, and hence the defendants have been obliged to produce a model like the one burned. Will you please now look at the model marked "Model A. E. Merwin, U. S. C." and state whether the model as to the representation of the brake is the same as the model which was burned?

A. The model, so far as the representation of the brake is concerned, I should think is the same. I can't see that there is any difference.

Int. 11. In your deposition taken in this case in September, 1862, you say, "In December, 1840, we had a severe accident here in Springfield, owing to the deficiency of brakes, by an engine and train coming down this grade. The engine and train were badly smashed, and four men lost their lives. When this engine and tender was repaired, and before it was put upon the road again, there were brakes put upon both trucks of the tender." Will you please look at "Defendants' Exhibit, old Springfield tender brake," and state whether that is a representation of the brake as applied to the tender of the engine referred to in the above quotation?

A. I should think it was. I don't see any reason why it is not. I cannot state positively as to the relative position of those levers—whether one of them was placed between the windlass and the truck or not.

Int. 12. Will you please state whether, in that or any other tender thereafter to which the brake was applied, the levers were applied outside the bar or inside the bar; and whatever answer you may give, please give your reason.

A. I should think like enough, from the construction of that tender, that the lever might have been between the windlass and the truck, from the fact that there was a long platform. The tender that the brake was put on was the first eight-wheel tender ever built in New England, and it was thought necessary to have a large space be-
1966 tween what we call the tank and the end of the tender, or a plat-
form extending some three or four feet, according to the best of my recollection, beyond the tank, between the tank and the foot-board of the engine, for the purpose of carrying wood and oil, boxes, and such like. That platform, extending beyond here [referring to model] and over the truck, would leave ample room for the lever to be between the end of the truck and the windlass. I should think it gave three or four feet as the length of this platform.

Int. 13. You will now state what modifications were made in those tenders thereafter, and state how you were obliged to apply the brakes in consequence of that alteration?

A. We found, when they came into use, that that room was unnecessary, and as soon as the tenders became rotten (one or two of them, according to the best of my recollection, were smashed up), we shortened the frame of the tender, and after that the levers were put over on the other side, put back of the forward end of the truck-bar. I do not say positively that the lever in the long tenders, even, was between the end of the truck and the windlass; it may have been.

Int. 14. How are the levers of the old Springfield brake now applied upon the tenders of your road?

A. They are attached to the back beam of the truck, farthest from the windlass.

Int. 15. Is the application the same as seen in "Defendants' Exhibit, old single brake?"

A. It is.

Int. 16. At how early a time did you make this change, as seen in the old single brake referred to?

A. I cannot tell.

Int. 17. According to your best recollection, at how early a time did you make the change; or, in other words, how soon after the change in the platforms of the tenders you have already spoken of?

A. If you put me on my memory, I shall have to say I don't know anything about it.

1967 Int. 18. When was the change from the lever, as seen in "Defendants' Exhibit, old Springfield tender brake," made to the way in which it is seen in "Defendants' Exhibit, old single brake?"

A. I don't undertake to tell exactly the position of these levers at any definite time. I know the fact that, from the spring of 1841 up to the present time, the brakes on all the tenders, so far as my knowledge goes, have been brakes that would brake on both trucks, the ends of the long levers connected together by a rod, and winding around one windlass, and braking on the two trucks; but when the change was made from the old tender brake exhibit to the old single brake exhibit, I cannot say.

Int. 19. Does it in any way change the character of the old Springfield brake, whether it is used as seen in "Defendants' Exhibit, old Springfield tender brake," or as used at one end of "Defendants' Exhibit, large Springfield brake, 124?"

A. So far as equalizing the power on the two trucks is concerned, it does not. The difference, as I understand it, is simply that we wind one chain round the windlass with the tender brake as applied to the tender, and two with the car-brake.

Int. 20. Does it make any change in the operation, or in the result of the operation?

A. I cannot see that it does, in any essential particular.

Int. 21. What would be necessary to make a car-brake like "Defendants' Exhibit, large Springfield brake, 124," out of the tender brake?"

A. It would require another set of levers, another windlass, and three more chains or connections.

Int. 22. Could you resolve the other end into one chain, by connecting the two levers together, and have it the same?

A. I don't see why I could not. Certainly I could.

Int. 23. Please state whether the old Springfield brake has been in use upon the tenders of the Boston and Albany Railroad, in one form and another, from the year 1841 to the present time.

A. It has, universally.

1968 Int. 24. Will you please state to what extent the old Springfield brake was applied to the cars of the Western Railroad, and when it was applied?

A. It was put on to two cars, commonly called crate-cars. The exact time I can't say.

Int. 25. About what year, to your best recollection?

A. I don't think my memory in that respect is definite enough to fix any time, or any time within a year or two.

Int. 26. What time do you think, within a year or two, it was applied?

A. I think it was between 1842 and 1844, according to the best of my recollection.

Int. 27. How long was it continued in use on said crate-cars?

A. Until they were thrown aside.

Int. 28. How long a time was that?

A. Well, my memory is not very definite on that point.

Int. 29. While they were in use on the said crate-cars, were they applied and used substantially as seen in "Defendants' Exhibit, large Springfield brake, 124?"

A. I think they were. I don't know that there was any essential difference.

Int. 30. Did they answer the purpose for which they were put upon said cars?

A. I never heard anything said to the contrary.

Cross-examined by M'r Cozzens:

Cr.-int. 1. On those crate-cars, was not the long chain uppermost?

A. I don't recollect.

Cr.-int. 2. So far as you know, it may have been, may it not?

A. I don't know anything about it, neither one way nor another.

Cr.-int. 3. It is not uppermost, is it, on the large model of the Springfield brake?

A. No, sir; it does not seem to be in the model exhibited.

Cr.-int. 4. Please state, if you can, what, upon the scale of "Model A, E. Merwin, U. S. C.", would be the length of the short chains and rods on the crate-cars, as they were run.

1969 A. I don't think I can. I have got this model; but I have not got the cars.

Cr.-int. 5. Then you think, do you, that it cannot be told, from "Model A, E. Merwin, U. S. C.", what the length of those two short chains and rods and long chains and rods in the crate-cars was?

A. I don't know how to do it.

Cr.-int. 6. Who made this present "Model A?"

A. I don't know, sir.

Cr.-int. 7. Was it made under your direction?

A. No, sir.

Cr.-int. 8. When did you first see it?

A. I don't recollect that I have ever seen it until to day.

Cr.-int. 9. Then it is mere memory with you, is it, as to whether it is a correct copy of the model which was burned?

A. How else should I know it?

Cr.-int. 10. I don't say that you should. I only want to know whether that is the way you get at it.

A. I don't know it any other way, only from memory. I have no data or dimensions to go by. That model differs, in some slight respects, from the other model, according to the best of my memory; but so far as it illustrates the brake, I cannot see any difference.

Cr.-int. 11. When the lever on the forward truck in the Springfield tender brake was placed upon the inside of the brake-bar, what would be the distance from the centre of the top of that lever to the centre of the windlass?

A. I don't know.

Cr.-int. 12. Can you tell anything about it?

A. I say to you that I don't know.

Cr.-int. 13. How far back from the front end of the tender was the windlass placed in those old tenders you have spoken of?

A. According to the best of my recollection, it was placed very near the front end, right at the corner.

Cr.-int. 14. In the ordinary running of trains is the brake on the tender used much?

1970 A. In the ordinary running of passenger-trains I think it is not used much. In the running of freight-trains it is used occasionally, when they want to stop sooner than they think the brakemen will stop them. In switching freight-trains it is used very generally.

Cr.-int. 15. You have said that, so far as equalizing the power on the brakes was concerned, you saw no difference between the arrangement of the old Springfield tender-brake and the arrangement of the Springfield brake at one end in "Defendants' Exhibit, large Springfield brake, 124." Suppose, in a brake arranged like said "Defendants' Exhibit, large Springfield brake, 124," one of the two chains should catch on the windlass shaft, so as to wind spirally around the staff, while the other chain wound straight around the shaft, do you think that then the brake would pull equally on both trucks?

A. Am I put here as an expert, or to tell what I know?

Cr.-int. 16. It is not for me to say. I want you to answer it to the best of your ability. You may answer it as an expert, or from what you know; I don't care. I only want you to answer it.

A. If I am allowed to say what I think, I think it is begging the question. The staff-rod comes through somewhere. It is a rod, not a chain——

Cr.-int. 17. Look at it there (in "Defendants' Exhibit, large Springfield brake, 124"); that is all I am asking you about.

A. Well, there is a rod comes up to a certain length, and that rod is supported there; and I do not see that a long rod and chain attached to it would be any more likely to wind spirally on a windlass than the short rod and chain.

Cr.-int. 18. Question repeated.

A. If one chain does wind spirally around the windlass and the other chain does not, why, it will pull unequally.

Cr.-int. 19. Previous to the putting upon the two crate cars, of which you have spoken, of what has been called the old Springfield brake, what kind of brakes were used on the cars of the Western Railroad, now the Boston and Albany Railroad?

A. I know of none being in use except what is termed the single brake.

1971 Cr.-int. 20. You are aware, I suppose, that the form of double-acting brake at present in use, on what is now the Boston and Albany Railroad, is the Hodge brake?

A. Yes, sir.

Cr.-int. 21. Have you any knowledge of any attempts made at any time on the Western Railroad to get up double-acting brakes, between the time when the Springfield brake was put on these two crate-cars and the time when the Hodge brake was introduced on said railroad?

A. I don't know that I have, on this road in particular.

Cr.-int. 22. What do you mean by "this road in particular"—the Western road, part of it, or what?

A. No, sir. I mean that a man by the name of Nichols, to the best of my recollection, worked on a brake for considerable time, and got up a brake and put it on the Hartford and New Haven road. At least, I so understand it; I think so.

Cr.-int. 23. Was Nichols in the employ of the Western Railroad before going on the Hartford and New Haven Railroad?

A. He was.

Cr.-int. 24. Do you know about how long?

A. Well, several years; I can't tell.

Cr.-int. 25. Can you give any idea, without being very accurate about it, about from what year to what year?

A. No, sir; I don't know as I should want to state.

Cr.-int. 26. Can you say previous to what year?

A. No, sir; I don't know when he came, nor exactly when he went away, according to the best of my recollection.

Cr.-int. 27. Do you know of a brake which had in it a chain which ran from one end of the car to the other, around pulleys, and was put on passenger-cars of the Western road?

A. I do, sir.

Cr.-int. 28. Was that a brake which was designed to operate on all the wheels of the car from either end of the car?

A. Yes, sir.

Cr.-int. 29. About what time, as nearly as you recollect, was that brake tried on the Western Railroad?

1972 A. Well, I got the brake up myself, and put it on. It was, say, twelve or fifteen years ago. I don't want to fix it very definitely.

Cr.-int. 30. Was it before the Hodge brake was introduced on the Western road?

A. No, sir; I think it was before they bought the Hodge brake. It was not used much of any, if it was any, before this brake was got up. My intention was, of course, to obviate the necessity of buying the Hodge brake.

Cr.-int. 31. Did you apply for a patent for this chain-brake?

A. I did.

Cr.-int. 32. About how soon after you got it up did you apply?

A. I should say a few months.

Cr.-int. 33. Will you please bring in the patent this afternoon, that we may see the way the Patent Office has entitled the invention, so that we can know how to send for this date?

A. I will.

Cr.-int. 34. Did you not get up another brake, intended to act on both ends of the car from either end of the car?

A. M'r Emery Stebbins and myself did.

Cr.-int. 35. When did you get that up?

A. I can't fix the time; but it was previous to the chain-brake, according to the best of my recollection.

Cr.-int. 36. Did you apply for a patent for that?

A. We either applied for a patent or filed a caveat. I think we only filed a caveat.

Cr.-int. 37. What was the distinguishing feature of this last-mentioned double-acting brake?

A. There were two pulleys fixed in a frame, and that frame was allowed to slide in the centre of the car, fore and aft, and a chain went around each of these pulleys, so that when you pulled on one you pulled on the other, and consequently pulled on the brake operating on the opposite truck.

Cr.-int. 38. Was this sliding-frame brake designed to operate as an equivalent for the Hodge equalizing levers?

A. It was.

1973 Cr.-int. 39. Was said sliding-frame brake put upon one or more cars on the Western Railroad? If so, how many cars?

A. On one or two.

Cr.-int. 40. About how long was it continued in use on these cars?

A. I have no recollection.

Cr.-int. 41. Was it some little time?

A. Some little time, I should think; might be a year; might be more, might be less; might be, I should say, a year or two.

Cr.-int. 42. Down to about what year were single-acting brakes, operating upon only one truck, continued in use upon the passenger-cars of the Western Railroad?

A. I know they were continued here longer than upon almost any other road. I don't recollect the time when we bought the Hodge brake; but immediately on purchasing the right to use that brake we shifted from the single to the Hodge brake. I should think it was after I was called upon to testify in this same case in 1862. I should think it was as late as 1863 or '64.

Cr.-int. 43. After using the Springfield brake, as you have stated, on the two crate-cars, was it used on any other cars of the Western Railroad?

A. I can't tell you.

Redirect:

Int. 31. Please state what your primary object was in getting up the double-pulley brake, such as you applied for a patent for?

A. The object was to get a brake that would brake equally on all the eight wheels of a car, and have as good a brake as was in use, and obviate the necessity of the company's purchasing the right to use from other parties.

Int. 32. The question may arise why you attempted to get up another brake, such as the pulley-brake to which you have referred? If so, knowing as you did of the existence of the old Springfield brake, why not apply the old Springfield brake to a car, instead of attempting to get up one?

A. The old Springfield brake does not brake alike on all the wheels. My object was to get up one that did.

1974 Int. 33. And to obviate the purchase of patents?

A. Why, yes; but we were not obliged to buy the old Springfield brake. The object was to get up a brake that would brake on all the wheels alike, and have a good brake, as good as there was in use.

Recross:

Cr.-int. 44. Do you mean the Hodge patent, for one?

A. Yes, sir.

Cr.-int. 45. Does the Hodge brake brake alike on all the wheels?

A. No, sir.

Redirect:

Int. 34. You have stated that you got up a double brake called the pulley brake, about the year 1857 or 1858, and that a patent was obtained for the same. Was said brake, in your judgment, a practical operative brake?

A. It was.

Int. 35. If so, please state why the company did not adopt the same, in preference to some other double brake.

A. The company had purchased no right to use the Hodge, Stevens, or Tanner brake, and we were satisfied that we should be called upon for infringing perhaps the Hodge and Stevens brake.

Int. 36. To what extent was this pulley-brake used?

A. It was used on two cars, I think, for one or two years.

Int. 37. When the company finally decided to adopt the double brake on their main line, between Albany and Worcester, what patent did they finally decide to purchase and adopt?

A. I think the Hodge.

Int. 38. At what time did Ephraim Harris, who formerly had charge of the blacksmith shop of the Western Railroad, leave the service of said railroad?

A. I can't fix the date very definitely; but I think somewhere from 1851 to 1853.

Int. 39. Under what circumstances did said Harris leave the employ of the company now the Boston and Albany Railroad Company?

A. He was discharged.

1975 Int. 40. Why discharged?

A. For taking money from workmen, for giving them a situation in the shop, and for exacting from them money to retain their situation after he had given it to them.

Recross:

Cr.-int. 46. Did Hodge sue the Western Railroad corporation for infringing his patent, on the line cars from Boston to New York?

A. I have no positive knowledge of it; but I so understood it.

Cr.-int. 47. Were there several suits brought by Hodge for said infringement?

A. I am not positive, but think there might have been. After some difficulty about this matter, I understood they purchased the right to use the Hodge brake.

Cr.-int. 48. At folio 537, of defendants' accounting proofs, you stated that you would bring in the patent there referred to. Is said patent now present? and, if so, will you state who was the patentee named in it; what is the date of it, and what is the title of the invention given in it?

A. The patent is present. The patentee named in it is J. N. Ward, of Brooklyn, New York; the date of it is Nov. 2d, 1858, and the title of the invention given in it is "Improvement in car-brakes." The number of patent is 21996.

Cr.-int. 49. Your application was put into interference with the case of J. N. Ward, was it not?

A. It was. As the invention was the same in both cases, we abandoned our application and made arrangements with M'r Ward, whereby we obtained half of his right, and caused the patent to be issued; and that patent is the one now produced.

Cr.-int. 50. Will you please state, as near as you can, what was the length of the crate cars on which the Springfield brake was applied, on the Western Railroad, in 1843 and 1844?

A. To the best of my recollection, about 45 feet. I know they were very long cars, for the times.

Cr.-int. 51. What is the length of tenders on the Boston and Albany Railroad?

1976 A. On our first-class engines our tenders are 18 feet and 3 inches. I think these are as long as any; we have some shorter.

Cr.-int. 52. About how much do the tender bodies project beyond the trucks?

A. Say about 6 inches at the rear end, and about 12 inches at the front end.

Cr.-int. 53. Were both of the double brakes that you have referred to on pages 137 and 138 of defendants' accounting proofs hand-brakes operated from windlasses at the ends of the cars in the usual manner?

A. Yes.

Cr.-int. 54. You have spoken, in your direct examination, of Ephraim Harris being discharged from the employ of the Western Railroad. Did you discharge him yourself?

A. No, sir.

Cr.-int. 55. Do you know why he left the road, except from report?

A. I know of it from conversation with the superintendent, my own observation, and conversations with the men. I was satisfied that he was spending more money in his manner of living and incidental expenses than he was receiving as salary from the road. This last is what I refer to as my own observation.

Cr.-int. 56. You mean, I suppose, this was your judgment? You couldn't know it positively.

A. Yes; it was my judgment. I didn't know it positively.

Redirect:

Int. 41. Do you know it positively that he was discharged?

A. I know that the superintendent told me so, and that he left very suddenly. And I never heard any fault found with his work, and think it could not be on that account.

(Complainant objects to the thoughts and hearsay stated by the witness.)

I wish to further say that I found no fault with his work myself; and I should, if anybody.

1977 Int. 42. Is there any doubt in your mind that he was discharged for the reasons stated in your previous examination?

(Objected to as incompetent by the complainant.)

A. Not the slightest doubt.

Int. 43. You speak of conversations with his men; what in substance were said conversations?

(Objected to.)

A. The language I don't recollect; but the substance of their conversations was, that they had paid him money for their situations, and, to retain them, a monthly stipend.

Int. 44. Do you believe such conversations to be true?

(Objected to.)

A. I do.

WILSON EDDY.

Deposition of Emery Stebbins.

My name is Emery Stebbins; age, thirty-six; residence, Springfield, Massachusetts; and I am car-inspector on the Western Railroad, at Springfield. I have been in the employ of the road twelve years—part of the time in the wood-shop, on repairs.

I know of the use of a brake, on the cars of the Western Railroad, similar to that represented in the model now before the commissioner, marked "Model A, E. Merwin, U. S. C." We first used it on car No. 2 of the Western Railroad. It was a passenger-car. I should think it was about six years ago—about the year 1855 or 1856—that we put it on this passenger-car; and was used about two years, I think, on that car at that time. It was put on to what line cars we had soon after that —on all the cars in the express line between New York and Boston. It was put on to twenty-two or twenty-four cars, passenger and baggage, at that time. They were on about sixteen months; it was over a year, I know. 1978

All the difference between the brake exhibited in the model and the brake which was applied to those twenty-two or twenty-four cars was, that in the brakes of these cars but one chain wound round the windlass, and that chain was attached to the upper end of the lever in the first truck, and a rod attached to the same point connected it to the upper end of the lever in the second truck; and the same may be said of the attachment at the other end of the car. The reason why we put it on in this way was to get rid of the second chain, and save us the trouble of altering the windlasses; but it didn't make the brake any better.

This brake applied the brakes simultaneously to both trucks, and from either end of the car. I operated these brakes while switching the cars. I call it a good brake when in order. It was no more liable to get out of order than other brakes.

I am acquainted with the centre-lever or Tanner brake. I think you can apply the power to the trucks as well with the brake shown in Model A, as with the Tanner brake, and at either end of the car.

Cross-examination by M'r Sayles, the complainant:

I never operated the Tanner brake or the Springfield brake out on the road; no other way than switching in the yard. I know why these Springfield brakes were put on the express-line cars. When the express cars were built, the Hodge brakes were put on the cars and on to the road, and the Western Railroad did not own the right to use them; and that is the reason why the Hodge brake was ordered off, and these Springfield brakes were ordered on, and they were put on. I don't know whether Hodge commenced a suit or not. I don't know why this brake was not continued on the cars, but think some compromise was made, by which the right to run the Hodge brake over this road was obtained. The Hodge brake was put back, after the Springfield brake had been running sixteen months. The Springfield brake was 1979 abandoned, after running some sixteen months, and the Hodge brake was put back again on these twenty-two or twenty-four cars.

The levers in the express-line cars were arranged the same as in the model, except that in the express cars the short arm of the first truck-lever set on the connecting-rods of the brake operating from the other end of the car. The operation was just the same and the result was just the same.

The bottom end of the truck-lever set in a slot on the connecting rod, with a pin through it, so as to hold it permanently in its place, instead of being attached to the brake-bar. The result would be just the same in either case.

The brake we had on the car of the Western road was precisely like the one in the model. That has been removed, and the single brake put in its place. The Springfield brake was on this car two or three years. I should think it was put on the last of 1855 or the first of 1856, about that time.

Direct examination resumed:

The brake in general use now on the Western Railroad is the single brake; and always has been since the opening of the road, so far as I know.

EMERY STEBBINS.

Deposition of John Lightner.

Int. 1. What is your name, age, residence, and occupation?

A. My name is John Lightner; nearly sixty years old; reside in Roxbury, Mass.; occupation, car-builder for the Boston and Providence Railroad.

Int 2. How long have you been car-builder for the Boston and Providence Railroad?

A. I have been in their employ ever since 1834.

Int. 3. How long have you had charge of the car department of that road?

A. About 34 years.

Int. 4. What brake is in general use on the passenger-cars of the Boston and Providence road?

1980 A. At the present time, the Hodge brake.

Int. 5. What brake did you use on the passenger-cars on that road before the company adopted the Hodge brake?

A. Pretty much the Tanner brake.

Int. 6. Please look at "Exhibit, large Tanner brake, 123," and state whether you put on the Tanner brake with a centre-lever connected as this lever is connected.

A. That was generally the principle we put it on. On two or three cars I hooked the rod in, just the same as I did for Mr Sayles; but only from three to six inches, more or less.

Int. 7. Are you acquainted with what is called the old Springfield brake?

A. So far as it was put on our road.

Int. 8. When did this old Springfield brake first come to your knowledge?

A. When I was directed by you (Mr Whipple), through Mr Folsom, superintendent of the Boston and Providence Railroad, to put it on. That is the first knowledge I had of it.

Int. 9. About what time was that?

A. I can't seem to recollect exactly the time.

Int. 10. Some time last winter?

A. I think it was.

Int. 11. Did you see it first on a model or on a car?

A. I saw it first on a model.

Int. 12. Is the model here? If so, please point it out.

A. Well, that ("Exhibit A, E. Merwin, U. S. C.") seems to be the nearest like it; only the levers are differently constructed, you know. I mean the difference of construction was not in the model, but in the car to which I applied it.

Int. 13. Did you apply this brake to one or more cars on the Boston and Providence Railroad?

A. I applied it to two.

Int. 14. And in the same way as seen in the model, or in a different way? And if in a different way, explain how you applied it.

A. Well, instead of putting the short arms of the levers on the brake-bars, as seen in the model, I put the fulcrums of the levers on
1981 the bars, in the manner seen in "Defendants' Exhibit, old single brake;" and connected the same with the windlasses of the car, at either end, by two chains. By this I mean to be understood, that the connection between the windlass and the first lever ran to the inner side of the truck, and was some 14 feet long, while the long rod ran from the same windlass to the further truck, and the same mechanism was duplicated from the other end.

Int. 15. About the same time that you put the old Springfield brake on to two cars, did you apply the Tanner brake to another car?

A. Yes, sir.

Int. 16. Please name the cars on which you applied the old Springfield brake.

A. I believe they were Nos. 12 and 40, and the Tanner brake was applied to car No. 10.

Int. 17. What is the weight of the cars to which both brakes were applied?

A. Well, if I should guess (it would be a matter of guess-work), I should think they were about equal; and I should think each car would weigh about 18 tons.

Int. 18. Were the cars of the same pattern or build?

A. Yes, sir; they were of the same pattern.

Int. 19. And by whom built?

A. By Bradley.

Int. 20. Can you give us the length of the long arm of the levers, and also the short arm of the levers, in the trucks of the old Springfield brake?

A. Yes, sir; the short arm, six inches long; the long arm, two feet five inches; the fork that supports the lever, eight inches from the inside of the beam to the centre of the lever.

Int. 21. Please state, if you have it, the fulcrum in the levers applied on the Tanner brake.

A. The short arm was six inches, and the long arm was two feet four inches, and the fork eight inches.

Int. 22. What was the length of the centre-lever?

A. Four feet.

Int. 23. How were the rods running from the truck-levers to the centre-lever connected with said centre-lever, at the end or a few inches from the end?

1982 A. The first I put on the rods were connected with the outside end, the same as "Defendants' Exhibit, large Tanner brake, 123;" then they were shifted ten inches from the end of the lever, towards the centre of the same.

Int. 24. At whose request was this modification made?

A. M'r Sayles.

Int. 25. In putting on the modified Tanner brake, did M'r Sayles have everything just as he wanted it?

A. Yes, sir; to the best of my knowledge.

Int. 26. In every respect?

A. In every respect, to the best of my knowledge.

Int. 27. Was the leverage in the truck changed from what it was when you put it on in your way?

A. There was some alteration made, so as to make it conform with the Springfield brake; everything accurate, you know, as near as we could.

Int. 28. State whether the Tanner brake is in use on passenger cars on any road with which you are acquainted.

A. I know of no road with which I am acquainted that I could say.

Int. 29. What brake is in general use in New England on passenger cars?

A. The Hodge brake, in my opinion, as far as I know.

Int. 30. Who is conductor on the train on which the Springfield brakes are used?

A. M'r Lincoln.

Int. 31. And who is the brakeman?

A. M'r Rogers.

Cross-examined by M'r Sayles:

Cr.-int. 1. Were the lengths of the truck-levers and their arms alike in both cars having the Springfield brake on your road?

A. Well, I measured the levers on one of the cars with the Springfield brake, and I measured the levers of the Tanner brake, and I found there was a variation of one inch in the long arm of the levers.

Cr.-int. 2. You did measure the levers in the other car having the Springfield brake?

1983 A. No; I only measured the levers in the Tanner brake and in one of the Springfield brakes. They won't vary over an inch; I will guarantee that.

Cr.-int. 3. Why did you put the Springfield brake on differently from the model that was shown you? Was it by M'r Whipple's orders? Did you put them on the cars just as M'r Whipple directed?

A. It was put on as M'r Whipple ordered, all through.

Cr.-int. 4. Which, in your judgment, would work the best, where the short chain from the windlass to the first lever was three feet and four inches, or three feet and a half long, as shown in the "Model A, E. Merwin, U. S. C.," or where the lever is placed at the other end of the truck, as in your car, and that rod fourteen feet long?

A. In my judgment, that rod fourteen feet long would work the best.

Cr.-int. 5. In your judgment, would it be safe to run a train of passenger cars at a high rate of speed, supposing the first lever is placed outside the end of the truck, and the chain attached from the windlass to that lever, which brought the lever within fourteen inches of the windlass? Would it be safe to run a train of cars, in your judgment, with a brake arranged like that?

A. I should prefer not to have it so.

Cr.-int. 6. Would you consider it safe to run a train of passenger cars in that way; to apply the brake on a straight track, and run from straight tracks to curves, and vice versa, with a brake so arranged?

A. I am hardly prepared to answer that question. I did not expect that question was coming up, so I am hardly prepared to answer it.

Cr.-int. 7. Would you be willing to take the responsibility of arranging a train of passenger cars in that way and have it run over your road at a high rate of speed, and have the brakes applied on straight tracks, and run from straight tracks to curves, with the brakes so applied?

A. I am not prepared to answer that question.

Cr.-int. 8. Do you think that a brake arranged in that way, with a fourteen-inch chain, would swivel freely around a curve?

1984 A. Well, M'r Sayles, I have not looked into the matter. I never saw a car constructed in that way, and therefore I am not prepared to say what I should think about it.

(Plaintiff put in drawing marked "Complainant's Accounting Exhibit, No. 1, J. M. W. Y.")

Cr.-int. 9. Please look at "Complainant's Accounting Exhibit, No. 1, J. M. W. Y.," and state whether you would consider that a safe brake to put on a passenger train.

A. I have not seen any construction in that way, and I am not prepared to answer the question. I have not looked into that at all. My whole attention was paid to the way we constructed them.

Cr.-int. 10. Those short chains are represented on the drawing to be 14 inches long. If that lever at the end of the 14-inch chain was placed inside the truck, so as to make a chain three feet and four inches, or three feet and a half long, do you think it would work better than with a chain fourteen inches long?

A. Why, it would give it little more motion.

Cr.-int. 11. Give it a better chance to turn the curves, do you mean?

A. Well, it would give it a little more motion, I admit.

Cr.-int. 12. Do you think one three feet and four inches would work better than one fourteen inches long?

A. I think it would give it some more motion. I can't tell. I would prefer to see one before I give any definite opinion about it. I have never seen one; therefore I am a little particular about it. If that is hooked back fourteen feet from the windlass, as on our cars, I should not be a bit afraid of it.

Cr.-int. 13. You mean, when you say it would give it more motion, that it would give more freedom to trucks in swivelling on the curves?

A. Yes; I mean there isn't enough to make any defect worth speaking of on our road, the way we construct it, it is such a trifle. I don't know what it is on other roads. I admit there is a variation there,
1985 even in ours. When you set the brakes on a curve, and run on to a straight track, I admit there is a variation; but it never seemed to have any effect on the brakes I had on, to my knowledge.

Cr.-int. 14. Did you ever apply them on curves and straight tracks?

A. No, sir.

Cr.-int. 15. What brake do you consider the best brake now in use?

A. I consider the Hodge hand-brake the best in use.

Cr.-int. 16. Are you acquainted with the Stevens brake?

A. Somewhat acquainted with it.

Cr.-int. 17. Do you think the Hodge very much better than the Stevens?

A. I do, sir, for railroad purposes.

Cr.-int. 18. Are you acquainted with the wearing of the brake-shoes on cars?

A. Some acquainted with it.

Cr.-int. 19. Is it a common thing for one brake-shoe to wear out a great deal faster than another?

A. Yes, sir.

Cr.-int. 20. What difference is there in the wearing of shoes generally on cars?

A. It depends a good deal upon the metal. Sometimes we have softer metal than at others, and that makes a difference. If the metal was all alike, the wear would be where the most power is applied.

Cr.-int. 21. How is it on your road, as a general thing?

A. As a general thing, it is where the most power is applied; but we find sometimes the shoe wears a little faster, and then again we have had metal that was hard; it don't make any difference, you know.

Cr.-int. 22. Do some shoes often, or occasionally, wear two or three times as long as others of the same character?

A. Well, all I could say about that is this, that there are times when one shoe will last a great deal longer than another; but how much, I can't say. That is all owing to the hardness of the metal. We have had a pair of shoes on one truck, and one would wear a great deal faster than the other. One would wear out where the other
1986 would hardly wear any, on account of the difference in the temper of the metal.

Redirect:

Int. 32. Please look at "Defendants' Exhibit, Large Springfield brake 124." and then at "Complainant's Exhibit, No. 1, J. M. W. Y.," and state whether the connections with the windlass, as represented in both exhibits, are substantially different or substantially the same.

A. Well, according to my judgment, they appear to be substantially the same.

Recross:

Cr.-int. 23. Is the short chain or connection from the windlass to the first lever longer than represented on the drawing?

A. I should think that (in old Springfield brake) was longer than 14 inches.

(It is agreed that the "Complainant's Accounting Exhibit, No. 2, J. M. W. Y.," is a correct representation of the mode in which the Springfield brake was applied to the two cars, No. 12 and No. 40, on the Boston and Providence Railroad.)

JOHN LIGHTNER.

Deposition of G. F. Lincoln.

Int. 1. What is your name, age, residence, and occupation?

A. My name is George F. Lincoln; age, 34; occupation, conductor on the Boston and Providence Railroad.

Int. 2. How long have you been so occupied?

A. Six years.

Int. 3. On what train are you conductor on the Boston and Providence Railroad?

A. On the 10.30 a. m. train from Boston.

Int. 4. How many cars compose the train?

A. Four passenger and one baggage car.

Int. 5. What brakes are in general use on the Boston and Providence Railroad?

1987 A. The Hodge brake.

Int. 6. What brakes are in use on this train which you run?

A. On two cars we have the Springfield brake; on one car the Tanner brake; and on the other two the Hodge brake—all in the same train.

Int. 7. How long has the old Springfield brake been in use, and how long the Tanner brake, on your train?

A. Some time last December the Springfield brake was put on; the Tanner brake, I think, a few days after.

Int. 8. On how many cars is the old Springfield brake?

A. Two cars.

Int. 9. What are the numbers of the cars?

A. No. 12 and No. 40.

Int. 10. On how many cars is the Tanner brake?

A. One—No. 10.

Int. 11. Has there been any modification of the Tanner brake since it was first applied?

A. There has.

Int. 12. By whose request was the modification made?

A. M'r Sayles', I believe.

Int. 13. How has the Tanner brake worked since the modification by M'r Sayles?

A. Very well.

Int. 14. Better than when put on by M'r Lightner the first time?

A. I think it has.

Int. 15. I wish to institute a comparison between the working of the old Springfield brake and the Tanner brake, as modified by M'r Sayles. Will you please do so, and state the result of such comparison?

A. You can brake a train up quicker, I think—I know so—with the Springfield brake, than you can with the Tanner brake. It takes the slack quicker; there is not so much slack.

Int. 16. At the Mansfield station on your line, on what car and brake do you allow the brakeman to bring the train to rest, after the engine is cut loose from the train?

A. On No. 10, No. 12, and No. 40; we change them alternately.

1988 Int. 17. That is, you use either the Tanner or the Springfield brake?

A. Yes, sir.

Int. 18. Is the control of the train left entirely to one or the other of these brakes at this station?

A. We have a brakeman at the rear end of the train, should anything happen; but, as a general thing, one man holds it.

Int. 19. What is the object of cutting off the engine at that place?

A. At Mansfield, we take on the Taunton and New Bedford train. We run down, and back on to the New Bedford track, and take that train on; and then go down on to the Boston and Providence track, and back down and take on our train. We take water there, and the object is to save time.

Int. 20. Then both brakes are deemed by you to be reliable in this particular place?

A. Well, we have depended on them.

Int. 21. Have you any preference as to which brake is used at the head of the train, after the engine is cut loose, on the score of certainty of control and quickness of action?

A. Yes, sir; I should prefer the Springfield brake which we have been using.

Int. 22. For what reason?

A. Well, as I said before, it takes hold quicker, and I think I can hold the train better with it.

Int. 23. In view of your responsibility as conductor of the train, do you or not deem the old Springfield brake, properly taken care of, a safe brake?

A. I do, so far as I have knowledge.

Int. 24. Have you operated this brake yourself, both on curves and a straight track, and while the car was running under the brakes from a straight track to a curve, and vice versa?

A. I have.

Int. 25. With what result?

A. I have not found any difference yet between the Springfield brake and the others, in running from a straight track to a curve.

1989 Int. 26. Have you discovered any difficulty in applying the Tanner brake, in running from a straight track to a curve, or from a curve to a straight track?

A. No, sir.

Int. 27. Has there been any complaint from the brakemen that the chains which wind upon the brake-shaft of the Springfield brake override each other, and thus destroy the effect of the brake on the wheels?

A. No, sir.

Int. 28. Has any accident happened on your train since the old Springfield brake was applied, in consequence of defective or inoperative brakes?

A. No, sir; not to my knowledge.

Int. 29. What is the average speed of your train?

A. About twenty-five miles an hour.

Cross-examined by S. D. Cozzens:

Cr.-int. 1. You say you think you can brake quicker with the old

Springfield brake than with the Tanner. Do you think there is more power in the Springfield brake, as arranged on the cars of the Boston and Providence road, than in the Tanner brake on that road?

A. Yes, sir.

Cr.-int. 2. It is a pretty good brake, is it, the Springfield brake?

A. I consider it a very good brake; a safe brake.

G. F. LINCOLN.

Deposition of H. M. Rogers.

Int. 1. What is your name, age, residence, and occupation?

A. H. M. Rogers; age, 31; residence, Boston; occupation, brakeman on the Boston and Providence Railroad.

Int. 2. How long have you been brakeman on the Boston and Providence Railroad?

A. I have been braking on that read two years and a half, and on the Albany a year.

1990 Int. 3. What train do you run on as brakeman?

A. The 10.30 from Boston and 4.15 from Providence.

Int. 4. The same as is run by M'r Lincoln, as conductor?

A. Yes, sir.

Int. 5. What brakes are in use on the train which you run as brakeman?

A. The Hodge brake, the Springfield brake, and the Tanner brake.

Int. 6. You speak of the Springfield brake and the Tanner brake; how long have these brakes been in use on this train?

A. They were put on in December, if I recollect aright.

Int. 7. Has there been any modification in the Tanner brake since it was put on the first time?

A. There has.

Int. 8. At whose request?

A. M'r Sayles'.

Int. 9. How has the Tanner brake worked since the modification by M'r Sayles?

A. It has worked better than it did the first time.

Int. 10. How, as a general thing, has the old Springfield brake worked since it was put on?

A. Well, it has worked very well.

Int. 11. To which do you give the preference, if indeed you have any?

A. The Springfield brake.

Int. 12. Please give your reasons for this preference?

A. Because it will hold better.

Int. 13. On what cars of the Boston and Providence road is the old Springfield brake used?

A. On No. 12 and No. 40.

Int. 14. And on what car the Tanner brake?

A. No. 10.

Int. 15. Which of these brakes have you run in the rear of the train, first and last?

A. We have run all of them, not giving one the preference more than the other.

Int. 16. With which brake can you slide the wheels the quickest and easiest?

1991 A. There is only one brake that I have ever slid the wheels with on that train, and that is the Springfield. I don't say anything about the Hodge brake.

Int. 17. When the engine is cut off to receive the Taunton and New Bedford train, on what car and what brake do you rely to stop the whole train at Mansfield?

A. They have used the three—Nos. 12, 40, and 10.

Int. 18. That is, both the Springfield and Tanner brake?

A. Both the Springfield and Tanner brake.

Int. 19. Which brake did you use the last time you ran a train over the road, switching into Mansfield?

A. No. 12, last Tuesday night.

Int. 20. Have you any particular choice whether you use No. 12, Springfield, or No. 10, Tanner?

A. Yes, sir; I have a preference.

Int. 21. Why?

A. As I said before, because the Springfield will hold better.

Int. 22. Have you had any trouble with the chains on the old Springfield brake overriding each other, or toggling upon each other, and thus destroying the efficiency of the brake?

A. No, sir.

Int. 23. Have you observed the operation of this brake when the train is running under the brakes, from a straight track on to a curve, or from a curve on to a straight track; if you say you have, state your observation?

A. I have seen no difference whatever. If there is any difference, it is so slight I cannot perceive it.

Int. 24. Please state whether, in your judgment, the old Springfield brake, properly adjusted, and the wear of the shoes taken up, is a safe brake to be used in stopping a railroad train?

A. There is no doubt in my mind that it is, so far as I have used the brake.

Cross-examined by M'r Cozzens:

Cr.-int. 1. When did you first know what the Tanner brake was?

1992 A. When it was put on by M'r Sayles.

Cr.-int. 2. That is the first you had ever heard of it?

A. That is the first I had ever heard of it.

Cr.-int. 3. What has led you to take notice as to the comparative working of the Springfield and Tanner brakes on this train?

A. I don't know but you might think it a little mite saucy for me to answer that, but I should tell you common sense—working the brake. The Springfield brake would hold so much better; the Tanner brake would not hold at all. The way it was first put on, I could not stop the train with it.

Cr.-int. 4. Do you know who put it on in that way at first?

A. I can't say who put it on first; but I have understood M'r Lightner did it.

Cr.-int. 5. He is car master of the road, is he?

A. Yes, sir.

Cr.-int. 6. Has anybody connected with the road directed or requested you to notice the relative manner in which the brakes work?

A. No, sir.

Cr.-int. 7. When did you first know what the Springfield brake was

A. When it was first put in the train last winter.

Cr.-int. 8. You had never heard of that brake before, had you?

A. No, sir.

Cr.-int. 9. Who first told you it was the Springfield brake?

A. M'r Whipple.

Cr.-int. 10. How long was that after it had been put on the train?

A. I don't know as I could say; soon after it.

Cr.-int. 11. Did M'r Whipple tell you whether it was a good brake or not?

A. He did not.

Cr.-int. 12. What did he say about it?

1993 A. He said there was a brake on for me to try, and he wanted me to use it. That was all there was said about it. At first, he said nothing. When the brake was first put on I knew nothing about what it was put on for, until we used it; and it was some week or fortnight after that before I knew what it was. It was put on there to use and see how it would work.

Cr.-int. 13. Do you know what the company wanted to see how it would work for?

A. I did not, at the time.

Cr.-int. 14. Do you now?

A. No; I don't know as I do.

Cr.-int. 15. What do you suppose it was for?

A. I can't say, sir.

Cr.-int. 16. What did you mean when you said that you did not at the time know?

A. Well, I didn't exactly mean that at the time. I said I knew nothing what it was put on for, and I don't. I have merely heard it talked around outside—that is all. I paid no attention to it, whatever.

Cr.-int. 17. Did you ever hear there was any suit about the Tanner brake?

A. I have only heard it talked around. No, I didn't.

Cr.-int. 18. You just said you heard it talked round. What do you mean by that?

A. I merely heard it talked round. No one came to me that I supposed knew any more about it than I did; merely the men round—that was all.

Cr.-int. 19. You have heard there was a suit about the Tanner brake?

A. Yes, sir.

Cr.-int. 20. How soon after the Springfield and Tanner brakes were put on this train, did you first hear there was a suit about the Tanner brake?

A. I can't tell you.

Cr.-int. 21. A week, a month, three months, or what?

A. Probably two or three months.

Cr.-int. 22. Of the two cars which had the Springfield brake on, which worked the best?

A. I saw no difference, sir, whatever, in them.

1994 Cr.-int. 23. Do you think there is more power in the Springfield brake, as arranged on the Boston and Providence cars, than in the Tanner brake, as arranged there?

A. I do, sir.

Redirect:

Int. 25. Why do you think there is more power in the Springfield brake than in the Tanner brake?

A. Well, all I can say is, as I said before, it will hold better.

H. M. ROGERS.

Deposition of Benj. C. Read.

Int. 1. What is your name, age, residence, and occupation?

A. Benj. C. Read; age, 49; residence, Bristol Co., Mass.; occupation, car-builder on the Boston, Lowell and Nashua Railroad.

Int. 2. Do you have charge of the car department of that road?

A. I do at present.

Int. 3. How long have you had such charge?

A. The last fifteen years.

Int. 4. What brakes are used on the passenger cars of the Boston and Lowell road?

A. The Hodge.

Int. 5. Are you acquainted with what is called the old Springfield brake?

A. No further than what we applied it there in this present experiment.

Int. 6. To what extent did you apply it—to how many cars?

A. Four.

Int. 7. In what train are the cars run to which said brake was applied?

A. Lowell accommodation.

Int. 8. About what time did you make the application of the Springfield brake to the four cars, or to the whole train composed of four cars?

1995 A. In the month of January, 1872.

Int. 9. Who is conductor and who brakemen on that train?

A. M'r Blood is conductor, and M'r Emerson and M'r Wing are brakemen.

Int. 10. What is your estimate as to the weight of the cars composing this train?

A. The passenger cars weigh eighteen tons; the baggage car is not so heavy.

Int. 11. These four cars consist of what kind of cars?

A. Two first-class, a smoking-car, and baggage-car.

Int. 12. What would you estimate the weight of the four cars?

A. The smoking-car and the two first class cars would weigh eighteen tons each; the baggage-car would weigh about twelve tons.

Int. 13. Making in all, how many tons?

A. Sixty-six tons.

Int. 14. What would you estimate the weight of the engine and tender, which hauls this train?

A. It is about a 25-ton engine.

Int. 15. Making the whole weight of the train, what?

A. I am not positive whether the tender would be included in the weight of the engine or not. I know they are equipped ready for service when we weigh them. I should say the train would weigh, altogether, 100 tons at least.

Int. 16. In applying the Springfield brake to a whole train of cars, what modifications, if any, did you make, compared with "Defendants' Exhibit, large Springfield brake, 124?"

A. Well, we modified the levers by putting them inside of the truck, inside of the bar; and put the fulcrum on the bar opposite to the front lever in the exhibit, on the farthest end of the truck from the windlass, the same as in "Exhibit, old single brake."

Int. 17. Where did you put the other lever?

A. On the opposite end of the same truck.

Int. 18. And applied the levers in the same way on the other truck?

1996 A. The same on the other truck.

Int. 19. Then how did you connect these levers with the windlass or brake-shaft?

A. With two rods and two chains—just the same as in this model, substantially.

Int. 20. Please state whether, in your judgment, such modification as you have described in any way changes the character of the old Springfield brake?

A. I should think not. Whether the fulcrum was on the rod or on the bar, I should say the character of it was the same.

Int. 21. Please look at "Defendants' Exhibit, old Springfield tender-brake," and state whether, had you put the brake on as therein represented, it would have changed its character?

A. No; it is the same thing. It is a straight connection from one truck to the other. It would not change the character.

Int. 22. What further is necessary to make the said exhibit "Springfield tender-brake" a passenger-car brake?

A. To duplicate the same brake on the windlass at the other end of the car.

Int. 23. Does the position of the levers upon the brake-bars, or dispensing with one of the chains upon the windlass-staff, in any way change the character of the old Springfield brake? Whatever your answer may be, give the reason for it.

A. I should think it would not. With two chains, the same power is applied to the two points as it would be with one chain. There would be no difference, whether it was wound up with two chains or with one chain.

Int. 24. Please look at "Model A, E. Merwin, U. S. C." What brake do you call that?

A. This is the Springfield—the old brake.

Int. 25. Wherein does it differ from "Defendants' Exhibit, large Sringfield brake, 124," in the application of the levers?

A. The levers are inside of the truck, and the fulcrum is on the rod. The end of the lever is attached to the bar.

1997 Int. 26. Are the levers on the model placed inside of the bars of the truck or outside?

A. Inside on this model.

Int. 27. The difference is, that one represents the levers as set on the inside of the brake-bars, and the other represents them as set on the outside of the brake-bars.

A. That is all the difference I see.

Int. 28. What should you judge the radius of the curve on which the cars have to be run into the car-house at Boston, when detached from the engine?

A. I should think that curve was in the neighborhood of 400 feet. It is a very sharp curve.

Int. 29. So much so that you have had to put an inner rail down?

A. It requires a guard-rail to hold the wheels on.

Int. 30. Are you in the habit of letting this train of four cars into the car-house over that curve?

A. Yes, sir; in and out every day when they are run.

Int. 31. Please state whether you have experimented to see whether there was any letting off or binding of the trucks with the old Springfield brake in passing this curve?

A. None to affect the effectual operation of the brake.

Int. 32. What is the nature of the curve at Lowell, in passing into the upper station, over which this train has to pass?

A. There is a very sharp reverse curve there.

Int. 33. Have you observed the operation of the train going in there under brakes; and, if so, what was the result of such observation?

A. None to affect the operation of the brake further than when the brake was put on upon a straight line we observed there was more strain on it when the car stood on a curve; but none to break the chains or levers. But there was a visible strain on it.

Int. 34. Did it operate to check the train, or let it loose, in passing over this curve?

A. No, it did not.

Int. 35. Please look at "Defendants' Exhibit, large Tanner brake, 123," and state what part of the same is like "Defendants' Exhibit, large Springfield brake, 124."

1998 A. Why, the application of the levers is the same, with the addition of that centre lever. The operation, I think, is the same. I mean that they are essentially the same as the Springfield brake, except that centre lever. Take the centre-lever out, and make the connection through, and it would be essentially the Springfield brake. Turn that lever over, connect it with this rod, and brake from this end, and it would be the Springfield brake.

Int. 36. By what means is the power divided or equalized between the two trucks, in both exhibits?

A. In Exhibit 123, by the centre-lever; and in Exhibit 124, by a division of power. I don't see any division of power. It is connected at the windlass by the rods; you may call that a division of power with the rods. I do not see any division of power—not practically a division. It is divided between the two trucks from the windlass. It is all applied from the windlass, a single brake to each truck, making two single brakes operated together, if you choose to call it so.

Int. 37. Is there the same means of adjustment in the two brakes when applied to cars? If so, what are the means of adjustment?

A. With these brakes, the adjustment would be by regulating the length of the rods in either. They both require it.

Int. 38. By what means?

A. By a turn-buckle, or shortening in any other way.

Int. 39. What is the means of adjusting the wear of the brake in both exhibits?

A. By nuts on the rods, in connection with nuts on the bars.

Int. 40. What advantage, if any, has the Tanner brake over the Springfield brake in generating friction power?

A. I don't think it has any advantage. I should think the Springfield brake had a little advantage over the Tanner brake, as I see the operation of them. I think, by applying the same amount of power to the Springfield brake, it would make the wheels slide a little quicker, because the same lever would apply a little more power to the wheel.

1909 Cross-examined by M'r Cozzens:

Cr.-int. 1. At what speed do the cars usually run over that curve at the Boston depot that you have spoken of?

A. They might run at the rate of eight miles an hour.

Cr.-int. 2. And about at what speed over the curve at Lowell you speak of?

A. I should think they would run eight there.

Cr.-int. 3. About what is the average speed of freight-trains in New England?

A. It is different on different roads. Some run one, and some another. Twelve miles an hour is considered a fair rate of speed.

Cr.-int. 4. How generally is the Hodge brake used throughout the New England States, as far as you know?

A. That is the general brake in use.

Cr.-int. 5. You do not know of any single brakes being used in New England on passenger-cars?

A. No, sir.

Cr.-int. 6. Or any cars running in passenger-trains?

A. Yes, sir; when they run freight-cars.

Cr.-int. 7. I mean on baggage or smoking cars?

A. No, sir.

Cr.-int. 8. In one of your early answers you said you had no more knowledge of the Springfield brake than what you had learned of it "in this present experiment." What do you refer to, when you say "this present experiment"?

A. To see whether the Springfield brake would stop a train or not.

Cr.-int. 9. As quick as the Tanner?

A. As quick as the Tanner or any other.

Cr.-int. 10. That is the experiment which has been going on on the Boston and Lowell road as to the Springfield brake?

A. Yes; if you call it an experiment.

Cr.-int. 11. Do you call it an experiment?

A. No; not hardly. I should call it a test, because it had been experimented years ago.

Cr.-int. 12. When was it experimented years ago?

2000 A. Before they had a better one to use.

Cr.-int. 13. Where?

A. On the Boston and Albany Railroad. I presume that is where the brake was originated.

Cr.-int. 14. Please state what are the lengths of the respective arms of the truck-levers in the Springfield brakes, as you have applied them in the cars of the Boston and Lowell Railroad?

A. The long arm is 30 inches; the short arm, 6 inches. The windlass shaft, at the part where the chains winds, is an inch and a half in diameter; and the windlass-wheel is 16 inches, the same as the model.

Cr.-int. 15. What is the length from the centre of the windlass-shaft to the centre of the hole in the truck-lever of the short rod and chain in the Springfield brakes, as now rigged on the Boston and Lowell road?

A. It would be 12 feet. That includes from the windlass up to the end of the lever.

Cr.-int. 16. What is the length between the centres of the windlass shafts from one end of the car to the other, on the car on which the Springfield brake is placed on the Boston and Lowell road?

A. Fifty feet. That is, it is a fifty-foot car. That includes the platform. I mean from one staff to the other.

Cr.-int. 17. How long is the long chain on those cars from centre of windlass shaft to centre of the truck lever?

A. It would be, say, 47 feet.

Redirect:

Int. 41. I would like to inquire whether the Tanner brake is used on the passenger-cars of any road within your acquaintance?

A. No; none within my knowledge.

BENJ. C. READ.

2001 *Deposition of John C. Blood.*

Int. 1. What is your name, age, residence, and occupation?

A. John C. Blood; 36 years of age; residence, Lowell; occupation, conductor on the Boston, Lowell and Nashua Railroad.

Int. 2. How long have you been conductor on that road?

A. Seven years the 25th day of last June.

Int. 3. What train do you run? By what name is it known?

A. The Boston and Lowell accommodation-train.

Int. 4. How many trips a day does it make?

A. It makes two round trips; four times over the road.

Int. 5. What is the distance between Boston and Lowell?

A. A fraction less than 26 miles.

Int. 6. What time do you have to run that train in?

A. The first train from Lowell in the morning is one hour and five minutes. The first train out of Boston, at 10 o'clock, is an hour and ten minutes. The second train out of Lowell is an hour and twelve minutes. The second train out of Boston is an hour and four minutes.

Int. 7. How many cars usually compose the train when you leave Lowell?

A. Two passenger-cars, a smoking-car, and baggage-car.

Int. 8. How many cars compose the train leaving Boston?

A. Three passenger, a baggage, and smoking car; sometimes four passenger-cars. That is my regular train.

Int. 9. What brakes are applied to what you call your regular train of four cars?

A. What they call the Springfield brake.

Int. 10. How long has that brake been applied to those cars?

A. I think it was put on some time in November; I don't know the date.

Int. 11. Have you run that train of four cars from the time it was put on to the time of leaving to come to this place?

A. I have not.

2002 Int. 12. How much time do you deduct from the whole time?

A. I can't tell you.

Int. 13. What portion of the whole time have you probably run it?

A. The greater portion.

Int. 14. How many stations are there upon the line of road at which you have to make stops?

A. I am liable to make 16 or 17 stops. Generally from 5 to 17 stops.

Int. 15. And you are required to do this in an hour and five minutes?

A. Yes; but the longest trip, when I have the most stops, I am allowed an hour and twelve minutes. Some of those are stops that I make between stations, or where I have to stop—flag-stations.

Int. 16. Are any of the stations located on curves?

A. Yes, sir.

Int. 17. How many?

A. North Billerica is on a curve; at Wilmington we strike a curve—we are on a curve when we are breaking up; at Woburn there is a curve, and also at East Cambridge. That would make four.

Int. 18. In running your train from Boston to Lowell you are obliged to make slow time, I take it, out of Boston, and *and* also into Lowell?

A. I am for the first mile, and nearly the last mile.

Int. 19. And so on returning; the first and last mile the other way is at what speed?

A. They usually tell them they want them to run six miles an hour. Sometimes they run faster and sometimes slower.

Int. 20. Notwithstanding the slow speed at the beginning and end of your run, you have to make the run in an hour and five minutes and an hour and twelve minutes, and make all the stops, whatever those stops may be?

A. Yes, sir.

Int. 21. Have you at any time during the running of this train 2003 taken it upon yourself to time the train, that is, to determine about how many seconds it takes to stop the train at each station and how long to get up speed after leaving a station?

A. I have, for about one week—six days.

Int. 22. What portion of those 26 miles did you have cars in the train equipped with other than the Springfield brakes?

A. Eight miles.

Int. 23. What brake did you have on the car or cars that you might have in the rear of the train for the first eight miles out of Boston?

A. What they call the Hodge brake.

Int. 24. After that you depended entirely on the Springfield brake on the four cars in the train going into Lowell?

A. I did.

Int. 25. And returned from Lowell to Boston with no other brake than the Springfield brake?

A. One train I had others attached, and one I had none.

Int. 26. Will you now please state, and have it recorded, the time which you made from day to day, for the six days you timed the train, with such remarks as you may think the case calls for?

A. I merely took the time for my own information. I did not expect that I should have to use it again. July 23 my delay coming out of Lowell at the Northern depot was two minutes and a half. I mean by delay the time the train remains standing. I don't know the time of stopping, because we have to run slow to the Northern depot.

From Lowell:

Bleachery	45 "	15 "

Arrived at Lowell at 5.04.

In taking the time, I set down only the five seconds. If the fraction was less than three, I took no account of it; if three or more, I called it five, which would be about an even thing.

2010 Int. 27. Please state the number of seconds, according to your record, it took your engineer to get up speed from the time he started his engine.

A. That question I am not able to answer.

Int. 28. According to your best judgment?

A. It is hard telling when an engine gets its speed. No man can answer that question.

Int. 29. I will put the question in another way. How many seconds did you consider that he consumed in getting up the speed run to make this time?

A. It would be all the way from a minute and a half to three minutes, according to the grade and the speed he had to run to get to the next station. Some of our stops would come within half a minute's run of each other, if we were running at speed.

Int. 30. How long should you judge, on the average, it took you to make the stops from one end of your route to the other?

A. I have not added it up yet. The reason I took these minutes was, I thought they might be valuable for reference some time, for my own benefit, or to satisfy my curiosity rather.

Int. 31. Who were brakemen on this train in which you made this time?

A. Alpheus Wing and John D. Emerson.

Int. 32. Did you rely upon the old Springfield brake to bring your train to rest?

A. I did.

Cross-examined by M'r Cozzens:

Cr.-int. 1. Do you consider the Springfield brake a first-rate brake?

A. I do. I know it does its work. I have not used brakes enough to know whether it is the best brake; but I consider that it has done the work on my train.

JOHN C. BLOOD.

2011 *Deposition of Alpheus Wing.*

Int. 1. What is your name, age, residence, and occupation?

A. Alpheus Wing; age, 35; residence, Lowell; occupation, brakeman on the Boston, Lowell and Nashua Railroad.

Int. 2. How long have you been brakeman on that road?

A. I have been brakeman on the road and its branches about four years.

Int. 3. On what train are you brakeman now?

A. M'r Blood's train.

Int. 4. When does said train leave Lowell, and when Boston?

A. It leaves Lowell at 7; Boston at 10; Lowell at 2.15, and Boston at 4.

Int. 5. Were you one of the brakemen for M'r Blood at the time he timed the train, noting the number of seconds in which the stops were made?

A. I was on at that time; yes, sir.

Int. 6. Have you about concluded your services on that road as brakeman?

A. I expect I have.

Int. 7. What position do you expect to occupy hereafter?

A. I expect to be in the depot.

Int. 8. In what capacity?

A. Assistant depot-master.

Int. 9. How long have you been brakeman on this train of M'r Blood?

A. Two years and six months.

ALPHEUS WING.

Deposition of John D. Emerson.

Int. 1. What is your name, age, residence, and occupation?

A. John D. Emerson; 35 years old; residence, Lowell, Mass.; occupation, brakeman on the Boston and Lowell Railroad.

Int. 2. How long have you been brakeman on that road?

2012 A. About a year and a half.

Int. 3. And how long on M'r Blood's train?

A. Since last October.

Int. 4. Do you act as rear or forward brakeman?

A. Rear.

Int. 5. And have you been a brakeman almost all the time on that train since last October?

A. I have.

Int. 6. Were you on it at the time when M'r Blood made a record of the time of the stops?

A. I was.

Int. 7. And you broke the two cars in the rear of the train?

A. Yes, sir.

Int. 8. Were the cars on that train equipped with what is called the old Springfield brake?

A. Yes, sir.

Int. 9. Two chains winding on either windlass?

A. Yes, sir.

Int. 10. Have you concluded your service as brakeman on that road?

A. I have.

Int. 11. In what capacity do you expect to be employed hereafter?

A. Conductor.

Int. 12. On what road?

A. Boston and Lowell Railroad.

JOHN D. EMERSON.

Deposition of Robert Hitchcock.

Int. 1. What is your name, age, residence, and occupation?

A. My name is Robert Hitchcock; age, 43; residence, Springfield; occupation, building and repairing cars for the Connecticut River Railroad Company.

Int. 2. Have you charge of the car department of that road?

2013 A. I have.

Int. 3. How long have you had such charge?

A. Since June, 1856.

Int. 4. Are you acquainted with the construction and operation of railroad-car brakes?

A. I am.

Int. 5. With what brakes are you acquainted?

A. With what is styled the old single brake, the old Springfield brake, the Tanner, Hodge, and Stevens brakes.

Int. 6. You name the old Springfield brake; how long have you been acquainted with it, and when did you first know it?

A. I have been acquainted with it since 1846. I first knew it in the fall of 1846, on what is now termed the Boston and Albany road, in this city.

Int. 7. Where did you see it; on what car or cars, if at all?

A. I saw it on the tenders of locomotives.

Int. 8. You will please look at "Defendants' Exhibit, old Springfield tender-brake," and state whether that is a correct representation of the application of the brake, as you saw it in 1846 and thereafter.

A. It is.

Int. 9. Is the application of the levers to the truck-bars the same now as then, or have they been modified?

A. In principle it is the same, but the fulcrum of the lever is not now put upon the bar instead of the short arm. In other words, the lever is now placed at the end of the truck furthest from the windlass instead of where it was originally, at the end of the truck nearest the windlass. It was my business to work upon those tenders at that time, and we placed the lever at the end of the truck nearest the windlass, on both sides of the bar, and also with its fulcrum in both places, one way on the bar, and the other way on the lever.

Int. 10. What brake is in general use on the Connecticut River Railroad?

A. The Hodge brake.

Int. 11. Have you in use the old Springfield brake; and, if so, to what extent?

2014 A. We have it in use upon four cars.

Int. 12. Any Tanner brakes in use?

A. We have one car.

Int. 13. Will you please describe the manner of applying the levers to the bars of the trucks in the application of the Springfield brake to the cars of that road?

A. On one car it is precisely the same as this "Model A, E. Merwin, U. S. C." Upon the other three cars the levers are applied the same as in "Defendants' Exhibit, old single brake"; that is, the levers to which the short chains run are placed at the end of the trucks furthest from the windlass. In all respects it is like "Defendants' Exhibit, old Springfield brake, 124," with the exception that the fulcrums of the levers are placed upon the truck-bars instead of the short arms, like said exhibit old single brake.

Int. 14. What is the estimated weight of the four cars to which this brake was applied, and also the weight of the engine and tender which were and are used to haul the train?

A. Seventy tons and 390 pounds is the actual weight of the cars; the weight of the engine and tender is thirty-eight tons and ten pounds; making the whole train weigh a little over 108 tons.

Int. 15. What name is given to the train equipped with this brake?

A. Sampson's train.

Int. 16. Where is it run?

A. It runs between Northampton and Springfield and between Chicopee Falls and Springfield.

Int. 17. Who is engineer?

A. Henry Wright was until quite recently. I don't know who is running it now. There have been different engineers.

Int. 18. Who are the brakemen?

A. William McCormick and Frank Bennett.

Int. 19. What is the radius of the sharpest curve on which this train runs, and where is it located?

A. 350 feet. It is located in this city, near the terminus of our track.

2015 Int. 20. Is it in the main track over which this train has to run in coming into the station in this city?

A. It is near the depot.

Int. 21. Has any complaint come to you that the chains which wind on the brake-shafts, in operating the brakes, overlap each other, and thus destroy the effective operation of the brake?

A. No, sir.

Int. 22. Can there be any overlapping of chains? If so, state under what circumstances, and what the remedy.

A. If the brake should be neglected, and the turn-buckle should turn back and lengthen the rod that connects the truck furthest from the windlass, the chains might possibly come down and overlap. It would be remedied by taking up the rod on which the turn-buckle is placed.

Int. 23. Is this brake any more liable to be complained of than any other brakes, such as the single brake, Tanner brake, and Hodge brake?

A. No, sir.

Int. 24. Of all brakes, which do you have the most complaint from?

A. Well, I don't know. They complain of all brakes. They complain of the Hodge at times, and of the Stevens. I never have heard any complaint, however, of this brake, the Springfield; but there are circumstances or times when brakemen will complain of brakes when there is no necessity for it.

Int. 25. Will you please look at "Defendants' Exhibit, large Springfield brake, 124," and state what is the prominent characteristic of that brake, that which distinguishes it from all others?

A. It is the combination of the levers in both trucks with each other and with the windlass on the car body in opposite directions.

Int. 26. Please state what you mean by "opposite directions."

A. I mean that it has two systems, one operating from one end of
the car, and the other from the other; two levers being connected
2016 with one windlass, and two with the other, in opposite directions,
but in the same relative position, the pairs operating independently of each other.

Int. 27. Would you note the same characteristic in the said exhibit should you connect the levers in the trucks with each other, and then with the windlass, by one chain?

A. I should.

Int. 28. Having one chain or two chains does not change the characteristic of the brake?

A. No, sir, not at all.

Int. 29. You will now please look at Defendants' Exhibit, large Tanner brake, 123, and state what its leading characteristic is.

A. It is characterized by connecting the levers between the trucks by the use of a centre-lever.

Int. 30. Do you mean the power between the trucks or truck-levers on the trucks by means of a centre-lever?

A. Yes, the connecting levers.

Int. 31. And through the centre-lever with the windlass of the car?

A. Yes, sir.

Int. 32. Does it alter the characteristic of either of these brakes whether you put the fulcrum of the truck levers on the bar or the short arm of the bar?

A. No, sir.

Int. 33. Or whether you put the lever inside or outside of the bar?

A. No, sir.

Int. 34. You will please answer the same question as to the leading characteristic of the Hodge brake.

A. The Hodge brake equalizes the power between the trucks.

Int. 35. By what means?

A. By the use of two levers, which are suspended upon movable links.

Int. 36. Wherever you find the Hodge brake, do you always find this characteristic of the two truck-levers being connected by two equalizing levers, suspended on links?

A. Always.

Int. 37. It makes no difference, then, about the arrangement of the levers in the truck?

2017 A. Not at all.

Int. 38. What is the leading characteristic of the Stevens brake? What is that a combination of; and how are the parts worked?

A. It is a combination of the four levers of the old Springfield brake with each other and with the windlasses on the car body.

Int. 39. And operated how?

A. It operates in one system, from either end of the car.

Int. 40. While the Springfield brake is operated as two systems, or in pairs, from either end of the car?

A. Yes, sir.

Int. 41. Can the old Springfield brake be converted into a Stevens brake?

A. It can.

Int. 42. Look at Defendants' Exhibit, old Springfield brake, 124, and if you think you can convert it into a Stevens brake, do so, and state while doing it the process in detail.

A. I first disconnect the levers between the trucks from the windlass. I will now proceed to connect the fulcrums of the levers in the trucks. I will now connect the two levers between the trucks with each other.

Int. 43. And then what do you have?

A. I have the Stevens brake.

Int. 44. Were you a witness to certain experiments with the Tanner brake some time last November?

A. I was.

Int. 45. Please state in general the object of the experiments.

A. The object was to prove the difference between the same power applied to a brake-wheel upon four wheels and upon eight.

Int. 46. You will now please state in detail how that object was carried out.

A. We took a car with the Tanner brake applied the same as on Exhibit 123. We went to a point marked by a bridge, using 120 pounds
steam pressure. We had a brakeman, a helper, and myself. We
2018 attained the highest speed that we could in running a certain dis-
tance, which was marked by a switch. We estimated the speed
at twenty-five miles an hour. At this switch we sounded the whistle; the brakeman was at his post, the man ready to draw the pin simultaneously, and the brake was applied—first with the Tanner brake, as it now stands in that exhibit. We ran I do not know how many feet, but we marked the place where we stopped. We then converted the brake

into what is termed the old single brake, by disconnecting the lever of one truck from the centre lever. We went over the ground again, all things being equal, and stopped very nearly in the same place. I think we passed about somewhere in the neighborhood of the length of the car further. We were surprised ourselves in one sense; and we tried the experiment again the same way, with just about the same results. We then coupled it up, making the Tanner brake good again, and went over the ground once more. The same instructions were given to the brakeman in each case, and all the conditions the same, and about the same results were obtained that we did with the first trial of the Tanner brake.

Int. 47. What conclusion, if any, did you deduce from these experiments?

A. We made up our minds that the friction was due to the weight or pressure more than to the amount of surface that it covered.

Int. 48. That is, that the law of generating friction is as the pressure, not as the surface pressed on?

A. Exactly. When operated as a single brake, the wheels slid a little ways. The brakeman was a common man, not acquainted with applying brakes. All that he could do was to exhaust his force upon the windlass. If he had, at the point where the wheels began to slide, let up on his chain, I think that the result would have been the same as with the Tanner brake, or nearer than it was. I became satisfied that if a man exhausts his force upon a single brake, and does not slide the wheels, he does just as much service as he does when he exhausts his force under the same conditions on the double brake, not sliding the wheels.

2019 Int. 49. In applying friction to car-wheels, for the purpose of stopping the car, are the wheels ever made to slide when the car is at high speed?

A. No, sir; that is impossible.

Int. 50. When do they, if ever, slide?

A. When the car is nearly at rest.

Int. 51. Then do I understand you, that the conclusion arrived at from these experiments was, that a brake is doing just as effectual service so long as the wheels are in motion with a certain power, whether applied to four wheels or eight wheels, so long as the wheels are not brought to rest?

A. That was my conclusion.

Int. 52. You will now please look at "Defendants' Exhibit, large Tanner brake, 123," and wind up the larger windlass until the scales in each truck indicate 48 pounds, and set down the dog in the ratchet. (Witness did as directed.) You will now take "Exhibit, round scale," and apply it to the periphery of the wheel, and state how many pounds it takes to lift the dog from the ratchet.

A. Two pounds.

Int. 53. You will now disconnect one of the truck-levers from the centre-lever, thereby resolving the brake into a single brake, and turn up the smaller or twelve-inch windlass-wheel until it indicates 48 pounds in the truck to which the windlass is attached. (Witness complied with the request.) You will now apply to the periphery of said wheel "Exhibit, round scale," and state how many pounds it takes to relieve the dog in the ratchet.

A. Two pounds.

Int. 54. What conclusion do you deduce from the facts elicited by the two experiments?

A. That the power transmitted through a 16-inch wheel upon a double brake is equal to the power transmitted through a 12-inch wheel to a single brake.

Int. 55. Then is it proper or not to conclude, that no more power can be conveyed to a single truck by a 12-inch wheel than to the brakes of two trucks by a 16-inch wheel ?

A. It is proper.

Int. 56. Do you know of the use of the Tanner brake on the passenger-cars of any railroad ?

2020 A. I do not.

Int. 57. By what brakes has it been superseded ?

A. The Hodge and Stevens.

Int. 58. Please state, having reference to the "Tanner Patent Office Model," whether or not it would be practicable to apply the brake as therein represented to a car; and, if not, why not ?

(Counsel for plaintiff objected, on the ground that no such issue arises upon this accounting.)

A. It would not, because it has a compound lever, which would give us too much chain; likewise, too much power. If we should attempt to remedy the chain, we should have to increase the shaft on the windlass-wheel, but would not increase it sufficiently so but that we should slide the wheels. In the first place, we have a centre-lever which we take hold of from the windlass, equi-distant from its centre at either end. The power is transmitted to the lever of the truck by the shorter arm of the same lever. In other words, this result I speak of is due to the fact that the windlass rod takes hold of the centre-lever at the end of the latter, and the rod of the truck-lever goes from the centre-lever at a point which is nearer the fulcrum-pin than it is to the end of the centre-lever, as seen in said Patent-Office Model. That is why I think it would be impracticable to apply a brake to a car as in that model.

Int. 59. From the data already established, which mode of application, in your judgment, would slide the most wheels, the brake represented in the Patent-Office Model or the same power applied to the single lever of a single truck ?

(Counsel for plaintiff objected, upon the same ground as before.)

A. The brake in the Patent Office Model.

Cross-examined by Mr. Cozzens:

Cr.-int. 1. Which do you think is the best brake, the Hodge or the Stevens ?

A. The Hodge.

Cr.-int. 2. You made these two large wooden models, Springfield, 124, and Tanner, 123 ?

A. No, sir; but they were made in the shop I have charge of.

2021 Cr.-int. 3. What are the numbers of the cars on the Connecticut River road upon which the four Springfield brakes you have spoken of are placed ?

A. No. 4, baggage and smoking-car, passenger cars M, T, and U.

Cr.-int. 4. Which one of those has the brake like the "Model A, E. Merwin, U. S. C. ?"

A. Passenger-car M.

Cr.-int. 5. On this car M, how long are the respective arms of the truck-levers on the brake ?

A. The long arm is 30, and the short arm 6 inches.

Cr.-int. 6. On said car M, how long is the short chain and how long s the long chain, from centre of windlass-shaft to centre of top of ever ?

A. I cannot say exactly. I should say somewhere from four to five feet.

Cr.-int. 7. And how long the long chain and rod between the corresponding points?

A. In the neighborhood of 25 feet.

Cr.-int. 8. How long is the whole car between centres of windlass-shafts?

A. In the vicinity of 47 feet.

Cr.-int. 9. This car M, of course, has a platform at each end?

A. Yes, sir.

Cr.-int. 10. What is the width of the platform?

A. Two foot and a half from the standard back, or thereabouts.

Cr.-int. 11. Are you including this portion here of the frame with the platform?

A. Yes, sir; everything. I mean from the standard of the brake to the body of the car.

Cr.-int. 12. And the brake-wheel on that car is 16 inches in diameter, and the part of the windlass shaft where the chains wind is an inch and a half in diameter, is it?

A. I think they are.

Cr.-int. 13. Please give the same data as to cars U, T, and No. 4.

2022 A. The long arms of the truck-levers are 30, the short arms are 6 inches. The shorter chain and rod is 10 feet; the length of the longer chain and rod is 45 or 46 feet, or thereabouts.

Cr.-int. 14. Then, as I understand it, you mean that in this case the shorter chain and rod is about 10 feet, the longer chain and rod is about 25 feet, and the same for the longer chain and rod in the other case?

A. Exactly.

Cr.-int. 15. And the width of the platform?

A. The width of the platform is the same—two feet and a half.

Cr.-int. 16. What is the total length of the car-bodies, U, T, and No. 4, between centres of windlass-shafts?

A. About 50 feet.

Cr.-int. 17. What is the length of the trucks of those four cars, M, T, U, and No. 4?

A. Nine feet seven inches. They are all the same.

Cr.-int. 18. Please to state the total lengths of the car-sills, exclusive of the platforms and bunter-beams.

A. The M car is 42 feet; U and T 45 feet, or thereabouts; No. 4 is 45 feet.

Cr.-int. 19. How much do you allow for the width of platforms and bunter-beams at each end of those cars?

A. Two feet and a half.

Cr.-int. 20. What other cars, if any, run in these trains with the cars having the Springfield brakes on?

A. There are no others.

Cr.-int. 21. This train has all Springfield brakes?

A. Yes, sir; if any other one gets in it is by accident. On extra occasions, if we have occasion for an extra car, we have no others equipped with that brake, and we hitch on another car without reference to it; but it is rarely if ever done.

Cr.-int. 22. Do all these cars which you say have the Springfield brake on them run regularly together in one train?

A. Not all the time. They do when we require them all; when we require as many cars as four. Three cars is the regular train as a rule.

2023 Cr.-int. 23. Have at least three of these cars, fitted with the Springfield brakes, run regularly in this train?

A. Yes, sir.

Cr.-int. 24. For how long a time?

A. Since some time in November up to the present.

Cr.-int. 25. At least three have run regularly in that train during all of that period?

A. It may be possible we have had one of them in the shop to varnish the car.

Cr.-int. 26. Then you would put on the other one, wouldn't you? I am not particularizing the cars, but you run three cars regularly?

A. Yes, sir; we run three cars.

Cr.-int. 27. Which is uppermost, the long chain and rod or the short chain and rod?

A. The short chain and rod, I think. I am not positive, but I think it to be so.

Cr.-int. 28. Will you please state whether you have any corrections to make in your testimony in regard to the length of the short chains and rods of the Springfield brakes on one or more of the cars of the Connecticut River Railroad?

A. I have a correction to make. The length is from 12 to 12½ feet.

Redirect:

Int. 60. Were you ever in the employ of the Western Railroad Company, now the Boston and Albany?

A. I was.

Int. 61. When did you first come into the employ of said Western Railroad Company?

A. In the fall of 1846.

Int. 62. At the time that you came into such employ were you acquainted with the tenders then in use on that road and the application of brakes to the same?

A. I was.

Int. 63. How did you find the application of the levers to the trucks on the different tenders?

A. Some, I think, were precisely the same as this model, "Defendant's Exhibit, old Springfield tender-brake." Some, I think, 2024 had the first truck lever set on the bar the furthest from the windlass. Then they were connected in the same way they are in this exhibit.

Int. 64. Do you wish to be understood that the levers were set upon the bar the furthest from the windlass, the same as shown in "Defendants' Exhibit, old single brake;" and at what time did you see levers so applied upon tenders on the Western road?

A. I do. That was in the fall of 1846. I found them so when I came there.

Int. 65. Do you know how long they had been thus applied prior to your going?

A. I do not.

Int. 66. Are they applied now upon the tenders of that road the same as you saw them in 1846?

A. Some of them are; I can't say how many.

Int. 67. In the operation of the old Springfield brake upon the cars of your road to which it is applied have you noted that one of the windlass chains sometimes drops a little upon the standard in winding upon the same? If so, how does that affect the practical operation of the brake?

A. I have noticed on one car, No. 4, one of the chains dropping a little. I don't consider that it affects the operation of the brake at all, to injure it. If one chain falls down by being slack it tends to adjust it by shortening its length.

Int. 68. Would this be the case if the chains and rods were adjusted alike, so as to apply the power equally on each truck?

A. No, sir; it would not.

Int. 69. Look at "Tanner Patent-Office Model" and note the point of connection of the truck-levers with the centre lever, and state whether this brake, when applied to a car as indicated in the model it should be, would apply more or less power to the brake-bars on each truck than would the same brake when attached to the lever on one truck.

A. It would apply more power to two trucks.

Int. 70. Will you prove it by reference to "Defendants' Exhibit, large
Tanner brake?" (Witness connected one truck-lever with the
2025 first screw in the centre lever from the end, on each end of the
lever.) Will you please wind up the 16-inch wheel or larger wheel until the scale indicates 48 pounds in each truck and set down the dog in the ratchet? (Witness did as directed.) You will now take "Exhibit, round scale," and state how many pounds it takes to relieve the dog in the ratchet.

A. One pound.

Int. 71. You will now make a connection with the second screw, from the end of the lever upon either side of the centre of the lever, and state whether the connection as thus made is a correct representation of the connection as seen in the Patent-Office Model.

A. As near as I can approximate by measurement it is correct.

Int. 72. You will now wind up the larger windlass until you have exhausted all the rope, and state how many pounds are indicated on the scale in each truck.

A. Forty.

Int. 73. You will now take "Exhibit, round scale," and state how much it takes to relieve the dog in the ratchet.

A. Half a pound.

Int. 74. Would a brake applied as now seen in "Defendants' Exhibit, large Tanner brake," which you say is the same as applied in the Patent-Office Model, be a practical operative brake as applied to a railroad car?

A. It would not.

Int. 75. Will you give the reason why it would not?

A. It would apply too much power and require the use of too much chain. There would be too much play upon the levers.

Recross:

Cr.-int. 29. Have you ever noticed the fact in the Springfield brake that one chain would wind spirally on the windlass-staff, before last Saturday, when M'r Sayles pointed it out to you and M'r Adams on car No. 4?

A. I never did.

Cr.-int. 30. Do you recollect whether the chain caught on the eye?

A. It caught on the eye at this time. That was caused
2026 by the excess of chain falling in that direction, by the brake be-
ing on the opposite end. When he called my attention to this the brake on the opposite end was applied so it threw the excess of chain on the end we were examining, both rods coming in that direction indiscriminately, as the levers would go in that direction when the brakes were applied at the opposite end.

Cr.-int. 31. Did you examine the same car this morning; and, if so, will you state whether the brakes were loose, and whether you saw the man apply the brakes, and saw the chain catch on the eye at both ends of the car when it was applied, and twist the chain, and wind the chain spirally around the staff?

A. I did. The brakes were loose. I saw the man apply the brakes; and I saw the chain catch, but only as it ordinarily does in all brakes. The chain was wound slightly in a spiral manner around the shaft.

Cr. 32. Did you examine car U this morning and see the brake applied on it, and did you notice the same catching of the chain on the eye, and the same winding spirally of the chain on the brake-staff?

A. It might have been so, but I didn't happen to observe it.

Cr. 33. Suppose that the two chains of this Springfield brake should, from winding spirally, or other cause, draw unequally, would not the action upon the two trucks of the car be unequal?

A. That must be the result.

Redirect:

Int. 76. Would such assumed inequality injure the effective operation of the brake materially, in your judgment?

A. No.

Int. 77. Does it alter or change the effective operation of the old Springfield brake whether the chain connected with the long rod is connected with the windlass above or below the chain which runs to the lever nearest the windlass?

A. It does not. I should as soon set them one way as the other.

2027 Recross:

Cr.-int. 31. You say that the above assumed inequality would not injure the effect of the brake in your judgment; would not the question whether it injured the effect of the brake or not entirely depend upon how great the inequality was?

A. It would.

Redirect:

Int. 78. You seem to give preference to the Hodge brake compared with the Tanner brake and with the old Springfield brake. Is that so?

A. It is.

Int. 79. You will now please give your reasons, somewhat in detail, for such preference.

A. Because an application to a car is more easily made, and less skill is required to take care of it. And when it is not properly adjusted, it has an adjusting element at the command of the brakeman, by taking up the chain on the windlass at the opposite end from which he applies the brake. And because the power is always equally divided between both trucks when the car passes from a straight line on to a curve under the brake. What I mean by that is, that the Hodge brake, when applied upon a straight track, and it passes on to a curve, retains the same pressure upon both trucks, which is an element that no other brake possesses, except the Stevens brake.

Int. 80. Can you illustrate by "Defendants' Exhibit, large Tanner brake" (No. 123), the increase and decrease of power on each truck when the trucks are thrown out of line by passing from a straight line on to a curve under the brakes? If you say you can, please do so.

A. I can. I will first separate the piece representing the car-body from the trucks, by means of temporary supports. Secondly, I will wind up the windlass until the scales on the connecting-rods of each truck

indicate forty (40) pounds with the trucks in line. Thirdly, I will now place the trucks one inch and one quarter out of line, assuming a position they would hold in passing on to a curve. I now find the
2028 scale on the truck nearest the windlass, from which the power is applied, indicates forty-six pounds, while the one farthest from the same windlass indicates thirty-four pounds.

Int. 81. What change, if any, would take place in the power applied to each truck were the car to pass on to a curve the reverse of the one on which you have just placed the trucks of the car, as represented in said exhibit (123)?

A. The same difference would be shown upon the scales, except that the one that now shows the most would then show the least.

Int. 82. And would this power change from one truck to the other as the car passes from a right to a left-hand curve?

A. It would.

Int. 83. And would the power be restored to each truck as originally indicated in passing from the curve on to a straight track?

A. It would.

Int. 84. What have you to say in reference to the old "Springfield brake," touching the matter you have just illustrated, in reference to the old Tanner brake?

A. It is precisely the same.

Int. 85. How is the Hodge brake affected by these circumstances?

A. The pressure upon each truck is not changed, but always equal on a straight track and curve; that is, when passing from a straight track to a curve.

Int. 86. How would the Tanner brake be affected were the shoes of unequal thickness on the two trucks?

A. It would lose its equality or adjustment. The pressure on the two trucks would not be equal, the result tending to resolve it into a single brake.

Int. 87. How would the Hodge brake be affected were the shoes of unequal thickness on the two trucks?

A. The operation of the brake would not be affected.

Int. 88. Would the power be the same, or practically so, on each truck of the Hodge brake when the shoes are of unequal thickness? If you say it would, give your reason.

2029 (Objected to.)

A. It would. Because the power is always equally divided on the trucks, by means of swinging or sliding links in combination with the two equalizing levers between the trucks.

Int. 89. So far as holding the car under the brakes is concerned, is there or not any material difference between the Hodge brake, the old Springfield brake, and the Tanner brake, the levers in the windlasses and truck-levers in all the brakes being the same?

A. There is not.

Int. 90. Wherein, then, is the Hodge brake a more acceptable brake to railroad companies than either the Tanner or Springfield brakes?

A. It requires less skill to take care of it. It is not liable to lose its adjustment, and imparts the same power to each truck when upon a straight track or otherwise?

Recross:

Cr.-int. 32. Which do you consider the best brake, the Hodge or the Stevens?

A. The Hodge.

Cr.-int. 33. Why? Give your reasons.

A. I consider the Hodge brake more practical, because it does not lose its adjustment, compared with the Stevens.

Cr.-int. 34. Does a large number of the Vermont Central passenger-cars run over the Connecticut River Railroad, and have they the Hodge brake attached to them?

A. A few of them; but I am not positive what brake they have on them.

Cr.-int. 35. How long have they run over your road?

A. More or less during the last ten years or longer, to my knowledge.

Cr.-int. 36. Do the brakemen employed by the Connecticut River Railroad operate the brakes on these cars when running on their road?

A. They do.

Cr.-int. 37. You don't know, then, what brakes are used on the Vermont Central cars?

2030 A. I do not.

Cr.-int. 38. You see more or less of their cars daily around your shops?

A. I do, but have no care of them.

Cr.-int. 39. Is the Hodge brake attached to all of your passenger and baggage cars, except what have the Springfield brake on?

A. It is not.

Cr.-int. 40. What other brake?

A. The Stevens and Tanner brake, one of each.

Cr.-int. 41. Do the Hodge brakes on all of your cars all work equally well, so far as you know?

A. They do, on the same weight of car.

Redirect:

Int. 91. What defect is there in the Tanner brake that is not found in either the old Springfield brake, the Hodge brake, or the Stevens brake?

A. The Tanner brake loses its adjustment when the brake is applied upon a straight track, by means of a play about the centre-pin which passes through the lower frame-work of the car, and likewise through the balance-beam of the truck; and also to a play each side of the balance-beam and the centre-plates upon which the car rests on the truck, which allows the forward truck to fall back towards the centre-lever, giving less tension to the rod which connects the centre-lever to the truck-lever. It also allows the rear truck to fall back from the centre-lever, giving more tension to the rod which connects the truck-lever to the centre-lever. The result tends to resolve it into a single brake.

Int. 92. How is this defect increased or decreased by the wear about the balance-beams and centre-pins of the truck?

A. It is increased. When a car is new, it is in each truck from one-half an inch to an inch, when under the brake with the car in motion; and I have seen them, when worn, varying up to two inches.

Int. 93. Then the greater the wear or looseness of the balance-beam and centre-pins the greater this defect. Is that so?

2031 A. Yes.

Int. 94. Why is not the same defect observable in the old Springfield brake?

A. Because when the trucks fall back from the windlass more tension is put upon both rods that connect the truck-levers to said windlass, which affects the brake upon both trucks equally.

Int. 95. Does the same answer apply to both the Stevens and Hodge brakes?

A. It does.

Int. 96. Has your attention been called to the chains upon the windlass-staff of the old Springfield brake winding spirally on the shaft; if so, by whom; and what conclusion did you come to from the observation?

A. My attention has been called to it by M'r Sayles, the complainant. I concluded that it had a self-adjusting element, from the fact that if the chain was too long it would take a spiral form upon the shaft until its tautness was equal to its companion, and then would travel equally with it.

Int. 97. Have you read 141st direct interrogatory put to D. F. Adams, in this case, and the answer thereto; if so, do you concur with him in the statements therein made?

A. I have read them, and do concur with M'r Adams' statement fully.

Int. 98. How many cars are included in the experiment conducted by yourself and M'r Adams, for the purpose of determining the longitudinal motion of the bodies of cars upon the trucks, and what is the average number of inches of such longitudinal motion?

A. Thirteen cars were tried besides the one mentioned by M'r Adams as being excessively strained against the head-block. The average number of inches was 1⅛ inches.

Int. 99. In your judgment, is that a fair average of motion between body of car and trucks, as trucks are now constructed?

A. I so consider it.

Int. 100. What, in your judgment, would be a fair average of motion between body of car and trucks, as they were constructed ten or more years ago? Whatever your answer may be, give your reasons.

2032 A. One inch and one-half. This is on account of the narrowness of the swing-beam and size of the springs upon which it rested. At that time the balance-beam was 7½ inches wide generally on roads in New England, and especially upon the Connecticut River Railroad; and also the length of the suspending link, which allows the springs to turn over, with the beam forward and back, more readily than it does at the present day, with beams that range from 12 to 20 inches wide, and springs correspondingly spread. Improvements have been made, also, in the guides or friction-plates by making them larger; and also the transom timbers of the trucks are made larger, so that they do not spring as much under the pressure.

Int. 101. Have you read 140th interrogatory in this case, put to F. D. Adams, and the answer thereto? If so, are the satements therein made by him, according to your own knowledge and observation?

A. I have read said answer. I was present at the trials referred to, and consider M'r Adams' statement correct. I didn't measure the distance, but M'r Adams did; and I agree with him in the conditions as stated by him.

Int. 102. What instructions did you give to the brakeman before entering upon the duty assigned to him?

A. I told him to do justice in every trial, by applying the brake at the sound of the whistle as hard as possible—to use all the power he could exert each time.

Int. 103. Please give the diameter of the brake-wheel; also the shaft on which the chain is wound in operating the brakes; also the length of the long and short arms of the levers in the trucks; and also the length of the centre-lever, together with the kind of shoes, whether wrought or cast iron, on the car used for this experiment?

A. The diameter of the brake-wheel was 16-inch. The shaft is 1¾ inches in diameter. The long arms of the levers are 27 inches; the short arms, 6 inches. The centre-lever is 4 feet long, I think; but I can't be positive. The shoes were wrought iron.

Int. 104. How are the lever connections and brake-wheel connections made to the centre-lever?

2033 A. They are connected in line; that is, at the end of the centre-levers.

Int. 105. M'r F. D. Adams, in answer to 59th cross-interrogatory in this case, has alluded to a reverse curve, located between the track east of the depot in Springfield, but was not able to state the radius of said curve. Have you measured the verse sine of that curve on a chord of 40 feet and 7 inches? If so, with what result?

A. I have measured it; the verse sine is 2¾ inches.

Int. 106. Why did you take the measurement from a chord of 40 feet and 7 inches?

A. Because it was the distance from centre to centre of trucks of Boston and Albany passenger-car No. 142, being one of their longest cars, and of recent build.

Int. 107. In answer to the 19th direct interrogatory in this case, you say that the radius of a curve on the Connecticut River Railroad, located near the terminus of said road in this city, over which all passenger-trains have to pass, is 350 feet. What is the verse sine of a portion of that curve the chord of which is 35 feet, or the average length of the cars in the train on said road that has been run with the old Springfield brake applied?

A. Six inches. I did not arrive at this by figures, but by actual measurement upon the track.

Int. 108. What would be the deflection of the trucks of a car the wheels of which have a six-feet span—that is, from wheel centre to wheel-centre—from a line parallel to the body of the car, when run upon this curve?

A. Two inches.

Int. 109. How would this deflection of two inches affect the practical operation of any brake that might be applied upon passing over said curve under the brakes?

A. The effect would not be perceptible to the operator or to any one else; at least, such is my experience upon trial.

Int. 110. Please state what trial you have had, and when, to satisfy yourself upon this point?

A. I had trials upon this same curve in November last, by applying the brake upon a straight track, and passing on to the curve under the brake.

2034 Int. 111. What brake was used for the experiment?

A. The old Springfield brake; same as seen in "Model A, E. Merwin, U. S. C."

Recross.

Cr.-int. 42. What was the letter or number of the car with the Springfield brake on, like the model, and which you said you tried last November?

A. Letter "M."

Cr.-int. 43. Have you lately taken the Springfield brakes off from any of the cars on which you have recently had them, on the Connecticut River Railroad?

A. We have.

Cr.-int. 44. How many of them have you taken off?

A. Three.

Cr.-int. 45. Did you take them off in order to put on the Westinghouse air-brake?

A. Yes.

Cr.-int. 46. What form of double-acting brake have you put on these three cars in order to apply the Westinghouse brake?

A. Hodge brake.

Cr.-int. 47. In the Hodge brakes on the cars on the Connecticut River Railroad, have some of the windlass-staffs got worms at the lower ends?

A. Yes, sir.

Cr.-int. 48. And some of the windlass-staffs of said Hodge brakes, upon your road, are plain at the lower ends; that is, are without any worms, are they?

A. Yes, sir.

Cr.-int. 49. You have spoken of experiments made with a car having the Tanner brake, and then having one of its trucks disconnected, at which you said you were present. Was it the object of these experiments to see if you could stop the car as quickly with one truck disconnected, to make what you call a single brake, as you could with a double brake?

A. It was.

2035 Cr.-int. 50. Suppose a car brake to be proposed to you as a double-acting brake; and suppose that, in that brake, after the parts had been so adjusted that the brakes would operate properly while the car was on a straight track, the natural tendency was that, when the car with the brakes applied passed from a straight track on to a curved track it would cause the brakes of one truck to bind so hard as to slide the wheels of that truck, and would loosen the brakes of the other truck; would such a brake be a practical one for use on railroads?

A. I have had no experience with any such brake.

Cr.-int. 51. Would such a brake, in your judgment as a practical car-builder, be a practical brake?

A. I couldn't judge of it without seeing it. It might be modified.

Cr.-int. 52. Suppose it was not modified, but operated as in the hypothesis given you, would it be a practical brake?

A. To a certain extent it would be practical.

Cr.-int. 53. To what extent?

A. To the extent of a single brake, so called.

Cr.-int. 54. Which brake would be acting as a single brake—the one attached to the truck where the shoes were loose, or the one attached to the truck where the wheels were slid?

A. The one that absorbed the power from the windlass.

Cr-int. 55. Would not the one which absorbed the power from the windlass be the one where the wheels were slid, according to the supposition?

A. If any, it would.

ROBERT HITCHCOCK.

Deposition of W'm H. Stearns.

Int. 1. What is your name, age, residence, and occupation?

A. My name is W'm H. Stearns; my age, 50; residence, Springfield; occupation, master mechanic of Connecticut River Railroad Company.

Int. 2. Did you yesterday witness certain experiments with a 2036 double and single brake? If so, please state how those experiments were conducted, and what instructions you gave to the engineer who run the engine.

A. I did witness such experiments. We started, at a certain point, with an engine attached to a car. We shut off steam at a certain point and pulled the pin that connected the engine with the car, and the brakeman stopped the car as soon as he could, apparently. My instructions were to the engineer to keep the same pressure, use the same quantity of steam, and shut off at the same point, blowing the whistle when he shut off.

Int. 3. How many trials were made with the single and how many with the double brake? And what were the results, according to your observations?

A. We made two trials with each brake. The cars with the single brake stopped within a foot of where it did with the double brake.

Int. 4. What should you judge was the speed of the engine at the time the pin was pulled and the whistle blown for brakes?

A. I should judge from 25 to 30 miles an hour.

Int. 5. What were your means of judgment?

A. I was on the ground, and judged by the sound or quickness of the exhaust as much as anything.

Cross-examination by S. D. Cozzens:

Cr.-int. 1. Please state what was done with the double brake, to make what you have called the single-brake trials in these experiments.

A. We unhooked the rod running from the centre-lever to one of the truck-levers for the first single-brake trial, and then braked from the windlass, which was at the same end of the car as the truck-lever, which we disconnected. For the second single-brake trial we reconnected the truck-lever just spoken of, to the centre-lever, and then braked from the windlass opposite the one we used in the first trial.

Cr.-int. 2. Did you come to any conclusion after seeing these experiments? And if so, what was it?

A. I thought there was not as much difference between the double and single brakes as I had supposed there was.

2037 Cr.-int. 3. What was there about the experiment that led you to this conclusion?

A. The stops that were made; the points being so near together.

Cr.-int. 4. In any of these trials with the double-brake form or the single-brake form, was the brake so applied as to slide any of the wheels?

A. I didn't notice the first two trials about that. The second trial with the single brake, I think the wheels slid from 10 to 12 inches just as they stopped. Both pairs of wheels slid. On the fourth trial I didn't see them slide at all. I was watching for it, but did not see them slide.

W. H. STEARNS.

Deposition of James B. Clancy.

JAMES B. CLANCY, being called by the defendants, and duly sworn, testified as follows:

Int. 1. What is your name, age, residence, and occupation?

A. My name is James B. Clancy; age, 26; residence, Holyoke, Mass.; and my occupation, a locomotive engineer on the Connecticut River Railroad.

Int. 2. Were you detailed yesterday by M'r Stearns, master mechanic upon that railroad, to run an engine attached to a car, for the purpose of making certain experiments with brakes? If so, what instructions did you receive from M'r Stearns as to what you should do in the furtherance of said experiments?

A. I was so detailed. My instructions were to run to a certain point, to carry the same amount of steam, and to use the same power, to shut off at a designated point, and whistle down brakes at each trial.

Int. 3. What was the number of pounds of steam that your engine carried through the several trials?

A. I carried from 95 to 90 pounds of steam. I started each time with 95, and had 90 when I shut off.

2038 Int. 4. In your judgment, at what speed were you running at the time you shut off and called for the brakes?

A. About 25 miles an hour, I think.

JAMES B. CLANCY.

Deposition of William Carrigan.

WILLIAM CARRIGAN, being called by the defendants and duly sworn, testified as follows:

Int. 1. What is your name, age, residence and occupation?

A. My name is William Carrigan; my age, 31; my residence, Springfield, Mass.; and my occupation, a car-inspector on the Connecticut River Railroad.

Int. 2. Were you present yesterday at an experiment of double and single brakes on the Connecticut River Railroad; if so, how did it come about that you were present?

A. I was present; M'r Robert Hitchcock requested me to go there.

Int. 3. What did you do when you got there?

A. I acted as brakeman on the car.

Int. 4. Before acting as brakeman, what instruction did you receive?

A. To do justice each time I applied the brake.

Int. 5. What did you understand was the import of the instruction "to do justice each time you applied the brake?"

A. To put on my strength to the brake each time.

Int. 6. Did you apply your whole strength on the brake at each of the trials, without reference to whether you were applying the single or the double brake?

A. Yes, sir; I did.

Int. 7. Were you the brakeman who operated the brakes on the same car on a similar trial of double and single brakes made last November, and did you then exert your whole force to stop the car as soon as you could at each trial?

A. I was the brakeman. I did exert all my strength at each trial.

W. CARRIGAN.

2039 *Deposition of Henry A. Wright.*

Int. 1. Will you state your name, age, residence, and occupation?

A. Henry A. Wright; 31 years old; residence, Chicopee; am a farmer at the present time.

Int. 2. Have you been locomotive-engineer upon any road; and if so, upon what road, and when?

A. On the Connecticut River road.

Int. 3. From what time to what time?

A. From about 1864 to the 1st of March, 1872.

Int. 4. What train did you haul on the Connecticut River Railroad while you were engineer, the latter part of the time?

A. The last two or three years I hauled M'r Sampson's train.

Int. 5. Where does that train run from and to?

A. From Springfield to Northampton twice a day, to Holyoke once, and Chicopee Falls once.

Int. 6. In all, how many miles for a day's work?

A. I believe, about 96 miles.

Int. 7. About how many stops are made in that time?

A. There must be forty or fifty stops.

Int 8. Previous, say, to January, 1872, what brake was used on the cars composing that train?

A. When we first had these Wasson cars, it was, I think, what was called the Hodge brake.

Int. 9. Do you recollect thereafter a change being made in the brake on that train of cars already named?

A. I do.

Int. 10. Have you heard the name by which the brake goes?

A. I have been told it is the old Springfield brake.

Int. 11. Please state if you observed any difference in the stopping of the train at the stations after the change was made from the Hodge to the old Springfield brake?

A. When the brake was first put on I couldn't see any difference between the stops. After the brake was somewhat worn I thought it took a little longer to stop than when it was first put on.

2040 Int. 12. Are you in the habit of giving a signal for brakes?

A. Not unless it is necessary. If there is any danger ahead we give a signal. In making the common stops at stations we do not very often, unless the train is going to run by.

Int 13. Are all brakes, the Hodge included among them, liable to be out of order, and not perform one time as well as another?

A. I think they are.

Int. 14. In your judgment, is the Springfield brake a reliable brake when properly taken care of, and the wear of the brake taken up?

A. I think it is, when it is in order.

Cross-examined by M'r Cozzens:

Cr.-int. 1. You have never paid any attention to the subject of brakes, have you?

A. Not that I know of.

Cr.-int. 2. How many cars in M'r Sampson's train that you ran had the Springfield brake on?

A. Generally three cars; that is the usual number.

Cr.-int. 3. Three with the Springfield brake?

A. Three with the Springfield brake.

Cr.-int. 4. Were there any other cars in that train, at any time when the Springfield brake was used, which had the Hodge brake on?

A. Sometimes, not usually.

Cr.-int. 5. About how often do you think there were other cars in that train which had the Hodge brake on?

A. Perhaps not more than once a week. Any time when it was necessary to have more than those three cars, we were in the habit of having other cars, and some of them had the Hodge brake on, I believe.

Cr.-int. 6. You feel pretty sure, do you, that cars with the Hodge brake on did not run in that train more than once a week?

A. I hardly think they did.

Cr.-int. 7. You feel pretty sure of it, do you?

A. As a general thing, I am pretty sure of it.

2041 Redirect:

Int. 15. May not the fourth car that was sometimes put into the train in connection with the three have had the Springfield brake on?

A. I don't know as to that. As to the other cars, besides the three cars, I don't know what brake they did have on.

HENRY A. WRIGHT.

Deposition of William McCormick.

Int. 1. Please state your name, age, residence, and occupation.

A. My name is William McCormick; age, twenty-seven; residence, Springfield; I have been, until quite recently, brakeman on the Connecticut River Railroad.

Int. 2. What is your present occupation?

A. Baggage-master.

Int. 3. How long since you ceased to be brakeman?

A. Two weeks.

Int. 4. How long, prior to becoming baggage-master, two weeks since, have you been brakeman on the Connecticut River Railroad?

A. Five years.

Int. 5. On what trains have you run during that time?

A. For the last three years, nearly, I have run on M'r Sampson's.

Int. 6. Did you run with him up to the time you changed to the position of baggage-master?

A. No, sir; it is some three months since I left his train.

Int. 7. And on to what train did you go as brakeman?

A. The night express.

Int. 8. Where does the night express run?

A. To South Vernon.

Int. 9. Leaves here at what hour?

A. At 8.10.

2042 Int. 10. During the time that you ran as brakeman on said express train, did there come into your train the Tanner brake, as it is shown in "Defendants' Exhibit, large Tanner brake, 123," and, at other times, the old Springfield brake?

A. There did, sir.

Int. 11. It is presumed you had a pretty good opportunity to try the real value of the two brakes running in the rear of the train; what conclusion did you come to as to their comparative merits in taking the slack of the train, or in handling the train, when applying the brakes to bring it to rest?

A. I liked the Springfield brake best.

Int. 12. What reason have you for giving the preference to the Springfield brake?

A. I could check the speed of the train quicker, with less strength.

Int. 13. How with regard to its ease of operation, and the like of that?

A. I did not find any difficulty in operating the brake.

Int. 14. Prior to this time you now speak of, you ran as brakeman on M'r Sampson's train?

A. Yes, sir.

Int. 15. How many cars did you find in that on which the Springfield brake was applied?

A. Usually, three cars.

Int. 16. Ever four?

A. Yes, sir.

Int. 17. Usually, what brake was on the fourth car?

A. We had no particular car. Sometimes the Springfield brake would be on the fourth car; at other times the Hodge brake.

Int. 18. How many brakemen does this train which M'r Sampson runs carry?

A. Two.

Int. 19. And that whether there be three cars or four?

A. Yes, sir.

Int. 20. Is the train sometimes reduced to two, in any of these short trips?

A. It is, sir.

Int. 21. In that case is there more than one brakeman?

2043 A. Both men have to use a brake apiece.

Int. 22. It makes no difference, in running that train, whether it is the Hodge brake or the Springfield?

A. The Springfield brake is usually used.

Int. 23. Whether there were only two cars, or three or four, or more, as a general rule, you relied on no other brake than the Springfield to control the train?

A. No, sir.

Int. 24. About how many miles a day is the work of the train?

A. Ninety-six.

Int. 25. How many stops?

A. Forty-five or six.

Int. 26. Were you brakeman on the same train when they used the Hodge brake?

A. I was, sir.

Int. 27. Had you any particular place then to apply the brakes in approaching a station?

A. I did.

Int. 28. When you came to operate the same train with the Springfield brakes, did you have occasion to change the point at which you applied the brakes?

A. That depended on the speed of the train.

Int. 29. Did it also depend on the speed of the train when you had the Hodge brake on the cars?

A. I did, sir.

Int. 30. In either case?

A. Yes, sir.

Int. 31. What applies to the one applies to the other?

(Counsel for plaintiff objected.)

A. It does.

Cross-examined by M'r Cozzens:

Cr.-int. 1. You profess to compare the Springfield and Tanner brakes in reference to their holding the train; when you did so, how many cars had you in such train with the Tanner brake on them?

2044 A. Never but one.

Cr.-int. 2. How many other cars were there in that train in which the car with the Tanner brake ran?

A. Three others.

Cr.-int. 3. And did those three all have the Springfield brake on?

A. They did, sir.

Cr.-int. 4. Then, what you meant was, that three cars, with the old Springfield brake on, would hold the train better than one car, with the Tanner brake on, was it? or, if not that, what did you mean?

A. We take the slack of the train with the rear car, whatever car happens to be there, whichever brake happens to be there, and stop it with the others when we want to stop.

Cr.-int. 5. Do you mean, then, that when a car, with the Springfield brake on it, was in the rear of the train, you could take the slack of the train better than when a car, with the Tanner brake on it, was in the rear of the train?

A. I do, sir.

Cr.-int. 6. With which could you take the slack of the train best—the rear car with the Springfield brake, or the rear car with the Hodge brake?

A. The Springfield brake, when I used that, was better than the Hodge brake.

Cr.-int. 7. How many times did any cars, having the Hodge brake on, run in M'r Sampson's train, with any of those cars which had the Springfield brake on them?

A. I don't think more than once a week. I don't think it averaged more than that.

Cr.-int. 8. You were present and heard what the last witness said about once a week, didn't you?

A. I did, sir.

Cr.-int. 9. Do you feel pretty sure it did not average more than once a week?

A. I think it did not.

Cr.-int. 10. You feel positive of it, do you?

A. Might be more, and might not. I can't tell you exactly.

2045 Cr.-int. 11. Do you really know how often it was?

A. I do not, sir.

WILLIAM McCORMICK.

Deposition of Henry F. Sampson.

Int. 1. Will you state your name, age, residence, and occupation?

A. Henry F. Sampson; age, 37; residence, Springfield; occupation, conductor on the Connecticut River Railroad.

Int. 2. How long have you been conductor on the Connecticut River Railroad?

A. Fifteen years.

Int. 3. What train are you now running?

A. I am running what we term the local trains—short trains.

Int. 4. How long have you run that train?

A. I have always run them, for a regular thing.

Int. 5. How many cars compose it, as a general thing?

A. Three cars.

Int. 6. Do you ever have occasion to add to that number?

A. Very seldom.

Int. 7. How often?

A. Perhaps once a week—on Saturday. No other day, unless it is some holiday. I don't think it will average that.

Int. 8. Inasmuch as you have four cars with the Springfield brakes on them, may not the extra car be one with the Springfield brake as well as with the Hodge brake?

A. Yes, sir; it is liable to be that car as much as another.

Int. 9. May be that car as well as another?

A. Yes, sir. It is just as the cars happen to be in the yard.

Int. 10. And it may be the hind car, with the Tanner brake on it?

A. Yes, sir.

Int. 11. From this point to what points do you run this train, and how often?

2046 A. Twice a day to Northampton, 17 miles; once to Holyoke, 8 miles; and once to Chicopee Falls, 6 miles; and return, all of them.

Int. 12. At the time of the change of brakes on your train from the Hodge brake to the Springfield brake, were you made acquainted with the fact?

A. I was not.

Int. 13. How long did you run the train before you became aware of the fact of a change?

A. It might have been two or three days; I can't say as to the time exactly.

Int. 14. From the time that you did note the change, did you or not discover any difference in the stopping of the train at stations?

A. I did not discover any difference.

Int. 15. Please state whether you have discovered such difference since that time.

A. I have not.

Int. 16. Have you had any occasion to make any complaint to the engineer or brakeman for letting the train run by the stations since the change was made?

A. No, sir.

Int. 17. Ordinarily, then, I take it that you make the stops as well with one as with the other?

A. The train is handled just as well; I can't see any difference.

Int. 18. Have you, since the Springfield brake was put on to the cars of your train, had occasion to take the time required by the brakeman to bring it to a stop at the stations?

A. From forty to fifty seconds. I have timed it at different times with a wet rail and dry rail both.

Int. 19. What difference did you discover between a wet rail and dry rail in stopping the train?

A. Five and ten seconds. The engineer, of course, would give us occasionally sand, if it was a wet rail, and we were going by a station.

Int. 20. The sprinkling of sand from the sand-box on a wet rail will cause the wheels, as they go over it, to adhere as well as on a dry rail?

2047 A. Yes, sir; just as well.

Int. 21. Has there been any running by stations in consequence of the insufficiency of brakes?

A. No, sir.

Int. 22. Is your train still equipped with the Springfield brake?

A. It is; three cars.

Int. 23. Have you heard any complaint of the brakes not holding as well in running from a straight track to a curve, or from a curve to a straight track?

A. No, sir.

Int. 24. Has any complaint come from any quarter of the chains overlapping each other, thus shutting off the power from the wheels and rendering the brake inoperative?

A. No, sir.

Cross-examined by M'r Cozzens:

Cr.-int. 1. How many times since the Springfield brakes have been on your train have there been other cars in it having the Hodge brake on?

A. I don't think it has averaged once a week. Possibly on Saturday. Saturday is our heavy day, and we have an extra car on occasionally.

Cr.-int. 2. Would the occasions when, on Saturday, a car or cars with the Hodge brake on might be on that train be because you had to use more than three cars?

A. Yes, sir.

Cr.-int. 3. Did you see your train when it went out this morning?

A. I have not run to-day.

Cr.-int. 4. Did you see it when it came in this afternoon?

A. Yes; I saw the engine as I went down street a moment ago; that is all.

Cr.-int. 5. You didn't see the train?

A. No, sir.

Redirect:

Int. 25. Please state, if you know, what is the radius of the curve over which you have to run in coming into the station under the brakes at Springfield.

2048 A. I don't know. I have heard it stated, but I don't recollect.

Int. 26. Are the brakes applied to the cars of the train in passing that curve in coming in?

A. Yes, sir.

Int. 27. Have you ever discovered that the brakes either tightened or loosened in consequence of running on to that curve?

A. No, sir.

Int. 28. Do you or not consider that you are taking any extra responsibility in running a train the cars of which are equipped wih the Springfield brake instead of the Hodge brake?

A. No, sir. These same cars were fitted up five months with the Hodge brake, if you recollect, and then fitted up afterwards, about November, I think, with the Springfield brake. I could not see any difference in stopping the train. We ran from June to that time with the Hodge brake.

HENRY F. SAMPSON.

Deposition of Only L. Smith.

Int. 1. Please state your name, age, residence, and occupation.

A. My name is Only L. Smith; I am sixty years of age; residence, Providence, R. I.; occupation, car-builder on the Providence and Worcester Railroad.

Int. 2. Have you charge of the car department of that road?

A. I have.

Int. 3. And for how many years?

A. Twenty-five years, this month.

Int. 4. What brakes are in use on the passenger cars of your road at the present time?

A. The Hodge.

Int. 5. What brakes were in use on said cars before you adopted the Hodge brake?

2049 A. The Tanner; on the passenger cars.

Int. 6. Did you, some five or six months ago, restore the Tanner brake on one of the cars of your road; and, if so, for what purpose?

A. I restored the Tanner brake.

Int. 7. And for what purpose did you understand the restoration was required.

A. Well, I can't answer that; for I had no explanation of it, as I know of, at that time. I don't know what it was done for.

Int. 8. At the same time you restored the Tanner brake to a car on your road, what other brake did you apply to another car?

A. What is called the old Springfield brake.

Int. 9. Were the cars to which the old Springfield brake and Tanner brake were applied coupled together and run in the same train?

A. They were.

Int. 10. Please state what your instructions were in the application of the Tanner brake to a car, and of the old Springfield brake to another car, on the same road.

A. My instructions were to restore the Tanner precisely as it was run on the road when we used the Tanner. The other brake was applied according to a model shown by M'r Whipple.

Int. 11. Please state how you applied the brake as to the levers, and as to how you applied the chains to the levers which connect with the windlass staff.

A. The levers that were in the truck were not changed at all. I put two more in, and then crossed the rod, both top and bottom. These two added levers were placed at the ends of the trucks farthest from the windlasses. I connected one windlass with two chains, and the other with one chain.

Int. 12. What were the numbers of the cars to which the Tanner and Springfield brakes were applied?

A. No. 24 and No. 26.

Int. 13. Were those cars coupled together and put into the same train?

A. They were.

2050 Int. 14. How long were they run in that train?

A. No. 24 car was put on December 22; No. 26, December 28. No. 26 had the Tanner brake; No. 24, the Springfield. The Springfield brake was taken off the 22d of February, the Tanner the 24th.

Int. 15. What complaint, if any, came to you from the brakemen as to the working of the two brakes on their cars, respectively?

A. They complained that they could not hold their train with the new brakes I had just put on.

Int. 16. What disposal was finally made of the aforesaid brakes?

A. They were finally taken off by the order of the superintendent.

Int. 17. What, thereafter, was done with reference to either or both of those brakes?

A. The Tanner brake was put on a second time, March 20.

Int. 18. Under what circumstances?

A. By order of M'r Sayles.

Int. 19. How long did it continue on; and what disposal was made of the brake put on by order of M'r Sayles?

A. It was taken off the 4th of April.

Cross-examined by M'r Cozzens:

Cr-int. 1. How well did the Tanner brake work after it was put on in the way requested by M'r Sayles?

A. I have no means of knowing how it worked on the road,—not personally, from my own observation. I did not go on the train at all, or on the cars. I never tried the brake after it went out of the shop, with one exception.

Cr.-int. 2. What was the one exception?

A. That was when M'r Sayles and myself took a car with the Tanner brake, and one with the Hodge, to test the power of the two brakes in one position. That was on a curve.

Cr.-int. 3. How well did the Tanner brake work on that occasion ?

2051 A. Well, I will state that we took those cars out of the car-house; we had an engine come and take hold of them, and haul them out in front of the house on a curve. The first car had the Tanner brake on. The engineer pulled that car out until I ordered him to stop. I stepped up on to the foot-board and turned the brake with all the power that I had; stepped off the foot-board and gave a motion to the engineer to go ahead. He started the car about the length of it, the brake holding well. I got up on to the platform and let off this brake, hauled down the other car to the place, as near as we could, where this car with the Tanner brake started. I got up and screwed the Hodge windlass in the same manner, and gave orders for the engine to move; and it was my opinion that the Tanner brake, or the car that had the Tanner brake on, held better than the other. I formed that opinion from the motion and power applied to the engine to start it.

Cr.-int. 4. When you applied the Tanner brake the first time on the Providence and Worcester Railroad, as you have stated, who gave you instructions about how to apply it?

A. The instructions came from M'r Whipple, and were to put the Tanner brake on precisely as we used it. I had one of the centre levers in the blacksmith's shop, and I used one of the same levers that we had before, and I applied it just as near as I could.

Cr.-int. 5. Now please state in what way it was applied this first time?

A. Why, it was applied by a centre lever about four feet in length, with four rods at the ends.

Cr.-int. 6. Look at "Defendants' Exhibit, large Tanner brake, 123," now present, and say if it was like that, so far as the connections with with the centre lever are concerned?

A. Yes, sir; that is just the same.

Cr.-int. 7. Now, how was it applied the second time, as M'r Sayles requested you to apply it?

A. In each arm of the centre lever there was a hole drilled about nine inches from the end of the lever, and the link rods running to the respective truck levers were hooked into those holes.

2052 Cr.-int. 8. Was any change made in the proportions of the respective arms of the truck levers when the Tanner brake was applied this second time, as compared with what they were when applied the first time under M'r Whipple's directions?

A. There were no changes made in the truck levers.

Cr.-int. 9. In the case of the Springfield form of brake, where there are two chains winding around the same windlass staff, suppose that one of the chains, in being wound up, should catch around the eye of the windlass, and wind spirally round the windlass shaft, while the other chain on the same windlass wound straight, would the brake then brake alike on both trucks?

A. I should not think it would.

Cr.-int. 10. In your judgment, as a practical car builder, if a brake was liable to do that thing frequently, would it be an efficient brake for braking upon both ends of the car for passenger trains?

A. You are speaking now in regard to the old Springfield brake, as attached here; it would not be equal; it would be unequal.

Cr.-int. 11. That you have answered. The question is a step further than that?

A. I pretend to say that this chain will take up faster than that one. If it does, it don't wind up equal. If this chain laps under the eye, and t has the same diameter to wind on that this has, they will both wind up together; but if you are going to bring that eye there and this up further, an inch nearer the centre of your windlass, then one gains on the other.

Cr.-int. 12. If such a brake as this two chain Springfield brake would do that,—that is, act unequally on the two trucks,—would it be a reliable brake for acting on the two trucks?

A. It would not be reliable to act equally well; still, it would act. But one truck would get the advantage of the other,—have more power. You may stop your train. You might rely on it to stop at a station, but perhaps not as readily as you would if you had the power applied equally.

Cr.-int. 13. Until you know how much the inequality is, of course you can't tell?

2053 A. That is the matter.

Cr.-int. 14. Suppose this two chain Springfield brake had the length of the short rod and chain fourteen inches from the windlass shaft to the top of the truck lever, would, in your judgment, that be a safe brake to use for a passenger car?

A. Oh, yes. "Safe?" Yes, I think it would be safe.

Cr.-int. 15. Would you use it, if you could avoid it?

A. No, sir, I should not use it. I don't think I should long; because it wouldn't keep itself in repair, and I don't believe I should want to.

Redirect:

Int. 20. Was the experiment which you made with the Tanner brake and the Hodge brake, as you have already described, of such a character as led you to the conclusion that the Tanner brake was better than the Hodge brake for passenger cars? and, if not, why not?

A. No, sir; it don't wear the brake-shoes as equal. You can't adjust it as you can the Hodge brake.

Int. 21. Look at "Defendants' Exhibit, large Tanner brake, 123," and state, if the shoes are well worn on one truck and new shoes are on the other, whether there would be equality between the two trucks in applying power from the windlass to both trucks.

A. I say, equalize the shoes,—that don't mean unequal, that means equal,—and the power will be just the same.

Int. 22. But supposing they are unequal in thickness on the trucks?

A. They cannot be unequal; they have got nothing to make them unequal, unless one head is softer than the other; and then keep them equal by repairs; follow them up, keep them equal, and I cannot see why you cannot hold just as well with the Tanner brake as you can with the Hodge.

Int. 23. Assume that the car has come to shoeing in both trucks of the Tanner brake, and you leave the old shoes on one truck, and put new shoes on the other truck, and then put the car on the road, will the power be equal between the two trucks?

2054 A. Yes, sir; it will be equal, if they are properly adjusted, just as we would expect any man who does that business would have them.

Int. 24. Will they continue to be equal?

A. No; nor under any other circumstances. I don't care what truck, nor what brake you put on, you can't wear them equally. There are many reasons for it.

ONLY L. SMITH.

Deposition of V. D. Perry.

Int. 1. State your name, age, residence, and occupation.

A. V. D. Perry. Age 49. Residence Hartford. Occupation, master car-builder.

Int. 2. How long have you been?

A. I have been with the Hartford, Providence and Fishkill road 18 years.

Int. 3. How long have you been master car-builder on that road?

A. Seventeen years and a half.

Int. 4. Please state if you have at any time applied what is called the old Springfield brake to a car on that road? And if so, state how you placed the levers in the truck.

A. We applied a brake of that kind some time in February—perhaps the middle of February, 1872. We left the two brake-levers in the truck, and put in two more, and connected them on the windlass with the two chains at each end.

Int. 5. Did you put this car into a train?

A. We put it into one of our through trains, which we are running 122 miles a day.

Int. 6. What other brakes are in use on your road?

A. We have the Tanner and the Hodge brake.

Int. 7. To what extent are you using the Hodge brake?

A. We have got the Hodge brake on to 32 passenger-cars, and about 12 mail-cars. We are using the Tanner brake still on four or five short baggage-cars. We have not had time to change them.

2055 Int. 8. What brake did you use on passenger-cars previously to adopting the Hodge brake?

A. We used the Tanner brake.

Int. 9. How long is it since you adopted the Hodge brake?

A. I should think eight or ten months.

Int. 10. Then you are well acquainted with the operation of the Tanner brake

A. I am.

Int. 11. How did the old Springfield brake hold the car, as compared with the Tanner brake, on a car of like weight and construction?

A. As regards that, I never heard any complaint about the Springfield brake?

Int. 12. Have you been out on the road to see the operation of the Springfield brake on the car to which you applied it?

A. Never but once. I was obliged to go to Providence, and I went down on the train where this car was running, and watched the operation of it, because it was new to me, and I was very much pleased with the power of it. I did not notice but what it took up the slack of the train. From Hartford to Vernon, 15 miles, we run a car out behind this car; there, the other car is taken off, and this car is the rear car, from there to Providence, about 75 miles; and going down the mountain, we have to use the brakes a good deal. We have a steep grade for a number of miles, and it requires good brakes to hold the train in.

Int. 13. You depended upon this brake attached to the rear car?

A. We always do, to take the slack of the train, in the first place. That is rulable everywhere, I believe.

Int. 14. Who was brakeman on the train in which this car ran?

A. M'r Lewis has had more to do with the brake than anybody else. We changed the brake at Hartford. The man there runs 130 miles. M'r Lewis has run it 90 miles a day. That has been the regular run with him.

Int. 15. What size windlass wheel do you run on your passenger-cars with the Hodge or Tanner brake?

2056 A. We have used, for a great many years, a 16-inch wheel.

Int. 16. Do you make any difference in the size of the wheel, upon freight and passenger cars?

A. We have always used a 12-inch wheel on our freight cars, except that, on our coal cars, as we call them, we put a 10-inch wheel.

Int. 17. Why do you use a 12-inch wheel on a freight car, single brake, and a 16-inch wheel on a passenger-car, double brake?

A. In order to regulate the power. We spoil wheels enough, we think, with a 12-inch brake-wheel, without putting on a 16-inch.

Int. 18. Can a brakeman apply the same power to a double brake, through a 16-inch wheel, that he can on a single brake, through a 12-inch wheel?

A. I suppose he could, just about the same. That is one reason why we adopted two sizes of wheels.

Cross-examined by M'r Cozzens:

Cr.-int. 1. What are the lengths of the respective arms of the brake-levers, in the Springfield brake, as you have it on your road?

A. The long arms, 29 inches; the short arms, 7 inches.

Cr.-int. 2. What is the length of the short chains and rods from windlass-staff to top of brake-levers?

A. I should say the chain and rod would be about nine feet long.

Cr.-int. 3. Are the brake-levers to which these short chains and rods run, placed at the ends of the trucks farthest from the windlass?

A. They are.

Cr.-int. 4. What is the length of the long chains and rods, from windlass-shafts to top of brake-levers?

A. It must be 44 feet.

Cr.-int. 5. How long are the cars?

A. Our cars are about 43 feet, from outside to outside.

Cr.-int. 6. Take it from the outside to outside of platforms?

A. 49 feet; that is, to the brake-staff.

2057 Cr.-int. 7. In the Springfield brake, as you have it on your road, which chain and rod are uppermost—the short one, or the long one?

A. The long one.

Cr.-int. 8. How many cars are there usually run in this train in which you say this car with the Springfield brake on is?

A. Five or six. We run unequally. Some days we run more, and some less; but never less than five.

Cr.-int. 9. On the other cars, than the one having the Springfield brake, what brakes are used?

A. They have the Hodge brake.

Cr.-int. 10. How long had you used the Tanner brake on the Providence, Hartford and Fishkill Railroad, prior to your recent change to the Hodge brake?

A. Sixteen years, sir.

Cr.-int. 11. This grade, of which you speak, over the mountains, was the same during all the time you used the Tanner brake that it is now, was it?

A. The same; but our trains were not near so heavy.

Cr.-int. 12. Is it within your knowledge, that there was a suit brought by M'r Hodge, the patentee of the Hodge brake, against the Hartford, Providence and Fishkill road, for infringement of the Hodge patent, by using the Hodge brake?

A. Yes.

Cr.-int. 13. You were using the Hodge brake at that time?

A. We bought six cars with that brake upon them. They came there without any specification in regard to the brake; and, when we received them, they had the Hodge brake on. I suppose our superintendent did not know anything about the patent, and we run them for some months; but, as soon as we were sued by M'r Hodge for using his brake, I received orders from the superintendent to remove them, and did so.

Cr.-int. 14. What brake did you put on said six cars when you removed the Hodge brake?

A. Put on the Tanner brake.

2058 Cr.-int. 15. Did you have the Tanner brake on other cars besides these six cars?

A. We had the Tanner brake on the other cars.

Cr.-int. 16. And you continued to use the Tanner brake on all your passenger cars until you recently made the change, since the Hodge patent expired?

A. Yes, sir; we have talked a great deal about changing for the last six or seven years; but I never had any orders to change until since the Hodge patent expired.

Redirect:

Int. 19. Setting aside the Hodge brake, from what you know of the Tanner brake and the Springfield brake, if you were obliged to use one or the other, which would you choose?

A. I believe one is as good as the other, properly adjusted.

Int. 20. On what road in New England besides yours is the Tanner brake in use, within your acquaintance?

A. I don't know of any, at the present time.

Int. 21. And it is not in use on your road, except on a few cars?

A. I have left it on some little short cars—we call them 30-foot cars. They have not been run much. We have not had time to change the brakes on those cars. They are used only occasionally. I had orders to change everything, and intend to do so as soon as we can get time.

Int. 22. When this Springfield brake was put upon a car on your road, what did you understand to be the object in view in so doing? (Counsel for plaintiff objected.) Or, in other words, what did M'r Whipple state to you was the object?

A. To test its effectiveness and efficiency, as compared with the Tanner brake. That is what I understood to be the object.

Int. 23. Did you come to the conclusion that one was as effective as the other?

A. I did. There was no reason to think otherwise from our trial.

2059 Recross by M'r Cozzens:

Cr.-int. 17. Did you ever know the Springfield brake to be used regularly on any railroad in the United States, previous to the last year or so?

A. I never did.

Cr.-int. 18. Are you able to state what brake was used upon the New Haven, Hartford and Springfield Railroad down to the time of the introduction of the Hodge brake? If so, what brake was it?

A. I think it was the Tanner brake.

Redirect:

Int. 24. M'r Lewis has testified, in his cross-examination in this case, that the old Springfield brake, applied to a car of the Providence, Hartford and Fishkill Railroad, was taken off three or four weeks ago. Will you please state, first, what the object was of putting the brake on; and secondly, why was said brake taken off?

A. The object was to test the comparative merits of the old Springfield and Tanner brakes in the matter of holding the car. I looked after the brake thoroughly, during the time it was on that car. I satisfied myself, from close observation, and from statements from the brakeman, M'r Lewis, that it was as reliable as the Tanner brake, when in order. After using it four months, I ordered it off. It is a car we have always used regularly. It came in to repair a wheel, and we took the brake off and put the same Hodge brake on we took off.

Int. 25. Had there been no Hodge brake in use on your road, would you, or would you not, have taken off the Springfield brake for the purpose of putting on the Tanner brake?

(Objected to by M'r Sayles.)

A. No.

Int. 26. Your preference, then, as between the two brakes already named, I take it, is for the Hodge brake?

(Objected to.)

2060 A. It is.

Int. 27. What reason can you assign for your preference?

(Objected to.)

A. I should say, increased amount of leverage, giving more power, and also the self-adjusting qualities of the Hodge brake.

Cross-examined by complainant:

Cr.-int. 17. I think you stated, a few days ago, that the Tanner brake was applied to your cars same as "Defendants' Exhibit, large Tanner brake, 123."

A. I did.

Cr.-int. 18. If you had wished to increase your leverage or power, could you not have done so with the Tanner brake by attaching the rod running from the truck-lever to a point on the centre lever, between the outer end and the centre of said centre lever?

A. That would naturally increase the power; to what extent I can't say. I never tried it.

Cr.-int. 19. Do you build passenger cars for your road?

A. We do.

Cr.-int. 20. Will you please tell us how you construct the swing or centre beam of the trucks of your passenger cars and centre plates? How much play do they have lengthwise of the car?

A. We never give more than $\frac{1}{16}$ of an inch. We get cast plates about 6 inches square, and have them chilled and fastened to the centre-beams of the truck, also to the swing beam, and give a space of $\frac{1}{16}$ of an inch between the two. The centre plates are closely fitted, so that there is no play in them at all when they are new.

Cr.-int. 21. How much play will there be in them after they have run a year or so?

A. Not to exceed $\frac{1}{4}$ of an inch.

Cr.-int. 22. Do you think there was ever play enough in those parts of your passenger and baggage cars, to affect the practical working of any brakes you have used since you have been on that road?

2061 A. I do not.

Cr.-int. 23. Was the Springfield brake attached to the car spoken of by you on your road, as shown by Complainant's Accounting Exhibit, No. 2 (J. M. W. Y.)?

A. It was.

Adjourned.

Redirect:

Int. 28. Since your examination, has there a test been made on certain cars of the Hartford, Providence and Fishkill Railroad, to ascertain how much longitudinal motion there is between the body of the car and the truck? If so, upon what cars was the test made, by whom, and with what result?

A. There has been such a test made upon cars No's 5, 26, 17, 28, and 7, just as they were found in a train made up. They were passenger cars and a baggage-car, and all had the Hodge brake on. The test was made by making a centre mark on the body of the cars, and also on the truck-frame, and then barring the other truck ahead as far as it would go. This test was made by F. D. Adams, master car-builder of the Boston and Albany Railroad, Robert Hitchcock, master car-builder on the Connecticut River Railroad, and H. M. Perry, foreman in the car dep't of the H. P. and F. Railroad. Car No. 5 showed a longitudinal motion of ¾ of an inch; No. 26, ¾ of an inch; No. 17, ¾ of an inch; No. 28, 1 inch; No. 7, 1 inch.

Int. 29. What is the width of the bolster or swing-beam on the trucks, of the cars referred to in your last answer?

A. Twelve inches.

Int. 30. Prior to adopting the 12-inch bolster, what was the width of the bolster used?

A. Eight inches.

Int. 31. How long since did you use the 8-inch bolster, as a general thing?

A. We used it almost altogether up to three years ago; that is to say, up to the fall of 1869.

Int. 32. Which bolster gives the most longitudinal motion between the trucks and the car body?

2062 A. I should say the 8-inch, as it is more liable to tip when the chafer or friction-plates become worn.

Int. 33. What brake did you use on your passenger-cars when the 8-inch bolster was in use?

A. The Tanner brake.

Int. 34. When you used the Tanner brake, what did you frequently observe as to the sliding of wheels on the application of the brake?

A. I have noticed it was almost always the pair of wheels that was farthest from the brakeman that slid when the car was in the rear of the train.

Cross-examination by M'r S. D. Cozzens:

Cr.-int. 24. When you say the pair of wheels farthest from the brakeman, do you mean the pair of wheels at the farthest end of the car from the brakeman, or the pair of wheels at the farthest end of the truck next to the brakeman?

A. At the farthest end of the car from the brakeman, I mean, as stated.

Cr.-int. 25. About what is the average weight of the cars running in passenger-trains upon the Hart., Prov. and Fish. Railroad at the present time?

A. 16 tons.

Cr.-int. 26. For about how long have they been of this average weight?

A. Ever since the railroad has been in operation.

Cr.-int. 27. What is the weight of the heaviest cars on your road now running in passenger-trains?

A. 17 tons.

Cr.-int. 28. About what proportion of the whole number of cars running in passenger-trains upon your road are of this weight?

A. Just about one-half.

Cr.-int. 29. For about how long a time have you had that proportion of your cars of the weight of 17 tons?

A. About four years.

Cr.-int. 30. Previous to about four years ago, what proportion of your cars running in passenger-trains would weigh 17 tons?

2063 A. None of them.

Cr.-int. 31. Have you had no cars running in passenger-trains upon your road weighing 17 tons, except since four years ago?

A. I do not think we have.

Cr.-int. 32. About what is the average number of cars in passenger-trains upon your road at the present time?

A. Our trains will average four cars to the train; we run some heavier and some lighter trains.

Cr.-int. 33. What is the number of cars in your heaviest trains in your regular business?

A. Seven cars.

Cr.-int. 34. Between what points do these trains of seven cars run?

A. Hartford and Willimantic; at Willimantic we take off generally two cars, and run to Providence with five cars.

Cr.-int. 35. About how long have you run such trains as these; that is, seven cars to Willimantic and five to Providence?

A. For the last four years.

Cr.-int. 36. Now, excluding these trains just spoken of, what is the average number of cars to a passenger-train upon your road at the present time?

A. Four cars.

Cr.-int. 37. About how long has that been the average number on such trains?

A. Four years.

Cr.-int. 38. On the through passenger-trains at the present time, from Providence to Hartford, is the number of cars the same as from Hartford to Providence?

A. Yes; it is the same train with the same number of cars.

Cr.-int. 39. About how long has this been so?

A. Four years.

Cr.-int. 40. On page 221 of Defendants' Accounting Record you make this answer: "We spoil wheels enough, we think, with a 12-inch brake-wheel, without putting on a 16-inch." You meant, didn't you, spoiling them by the wearing due to sliding them?

2064 A. I did.

Cr.-int. 41. In your recall by the defendants, on the 15th of August, 1872, you stated that you "satisfied yourself, from close observation and statements of brakeman, M'r Lewis, that it (the Springfield brake) was as reliable as the Tanner brake, when in order." What portion of this conclusion was given by you from your own personal observation?

A. I made up my mind by observations in riding upon the car on various occasions. I went to Providence and back twice, and to New Britain several times.

Cr.-int. 42. At these times, how many other cars were there in the trains upon which you were?

A. At no time less than four.

Cr.-int. 43. Were Hodge brakes on all the cars of these trains except the one car which had on the Springfield brake?

A. They were.

Cr.-int. 44. How many brakemen were on these trains?

A. Two.

Cr.-int. 45. Were the Hodge brakes used on these trains when you were on them?

A. Of course they were.

V. D. PERRY.

The three following depositions were taken at Springfield, Mass., April 9 and 10, 1873:

Deposition of S. L. F. Deyo.

Direct examination:

Int. 1. What is your name, age, residence, and occupation?

A. Name, S. L. F. Deyo; age, 22 years; residence, New York City; occupation, civil engineer.

Int. 2. Have you in your possession drawings of the curves which lead
from Fourth avenue, New York City, into the yard of the old
2065 New York and New Haven depot, between 26th and 27th streets,
over which the cars of the New York and New Haven Company
run, prior to moving to the Grand Central Depot at 42d street?

A. I have.

Int. 3. By whom were said drawings executed and the date thereof?

A. Executed by J. Schuyler, and dated March 4, 1857.

Int. 4. Have you made tracings from these drawings? It so, please state the scale of said tracings.

A. I have. The scale is one inch equal to one foot.

Int. 5. You will now please look at "Defendants' Exhibit, 27th street curves," and state whether they are an exact copy of the original drawings by said Schuyler, except that they are enlarged?

A. They are.

Int. 6. Were said tracings made from said drawings by yourself?

A. They were.

Int. 7. Please state the radii of the curves so drawn and shown by said "Exhibit, 27th s't curves."

A. Fifty feet to the inner edge of the inside rails.

Cross-examination by S. D. Cozzens:

Cr.-int. 1. Did you see M'r Schuyler make the original from which this tracing has been made?

A. No; I did not.

Cr.-int. 2. You yourself don't know anything about the accuracy of the original drawing, do you?

A. No.

Cr.-int. 3. You made no measurements or surveys yourself before making this tracing, did you?

A. I did.

Cr.-int. 4. What did you measure or survey?

A. The curves as they now lie.

Cr.-int. 5. For what purpose did you measure them?

A. To get notes for a map.

Cr.-int. 6. Had this anything to do with this tracing?

A. I took the survey before the original drawing was found. After the drawing was found I made the tracing from it.

2066 Cr.-int. 7. Had you completed your surveys before the original drawing was found?

A. Yes.

Cr.-int. 8. How nearly do your surveys so made, correspond with the original drawing?

A. They correspond except in two respects: one is the distance between the tracks on the Avenue. In the original drawing that is six feet; by my survey it is five feet and three inches, so nearly as I can remember. The other is as to the radius. In the original drawing the radius is shown as being fifty feet to the inner edge of the inside rail of each track; by my survey I made it fifty feet to a line drawn equidistant between the rails of each track.

Cr.-int. 9. And I understand you that the tracing is in these respects like the original drawing, and not like your surveys?

A. Yes.

Cr.-int. 10. What do you mean by the rectangular lines marked "pier" in your tracing?

A. It refers to the "pier" that supports the iron gates of the yard at 27th st.

Cr.-int. 11. Also please state what the rectangular lines marked in length 25 f't refer to?

A. To 27th st. depot building.

Redirect examination:

Int. 8. What, from your own knowledge, is the radius of the several curves traced on said exhibit?

A. As the curves are now, they are fifty feet to a centre line between the rails of each track; and, what is said of one track may be said of all the curves intended to be represented by said exhibit.

S. L. F. DEYO.

Deposition of Henry Wolfe.

Int. 1. What is your name, age, residence and occupation?

A. Name is Henry Wolfe; age, 49 years; residence, New York
2067 City, and occupation, baggage-master for the New York, New Haven and Hartford Railroad at the Grand Central depot in New York.

Int. 2. How long have you been in the employ of said company, at what places, and in what capacities?

A. I have been in the employ of the New York and New Haven Company in the neighborhood of 19 years; at Canal st. and 27th st. in New York City; and 42d st. at Grand Central depot, in said city. At Canal st. I was assistant station baggage master; at 27th st. I was depot master, and for a short time before I left Canal st.; and now I am baggage-master at the Grand Central depot.

Int. 3. Have you knowledge of the curves in the track of the said New Haven Railroad leading from 4th Avenue into the yard at 27th st.

A. Yes.

Int. 4. Are the curves, as represented in "Exhibit 27th St. Curves," from your best recollection correct as seen in said exhibit?

A. Yes.

Int. 5. Were there other curves as sharp as those seen in said exhibit over which the cars of said New Haven road were hauled to Canal st.? If so, please state where they were located?

A. I think there was one on the corner Bowery and Broome sts. simi lar to it; another on the corner of Broome and Centre sts.; another corner Centre and Canal sts. On the return to 4th Avenue there was one on the corner Grand and Centre sts., and another on the corner of Grand and the Bowery. Making five curves in all.

Int. 6. Do the above named streets cross each other nearly or quite at right angles?

A. Yes, the same as seen on said exhibit at 27th st. and 4th avenue.

Int. 7. Did or not all the passenger cars including baggage and express of said New York and New Haven Railroad pass over these curves to Canal-st. depot?

A. Yes.

Int. 8. What other passenger cars besides those above named passed over said curves?

2068 A. New Haven, Hartford and Springfield cars and Boston and New York express line cars.

Int. 9. During what years did said cars, as above named, pass over said curve to Canal street, and return?

A. In 1855, 1856, and a part of 1857.

Int. 10. When did said cars begin to run into the yard at Twenty-seventh street over the curves represented in said Exhibit?

A. In July, 1857, and continued to run up to November, 1872, when they began to stop at the Grand Central depot at Forty-second street.

Cross-examination:

Cr.-int. 1. Did you ever measure any of the curves you have testified about to ascertain their radii?

A. No.

Cr.-int. 2. Then when you say that the curves at the Twenty-seventh street correspond with the Exhibit Twenty-seventh street curves, you are judging by your eye, are you not?

A. Yes.

Cr.-int. 3. And when you say that the other curves in New York City, of which you spoke, are, you think, as sharp as the Twenty-seventh street curves, you are also judging only by your eye, are you?

A. Yes.

Redirect examination:

Int. 11. From your personal inspection of the several curves of which you have testified, what is your judgment as to whether they are like or unlike as to the point of sharpness of curvature?

A. About the same thing, I should say.

HENRY WOLFE.

Deposition of John A. Hearn.

Int. 1. What is your name, age, residence, occupation, and by whom employed?

2069 A. My name is John A. Hearn; age, 30 years; residence, Springfield, Mass.; by occupation, mechanic, and employed by the Connecticut River Railroad Company.

Int. 2. Do you work in both wood and iron?

A. Yes.

Int. 3. Look at "Complainants' Accounting Exhibit, Hervey Waters' Radius Diagram, Sheet No. 2," and state whether you have made a model track of said diagram on the same scale and curve as the tracing therein shown?

A. Yes.

Int. 4. What is the scale and what the radii of the curves represented both in the diagram and model?

A. The scale is one inch to one foot, and the radii 800 f't.

Int. 5. Is there a reverse curve of the same radius shown in the model track?

A. There is.

Int. 6. How is said model track marked?

A. Marked in white paint, "800 f't radius."

Int. 7. Look at "Defendants' Exhibit, Twenty-seventh street curves," and state whether you have made a model track of said curves, and, if so, please state what is the scale on which it is made, and what are the radii, and how is said model track marked?

A. I have made such model track; the scale is one inch to one foot; the radii are 50 f't; the model track is marked "50 f't radius," in white paint.

Int. 8. Look at "Defendants' Exhibit, Springfield brake, No. 1," and state the scale on which said Exhibit is constructed in all its parts, including the brake attached thereto, and state what car on the Boston and Albany Railroad you took the measurements from; and also state whether the dimensions of the brake on said car are correctly represented in said Exhibit?

A. The scale is one inch to one foot. I took the measurements of all parts of the Exhibit except the brake from car "No. 136," and the brakes from car "No. 123." The bodies and trucks of the two cars are the same. The dimensions of the brake on said car "No. 123" are correctly represented in said Exhibit.

2070 Int. 9. Look at "Defendants' Exhibit, Springfield brake, No. 2," and state the scale on which said exhibit is constructed, and from what car you took the measurements.

A. The scale is one inch to one foot. I took the measurements from car "T" of the Connecticut River Railroad.

Int. 10. Look at "Defendants' Exhibit, Springfield brake, No. 3," and state the scale on which said exhibit is constructed, and the car from which you took the measurements of the body and trucks.

A. The scale is one inch to one foot. I took the measurements from car "No. 26" of the New York and Boston express line. The brake on said exhibit I put on according to drawings furnished me by M'r Robert Hitchcock, master car-builder of Connecticut River Railroad Company. The parts of the brake are intended to be on the same scale of one inch to a foot, as near as they conveniently could be.

Int. 11. Look at "Defendants' Exhibit, Hodge brake," and state from what car you took the dimensions, and the scale observed in the construction of said exhibit.

A. I took the measurements from the same car, "No. 26," above mentioned. The scale is one inch to one foot.

Int. 12. Look at "Defendant's Exhibit, Nichols-Tanner Brake," and state from what car you took the dimensions, and the scale used in constructing the exhibit.

A. I took the dimensions from car "N" of the Connecticut River Railroad. The scale is one inch to one foot.

Cross-examination:

Cr.-int. 1. Please measure and state what is the extreme length of said car "N," according to this exhibit, from the outsides of the platforms.

A. Forty-eight feet and three inches.

Cr.-int. 2. What is the extreme length between windlass-shafts of the car represented in "Defendants' Exhibit, Springfield Brake, No. 1"?

A. Fifty-eight feet and nine inches, as nearly as I can measure. It may be a little fraction over or under it.

2071 Cr.-int. 3. What is the extreme length between windlass-shafts of the car represented in "Defendants' Exhibit, Springfield Brake, No. 2"?

A. Fifty feet and five inches. It might be a little over or under.

Cr.-int. 4. What is the extreme length between windlass-shafts of the car represented in "Defendants' Exhibit, Springfield Brake, No. 3"?

A. Fifty feet and six inches.

Cr.-int. 5. What is the extreme length between windlass-shafts of the car represented in "Defendant's Exhibit, Nichols-Tanner Brake"?

A. Forty-eight feet and about three inches.

Cr.-int. 6. In making the model of the "Hervey Waters Radius Diagram, sheet No. 2," how have you obtained the radius and curves?

A. I took the tracing and put it upon the board I was going to make the curve upon, and pricked the lines of the curve, as shown by the tracing, through upon the board, and then tacked a track on to the board to correspond with the curves so pricked through.

Cr.-int. 7. Please state now how you obtained the curves in the model of the tracing "Defendants' Exhibit, 27th Street Curves."

A. I tacked the tracing down on to a large platform; then took as a point to start with the point marked "radius = 50′" on that one of the curves nearest the lines representing the depot buildings, and putting one leg of the compasses on that point, made a sweep with the other leg. I then placed one leg of the compasses on the point marked in red at the other end of the same curve, and made a sweep with the other leg. Then, at the point where the circles made by these two sweeps intersected, I placed one leg of the compasses, and stretched the other leg to correspond with the line of the same curve, as shown on the tracing, so as to see that the sweep that this leg of the compasses would make would correspond with said curve, and when I saw that it did correspond I took the tracing off the platform, and, with the compasses and the same points to work from, reproduced the same curves
on the model. I then took a channelling tool or plough-iron and
2072 made channels in the model to represent depressed tracks, cor-
responding in curvature with the curves obtained as stated, and added at each end of the curved parts stright lengths of track, long enough for one of these exhibit models to stand on.

JOHN A. HEARN.

Depositions of Jerry Perrin, Alfred Berney, Theophilus Chase, and Samuel B. Cushing, taken at Providence, Rhode Island, April 16, 1878, before Francis A. Daniels, U. S. commissioner.

Deposition of Jerry Perrin.

Direct examination:

Int. 1. What is your name, age, residence, and occupation; by whom are you employed, and how long have you been so employed?

A. My name is Jerry Perrin; am twenty-five years old; occupation, car-builder and repairer of all kinds of cars, especially the running-gear. I am employed in the repair-shop of the Providence and Worcester Railroad Company. I have been there eight years. I live in the city of Providence.

Int. 2. Look at "Defendants' Exhibit, Nichols-Tanner Brake," and state whether you have applied said brake to cars of the Providence and Worcester Railroad. If so, how long ago?

A. I have; eight years ago.

Int. 3. To what extent was the Tanner brake applied to the cars of the Providence and Worcester road eight years ago?

A. I believe we had it on five. I altered those five cars myself, and put on the Hodge brake.

Int. 4. Have you of late applied the same brake to car 27 of said railroad, and in the manner represented in said "Exhibit Nichols-Tanner Brake"?

A. I have, sir.

2073 Int. 5. What is the length of the centre lever between outside centres?

A. Four feet.

Int. 6. What is the length of the truck-levers?

A. Thirty-six inches.

Int. 7. And the length of the long arm of said levers?

A. Thirty inches.

Int. 8. Also the short arm?

A. Six inches.

Int. 9. These are the proportions, are they, of all the truck-levers on the passenger-cars, whether the Tanner brake or the Hodge brake?

A. Yes, sir. It don't make any difference what brake we use; they are all the same length.

Int. 10. Please look at "Defendants' Exhibit Lever Scales," and state whether you have applied said exhibit to the brake, as represented in said "Exhibit Nichols-Tanner Brake." If so, how did you apply the said lever scales?

A. I have, sir. I cut holes through the floor of the car, just back of the ends of the centre lever, and between it and the top of the truck-lever, and attached the lever scales to the rods running from both ends of the centre lever to the truck-levers.

Int. 11. Look at "Defendants' Exhibit Turn Buckle," and state where you applied it, reference being had to the aforesaid exhibit.

A. I applied it in each rod running from the centre lever to the truck-levers, at a point between the truck-lever and the lever scales.

Int. 12. After putting on the mechanism in this way, did you make any adjustment? If so, what, and how did you do it?

A. I turned the turn-buckle until each one of the balances of the lever scales showed, when the car was standing still on the straight track, the same number of pounds pressure.

Int. 13. Look at "Defendants' Exhibit, Springfield Brake, No. 2," and state whether, on the following day, you applied to the same car a brake like the brake represented in said exhibit; and, if so, whether you applied the same lever scales to said brake.

2074 A. I did, sir; except that the brake like this exhibit was only put on from one end of the car.

Int. 14. State where and how you applied the lever-scales to said brake.

A. I first took the centre-lever of the Tanner brake off, then connected the two jaws right together that were on the Tanner brake at one end of the centre-lever, which left one of the lever-scales in the same place they had been in, in the Tanner experiment; thus having them in the long rod represented in said exhibit. Then I jacked up the car, ran one truck out, turned it end for end on the track and ran it under the car again, so as to bring the truck-lever which had previously been at the outside end of the truck, at the inside end. I then cut a hole through the floor of the car between the body-bolster over that same truck and the first cross-piece of the car floor, and inserted the lever-scales into the short rod shown in said exhibit between the bolster and the next floor-joist of the car body.

Int. 15. After you had got the mechanism on as you have already described, did you make an adjustment? If so, how?

A. I did, by turning the turn-buckle until both scales indicated the same power upon both trucks.

Int. 16. What was the diameter of the brake-wheel used in both experiments?

A. Sixteen inches.

Int. 17. And what the diameter of the shaft on which the chains wound?

A. One and a half inches, the levers in the trucks being the same.

Int. 18. From which end was the brake operated in both cases?

A. The brake was operated in both experiments from the end of the car nearest the engine.

Int. 19. Look at "Defendants' Exhibit, Hodge brake," and state whether you applied said lever-scales to a brake on the same car, constructed like said exhibit. If so, at what places in the rods did you apply said lever-scales?

A. I did. I inserted one of the lever-scales in each of the rods running from the floating cross-lever to the truck-lever.

2075 Int. 20. When you had the lever-scales attached to the Hodge brake, did you find that they balanced, without requiring any adjustment to make them balance, on the application of the brake?

A. I did, sir.

Int. 21. Did you then let out the brakes of one truck one inch by turning the nut on the brake-beam back one inch, thereby making the brakes on that truck very loose, the brakes on the other truck remaining unchanged, and then apply the brake? If so, what variation, if any, was there between the power on the two trucks?

A. I did, sir. When I applied the brake there was no variation in the power on the two trucks, as shown by the lever-scales.

Cross-examination by M'r Cozzens:

Cr-int. 1. Are you certain that the Tanner brake, as used eight years ago on the Providence and Worcester cars as you have stated, was in all respects arranged on those cars as in the "Defendants' Exhibit, Nichols-Tanner brake?"

A. Yes, sir; except that there were no interchanging holes in the centre-lever as they are in the model. I think there were turn-buckles in the rods running from the centre-lever to the truck-levers, as in the model, but I cannot swear to that. The cars were forty-three feet long.

JERRY PERRIN.

Deposition of Alfred Berney.

Direct examination:

Int. 1. What is your name, age, residence, and occupation?

A. Alfred Berney; age, forty-three; residence, Jersey City, New Jersey. I am a manufacturer and inventor.

Int. 2. Have you witnessed certain experiments for the purpose of testing the power of different brakes of late?

A. I have.

2076 Int. 3. Please name the brakes in the order in which the experiments took place.

A. The so-called Tanner brake, the Springfield brake, and the Hodge.

Int. 4. How were the scales by which the power conveyed to each brake was measured, applied to the different brakes?

A. They were put up through the floor of the car, as indicated by "Defendants' Exhibit, Lever Scales." I should think those (pointing to exhibit) were the ones.

Int. 5. To which brake was the first test applied, and under what circumstances, and on what track or tracks? Please explain fully.

A. The Tanner brake, on the 28th of March, 1873. We started out with an engine and one passenger-car with no seats, empty. We went up the road, and before we got to what is called the Ledge Curve this side of Valley Falls on the Providence and Worcester road, the brakeman set up the brakes at twenty-eight pounds, and in going round the curve it varied some ten pounds, the end that I was on, which was the north end of the car. There was a little tremor to the scale, varying from one to two pounds with the motion of the car. In going back from Valley Falls the brake made the same exhibit as before. On the straight track it balanced. I looked at both the scales when they were set up by the brakeman, and noted that they both indicated twenty-eight pounds. I only looked at my end when they were going round the curve. I didn't make any notes of what took place on the Eaton Curve.

Int. 6. After these experiments, and the car had returned to the shop, what further test was said Tanner brake put to?

A. The car was shoved in on what is called a very sharp curve in the yard near the paint-house. The brakes were set up by the brakeman; the scale at the north end indicated six pounds, and the one at the south end thirty pounds. The locomotive pulled the car back and forth with the brakes set up. It made a variation on that brake at the end that I was on of from ten to fifteen pounds in going round the curve.

Int. 7. Please state the next experiment in order.

2077 A. The next experiment was the next day, with the same engine and same car, and with what I was informed was the Springfield brake. One of "Defendants' Exhibit, Lever Scales," was set up in a different part of the car from where it was the day before, set further apart, so as to adapt the scales to the Springfield brake. We went up to this side of the Ledge Curve, and the brakes were set at twenty-four pounds on a straight track. Upon the curve the variation was from twenty-four to sixteen pounds on the end that I was on, the north end; that is, it went from twenty-four down to sixteen. As the car went off the curve it went back to twenty-four again. The car was then hauled back to the paint-shop, and was put to the same test as when the so-called Tanner brake was on. It was braked up, and six pounds at the north end and thirty pounds at the south end was the pressure indicated by the scales. When the brakeman had pulled the brake to six pounds, at the end I was on, I told him to stop, because I wanted to see what power was on the other end; I went over and found thirty pounds pressure at the south end, that is, the pointer on the scales indicated thirty. It was then hauled up and down on the curve the same as the Tanner brake and indicated the same variations.

Int. 8. What other experiments did you thereafter witness, and what were the results?

A. On April 23d, the same car and the same engine, with what I was told was the Hodge brake, was tested. An engine was attached to the car and it was run over the track to the Ledge Curve, and there the brake was set at twenty pounds pressure on a straight track, and there was no variation in drawing it round the curve. There was a little tremor of the scale, the same as on the straight track, but no variation. It was then hauled back to the paint-shop and put on the curve. The man braked up the brakes to sixteen pounds at one scale and twenty at the other. That is, there was sixteen pounds on one brake and twenty on the other.

Int. 9. Did you note whether the connections with the lever-balance in the Hodge brake were the same as in the Springfield and Tanner brakes?

A. I noticed that in the Hodge brake, the truck rod connec-
2078 tions and the floating-lever connections, the lever-scales were placed in the middle hole, while those in the Tanner and Springfield brakes were in the upper hole of "Exhibit, Lever Scales."

Int. 10. Did you observe whether there was any sliding of wheels in these or subsequent experiments; if so, state what you observed?

A. Not in these experiments, but subsequently I did. At the end of each experiment which I have testified to, or about the time, but not when we were going round the curve, we braked up on the wheels to slide them. The Tanner brake was set at forty-two pounds on a straight track. The scales indicated that at each truck. The outside wheels of each truck slid at this pressure. The Springfield brake was set up, and to the best of my recollection it took the whole power shown on the scale, forty-eight pounds, to make the wheels slide. The Hodge brake was set up at thirty-eight pounds pressure, and, to the best of my recollection, all the wheels slid. It was gradually let off to twenty-four, when they rolled. At twenty-six it held the wheels still. The brake-shoes were so hot in all the experiments for sliding the wheels, the Tanner, Springfield, and Hodge brakes, you couldn't bear your hand on them. All these experiments for sliding the wheels were made on a straight track. In the experiments for sliding the wheels the brake shoes were all hot because the Tanner brake-shoes were hot, and I said the other shoes must be hot so as to give them a fair test.

Cross-examined by M'r Cozzens:

Cr.-int. 1. When the wheels slid in the sliding of the wheels' experiment, were you where?

A. I was in the car. Sometimes I was in the car; sometimes I was standing on the track.

Cr.-int. 2. Where were you when the sliding took place, as you have just detailed it in the various experiments?

A. During some of the experiments I was in the car, and during some I was on the track.

Cr.-int. 3. During those times when you were in the car how could you tell whether the wheels were sliding or not?

2079 A. I would be at the scales. The brakeman would say they were sliding. I would note the pressure and immediately run out and see if they slid, myself.

Cr.-int. 4. Where did you run out to?

A. I went out on to the platform and leaned over the step.

Cr.-int. 5. Did you do this in all cases before the car stopped?

A. Yes, sir; in all cases, just as quick as I got the signal from the brakeman that they were sliding. Or, if I was on or near the track and saw them sliding, I would run and get on as quick as I could and look at the indicator.

Cr.-int. 6. Was the brakeman turning the wheel at the time he called out to you that the wheels were sliding?

A. He would brake up a little and then look over the side to see if the wheels slid.

Cr.-int. 7. Then after the brakeman called out to you that the wheels were sliding, the car was dragged some distance in all the experiments, was it not, with the wheels sliding?

A. Yes, sir.

Cr.-int. 8. If the car was dragged with the wheels sliding, it would very soon heat the brake-shoes, wouldn't it?

A. I don't appear here as an expert.

Cr.-int. 9. Cr.-int. 8 repeated.

A. I think it would not, sir; if it held the wheel perfectly still.

Cr.-int. 10. The brake-shoes wouldn't get hot when they were not touching the wheels, would they?

A. No, sir. It is in the act of the wheels when they run rapidly and the shoes trying to stop them. But after the wheel was stopped, being no friction, there would be no heat except the heat that had been already developed.

Cr.-int. 11. At the time these wheels were slid as you have stated, how fast was the car running?

A. I told the engineer to go about the passenger rate, twenty to twenty-five miles an hour.

Cr.-int. 12. You have stated that in the Tanner brake experiment at
the Ledge Curve, the brakeman set the brake at twenty-eight
2080 pounds, and in going round the curve it varied ten pounds at the
end you were at, nearest the engine. In which direction, with reference to the motion of the car, did the curve turn—to the right or to the left?

A. It turned round to the left.

Cr.-int. 13. Was this variation of ten pounds from the twenty-eight pounds down?

A. Yes, sir; down to eighteen.

Cr.-int. 14. Was there any variation from the twenty-eight pounds up?

A. No, sir.

Cr.-int. 15. Didn't go beyond twenty-eight pounds?

A. No, sir; steadily went down. When it got to the lowest notch, I noted that as eighteen pounds.

Cr.-int. 16. Did the index go steadily down from twenty-eight pounds down to eighteen, without tending back towards twenty-eight at all?

A. There would be a little tremble but no going back. It would keep steadily going down. Then as we went round the curve on to the straight track, it would go back again.

Cr.-int. 17. While this was taking place at the truck where you were, do you know what was taking place at the other truck?

A. Not of my own knowledge.

Cr.-int. 18. Do you know the radii of any of these curves?

A. No, sir.

Cr.-int. 19. In regard to the Springfield brake experiment did the variation which you have spoken of from twenty-four pounds down to sixteen, continue steadily down from the twenty-four to the sixteen?

A. It did, just the same.

Cr.-int. 20. Was there any variation above the twenty-four?

A. No, sir; if there had been I should have noted it.

Cr.-int. 21. And it tended steadily down without going back to the twenty-four until you got off the curve?

A. Yes, sir; as it went off the curve it let up.

ALFRED BERNEY.

2081 *Deposition of Theophilus Chase.*

Direct examination:

Int. 1. What is your name, age, residence, and occupation?

A. My name is Theophilus Chase; age, twenty-eight; residence, city of Providence. I am a carpenter; work principally on railroad cars in the repair-shop of the Providence and Worcester Railroad.

Int. 2. Have you ever acted as brakeman on the Providence and Worcester Railroad; if so, when, and how long?

A. Yes, sir; off and on all the time for the last two years. I have had charge of the yard there, braking cars, both passenger and freight, and working in the shop. All the braking that is needed I have to see to myself.

Int. 3. While certain experiments were carried on a few days since, on a car of the Providence and Worcester Railroad for the purpose of testing the power of different brakes on each truck, did you set up the brake until you exhausted the power on the lever-scales when said scales were applied to the Tanner or centre-lever brake?

A. I did.

Int. 4. You brought both scales up to forty-eight pounds?

A. Yes, sir.

Int. 5. Did you also, when the brake was applied to a car with the Springfield brake on, set up the brake until the scales indicated forty-eight pounds on both trucks?

A. Yes, sir.

Int. 6. Were there one or two chains winding around the brake-shaft?

A. On the Springfield brake there were two chains, on the Tanner there was one.

Int. 7. Did you also set up the brake on the car when the Hodge brake was applied, and note the power on the scales?

A. I set it up as far as the scales would go on both ends, so that the scales indicated forty-eight pounds.

2082 Cross-examination by M'r Cozzens:

Cr.-int. 1. Has your experience as brakeman enabled you to know, when you look at the brake, whether the adjustment of the shoes to the wheels is properly made?

A. On some parts of them I do, and some parts I don't pretend to have anything to do with or say anything about.

Cr.-int. 2. Do you know when a brake is in a proper state of adjustment?

A. I do.

Cr.-int. 3. Do you know when a brake is so adjusted that the shoes will all come up against the wheels simultaneously with as nearly equal power as the leverage given to the brake will permit?

A. Yes, sir.

Cr.-int. 4. How perfectly was the Springfield brake, as it was called, in these experiments adjusted at the time the experiments commenced?

A. I can't say anything about that.

Cr.-int. 5. Did you pay any attention to it to see?

A. No, sir; I only attended to the braking.

Cr.-int. 6. Did you, with each of the three brakes—the Tanner, the Springfield, and the Hodge—apply the brake with about the same force, as near as you could tell?

A. Yes; about the same force. There were some variations. One would set up a trifle harder than the other.

Cr.-int. 7. There wasn't much difference, was there?

A. There was some difference; not to amount to anything.

THEOPHILUS CHASE.

Samuel B. Cushing, of the city and county of Providence, in the State of Rhode Island, being duly sworn according to law, testifies and says as follows:

Deposition of Samuel B. Cushing.

Direct-examination:

Int. 1. What is your name, age, residence, and occupation?

2083 A. Samuel B. Cushing; reside in the city of Providence; am a civil engineer by profession; am sixty-two years old. I am employed by the Providence and Worcester Railroad as a civil engineer, and have been ever since the road was surveyed. I began the survey of the road, I think, in 1844; finished the preliminary survey that year, and the construction was commenced the next season. The road was finished in 1846, I think.

Int. 2. Do you know of a curve in the main line of the Providence and Worcester road, near Valley Falls, called the ledge curve?

A. Yes, sir; between Valley Falls and Central Falls.

Int. 3. According to your survey, what is the radius of said curve?

A. Fourteen hundred and thirty-two (1,432) feet, or a four degrees' curve.

Cross-examination by M'r Cozzens:

Cr.-int. 1. Going from Providence to Worcester, in which direction does that curve turn, to the right or to the left?

A. From Providence to Worcester, it curves to the left.

SAMUEL B. CUSHING.

Examination taken, reduced to writing, and by the witness subscribed and sworn to, before me this sixteenth day of April, A. D. 1873.

FRANCIS A. DANIELS,
U. S. Commissioner.

Deposition of Henry Waterman.

Reported by J. M. W. Yerrinton, at Boston, April 18 and 19, 1873.

Direct examination:

Int. 1. What is your name, age, residence, and occupation?

A. Henry Waterman; 55; Hudson, New York; mechanical engineer.

2084 Int. 2. Have you been examined on the part of the complainant in this case? If so, about what year?

A. I did not expect to be asked about that. I thought you were going to ask about the Springfield brake. I have been examined by the complainant in this case; I think it was in 1868.

Int. 3. How long have you been a mechanical engineer?

A. I was put into a machine shop in the year 1831, and have been from that time to this an engineer.

Int. 4. Please state whether you are familiar with all kinds of machinery, especially railroad machinery, and at how early a day did you become acquainted with railroad machinery, and what have been your advantages for obtaining a knowledge of it, and what inventions have you made in railroad machinery that have gone into use? Please explain on all the points inquired of, in detail.

A. In the year 1837, I was employed to take charge of the machinery of the Hudson and Berkshire railroad, and continued, directly or indirectly, connected with that road something like seven years. Then there was an interval of a few years that I was engaged at fire-engines; and in 1847 I commenced building locomotive-engines for the Hudson River Railroad, and continued my connection with the Hudson River Railroad until 1854. Since that time I have withdrawn from direct connection with railroads, and have been making experiments at novel contrivances, etc., connected with railroad machinery, and am so engaged to-day. In 1840, I constructed the first eight-wheel locomotive, I think, that ever ran successfully; that is, the connection of four driving-wheels with four truck-wheels. The model was adopted for engines built for the Western Railroad. Major Whistler examined it, and constructed some after it. I made the first swinging-bolster passenger-car in 1839, and ran three such cars on the Hudson and Berkshire railway. I was the inventor of the cast-iron saddle for locomotive cylinders on these locomotive-engines. I think I used the first India-rubber springs ever used on a railroad, as early as 1839. I invented and constructed the first dummy-engine ever
built for hauling cars in the streets of cities. I invented what is
2085 called the pop safety-valve, for relieving locomotive boilers, which
I did in 1853, of which about six thousand have been sold and gone into use. I have invented, and am now running, a novel slide-valve upon a locomotive-engine, by which I guarantee to the railroad (the Albany and Susquehanna Railroad or Delaware and Hudson Canal Co.) a gain of 20 per cent. in power over the best locomotive of its class. I was informed last week of its perfect success.

Int. 5. Have you of late witnessed the operation of the Springfield brake on a train of cars running between Boston and Albany? If so, when did you witness such operation, and state in detail what you noticed in reference to the operation of the same.

A. Yesterday I witnessed the operation of a train the cars of which, with one exception, were fitted with the Springfield brakes. There were four cars with the Springfield brake and one with the Hodge brake on the train. I saw the brake for the first time yesterday morning, at five o'clock, prepared to go out upon the Boston and Albany road. I was requested to see if the rear car, specially fitted with the Springfield brake, had power to hold what is called the slack of the train, and to note generally the power and action of the brake at the stations, and also running down the inclined planes or grades. I at once noticed a defect in a car that appeared to have just come out of the shop. There was a nut upon the shaft of the windlass that interfered with the natural action of one of the chains, and the first time it was wound up, I think at one of the first stations—the Ashland station, I think—the upper chain caught on the nut, and the car did not show its full power in stopping, and the train ran by the station. The car failed to draw upon the train and hold back what it should. After that it caught a few times, but generally ran free, in the normal condition, upon the barrel; and when it did run upon the barrel properly, free from this nut, I had a good opportunity to watch its actions and note carefully the result.

Int. 6. Now go on from station to station, and make such remarks as you think proper.

2086 A. With regard to holding the train at stations, I think Ashland station was the first one we ran by. I am quite sure it was. It ran by, I should judge, pretty near two-thirds the length of the train. We ran by another station; the name I don't recollect, only it was on one of the grades descending towards Springfield. Otherwise the stops were very good, fair stops. On running upon the inclined planes, the brake was applied.

Int. 7. Please state where these inclined planes were on the line of the road.

A. The first trial of that kind was made upon the inclined plane running down into Springfield from the east. The next great trial was running from the summit—I think the grade commences at Dalton station—down to Pittsfield; then, again, running down from Schodack to Albany.

Int. 8. State what you observed on these different grades as to the holding power of the brake.

A. On all of these grades the brake on the rear was used to hold the slack of the train, and to hold the train. On the grades that are said to be fifty or sixty feet to the mile—that is, the grade going down into Springfield, and the grade from Schodack to Albany—the brake on the rear car (being the Springfield brake) held four cars in the train. On the grade, said to be about eighty feet to the mile, from Dalton to Pittsfield, the brake held three cars. Some of these grades had curves. The Springfield grade is on a straight line; the grade down from Dalton is mixed, straight lines and curves; and also the grade from Schodack to Albany. The latter grade is generally tolerably straight. In regard to holding, I observed that the application of the windlass-wheel and the part of the shaft where the chain winds on the Springfield brake, was not sufficient to develop the power of the brake fairly, owing to the want of size of the wheel; that, in comparing it with the Hodge brake, using the same size windlass and shaft, the same force upon the wheel applied but one-half the force to the brake-blocks on the wheel, and that the brakemen had to use their hands harder and with more force to produce the requisite power.

Int. 9. Did you notice whether the Hodge brake had the same shaft and wheel that the other brakes had on which to wind the chain?

2087 A. It had the same. I can say, generally, that upon examining the brake and its action, yesterday, it was a brake that in practice would compare favorably with any of the brakes used before the invention of the Hodge brake.

Int. 10. You speak of the windlass-shaft on the rear car of the train, which had the Springfield brake on, having a nut on that obstructed the normal winding of the chain round the barrel. What effect did such nut have upon the application of power to the wheels? And was such defect due to the brake or the imperfection of the mechanism?

A. The effect was to wind up one chain much more rapidly than the other; indeed, so as to leave the other chain quite slack; to apply the brake only to one truck; and, by practically enlarging the barrel upon which the chain wound—by increasing its diameter—to destroy the force about one-half, I should think, of that single brake.

Int. 11. Were there nuts upon the shaft upon which the chain winds on the Springfield brake, on the other cars in the train?

A. I did not observe one on any other car in the train. This was the front end of the rear car. It was just the worst place they could possibly put it.

Int. 12. Was it proper that such a nut, for such a brake, should be upon the barrel on which the chain winds?

A. It ought to have been put through and riveted down smooth, like the other. It was a very improper place for a nut, and acted very badly in this trial. It ought to have been riveted down, and made a flush cylinder to wind the chain upon.

Int. 13. Was this nut merely incidental, or was it part of the brake?

A. I consider it a great oversight in the parties who put it on, and not necessarily a part of the brake.

Int. 14. Was it in consequence of this nut being improperly applied that the power was shut off from the wheels in a manner to prevent the brake from doing its proper duty?

A. I think the brake lost one-half of its power by the action of the
chain over that nut. After working the brake a few times, it did
2088 finally pass round the shaft without being obstructed by the nut.
It improved by practice, and at last ran very well. It caught
once or twice, but not so seriously after that, and generally it ran very well after that. I will here state that in the experiments when running down the grades west of Springfield, the brakeman, M'r Gardner, was placed upon the rear platform of the car, and did the braking from that position, in order to work the brake in a fair way, and I found the action very much improved. I will here state that on the high grades running down from Dalton, the speed of the train being under the control of M'r brakeman Taylor, of the western division, he placed himself so as to signal to M'r Gardner through the car, and did signal to him to take off the brake, as the train was going too slow.

Int. 15. Was the train, at this time, being entirely controlled on the grade by the action of the Springfield brake on the rear car, operated from the rear end?

A. It was. (M'r Cozzens. How do you know it was?) I will answer that. I charged the other brakemen not to use the brakes. I passed continually through the train to see how the brakes were holding, and to see that there was no other brake applied on the train.

Int. 16. Was there any nut on the barrel on which the chain winds to obstruct the winding of the chain at the rear end of the rear car?

A. No; I did not observe that. The train was running so satisfactorily that it did not occur to me to examine it.

Int. 17. Then, if I understand you, there were but two occasions, during the whole trip from Boston to Albany, in which the train ran past stations?

A. There were but two where the running by was observable, I mean to say.

Int. 18. Was this a way-train, making all the stops?

A. I believe they made all the stops. They made a great many stops. Not being familiar with their usual time schedule, I cannot answer as to the stops.

Int. 19. Who was the brakeman on the rear car?

A. M'r Gardner.

Int. 20. George Gardner, the gentleman present?

2089 A. George Gardner, the gentleman present, I will say.

Int. 21. Who was the brakeman on the other part of the train?

A. M'r O'Brien had charge of the brakes in front of the train.

Int. 22. The William O'Brien present?

A. Yes.

Int. 23. What other persons were connected with the train in this operation of the Springfield brake, as you have stated yesterday, from Boston to Albany?

A. There were two regular brakemen belonging to the train with us, both east and west of Springfield. I know the name of but one of them—M'r Taylor, of the western end.

Int. 24. Was M'r Sayles, the complainant in this case, present, to observe the operation of said brake from Boston to Albany?

A. M'r Sayles was present all day.

Int. 25. I think you have stated that there was one Hodge brake upon one of the cars of the train. Was that brake used to stop the train at any point between Boston and Springfield?

A. I do not know of its being used. I charged the brakemen not to use it, and saw no evidence that it was used. It was not used in my presence.

Int. 26. The whole reliance to stop the train was upon the four cars having the Springfield brake, if I understand you?

A. That was so.

Int. 27. Was there occasion to use the Hodge brake from Springfield to Albany? and, if so, when and by whom?

A. It was used in making the stops at all the stations on the high grades, and, indeed, all the stops, as far as I know.

Int. 28. Was it used in taking the train down the grades on the eastern slope of the Green Mountains; or was reliance placed entirely on the rear car, with the Springfield brake, as you have already stated?

A. No brake but the Springfield brake on the rear car was used, within my knowledge, on any of these grades, except at stations.

2090 Int. 29. Why did you allow it to be used at stations?

A. It is quite necessary, to make good stops at stations, to use all the brakes on all the cars in the train, and consequently we were compelled to use that.

Int. 30. What do you think would have been the result had you depended upon the Springfield brakes from Springfield to Albany, as you did from Boston to Springfield?

A. I question whether we could have made as good stops at the stations going down without the use of that brake, for the reason that that car would be exerting all its momentum and no brake on it. It is making the brakes on four cars do the work of stopping five cars.

Int. 31. But you did make the brakes on four cars do the work of stopping five from Boston to Springfield?

A. We did; the grades were not so high.

Int. 32. But you thought it prudent to use all the brakes on the train on the grades between Springfield and Albany?

A. That is so.

Int. 33. Had the car with the Hodge brake been taken out, do you think you would have had any difficulty in taking the four cars with the Springfield brakes on from Springfield to Albany, and stopping at the stations as a train ought to be stopped?

A. I think there would have been no difficulty.

Int. 34. Do you know of any matter or thing of benefit to either party in this suit that you have not testified to? If so, you will please state it here.

A. Nothing occurs to me now.

Cross-examined by M'r Cozzens:

Cr.-int. 1. Have you for some years past been engaged, either by yourself or in connection with other persons, in introducing and in selling to railroad companies the safety-valve for locomotives to which you referred in your direct testimony?

A. I have, sir.

Cr.-int. 2. Have you received from these sales, as your share of the proceeds, a considerable sum of money?

A. I have, but I think I have given them an equivalent.

2091 Cr.-int. 3. Are you at the present time engaged in introducing and making sales of the same valve to different railroad companies?

A. I am so engaged.

Cr.-int. 4. Please mention some of the railroad companies which have purchased of you, or as the result of efforts in which you have taken part, the right to use these valves.

A. I think we have sold some of the valves to nearly two hundred roads.

Cr.-int. 5. In what part of the country? What proportion in New England?

A. Most of the New England roads use them.

Cr.-int. 6. Is the Boston and Albany Railroad one of the roads to which you have sold the right?

A. On the section of the road between Boston and Worcester they are using these valves; on the section west of Pittsfield, between Pittsfield and Albany, they are using them.

Cr.-int. 7. Do you consider it an important matter to you personally that the sales of the right to use these safety-valves, or the valves themselves, to railroads, should be as large as possible?

A. I think it is more important to the railroads themselves than it is to us. We have entirely prevented the explosion of steam-boilers. (Question repeated.) It is of considerable importance to me to sell as large a number of these safety-valves as possible.

Cr.-int. 8. Are you the inventor and patentee of one of the patents on this valve, which is used in its manufacture?

A. I am; and the original one.

Cr.-int. 9. About how long have you been engaged in efforts to introduce this valve to railroads?

A. I commenced in 1853, but had very ill success at first. The introduction of coal as fuel made such a device quite necessary. (Question repeated.) Well, about five years.

Cr.-int. 10. How many of the cars in this train which you went upon yesterday were just out of the shop, if you know?

A. I thought it looked as though there were two, if not three, just out of the shop; one, sure, the rear car.

2092 Cr.-int. 11. Were these two or three, and one sure, those which had the Springfield brake on them?

A. Two with the Springfield brake, and one with the Hodge brake. I may be mistaken as to the appearance of the car having the Hodge brake. It had a new platform on, what is called the Miller platform. It may be that that gave it the new appearance.

Cr.-int. 12. What was the number of this car having the Hodge brake on?

A. The number of the car having the Hodge brake, I did not observe.

(M'r Whipple stated that it was 134.)

Cr.-int. 13. Did you notice, before the train started, how well the Springfield brake on the cars in this train was adjusted?

A. I had no opportunity to notice at all. The train was in the depot in the dark; it was quite early, and I only noticed it after it ran out. I did notice it at the first station we stopped at.

Cr.-int. 14. How perfectly was the Springfield brake adjusted on the cars which had it?

A. It was adjusted, I thought, too tightly to work well. I will say, in explanation of that, the very tightness of the chain brought the chain round the barrel in contact with the nut; when it got a little looser by running, it wound up below the nut. I refer to car 123, in the rear of the train.

Cr.-int. 15. As you noticed these Springfield brakes, at the time the train had reached this first station of which you speak, did the slack of the chain seem to be all fully taken up?

A. The chains had not, I thought, sufficient slack. Indeed, it required but about half a turn of the wheel and shaft to tighten the brakes, and that brought the nut on the opposite side, in that half turn, directly in the wrong spot to pull well upon the chain.

Cr.-int. 16. Does or not this fact show that, for some reason, care had been taken to make the chains on the Springfield brake quite tight?

2093 A. I have no doubt the man who adjusted them tried to make them work with as little slack on the chain as possible, and thereby made a mistake. A little more slack would have worked better. Indeed, it worked better after the chains obtained a little slackness in use.

Cr.-int. 17. About how long did it take, after the train started, for these chains to acquire more slackness by use?

A. It seemed to improve at once in use—to slacken up.

Cr.-int. 18. Did there seem to come at once, or almost at once, a perceptible slackness of the chains in use, or such slackness as made, as you think, a perceptible difference in the operation of the brake in use?

A. I think it was a gradual sliding scale of slackness that it ran up to by use, until all the parts were brought up to a fair bearing.

Cr.-int. 19. Why, then, did you say that it seemed to improve at once, if it was gradual?

A. I don't think I used the best word there. I meant from that time, I did not mean with any sudden jump into slackness.

Cr.-int. 20. Then about how soon did the chain seem to become slack enough to produce this improvement which you speak of?

A. Well, I think as we approached what they call Charlton grade, which is about sixty miles from Boston. After that, I found no fault with it. We had been gradually working up to that point of efficiency. I speak particularly of car 123. (Question repeated.) The question is a hard question. Of course, the last clause of the previous answer meets that. I will say, it is not possible to fix the exact point when this brake was most efficient. It was a gradual sliding up to efficiency. It is not in my power to tell exactly when or where it was most efficient, or even truly efficient. I found no fault with if at the western end of this eastern division. It worked very efficiently.

Cr.-int. 21. So far as you could judge, did what you call the improvement in the operation of the Springfield brake begin soon after leaving Boston?

A. It did, at the first application of the brake, and it improved with every application of it.

2094 Cr. int. 22. In running the train over the distance thus spoken of, did the chains of the Springfield brake seem to gradually become more slack?

A. They did.

Cr.-int. 23. Should you think, from the way in which these chains were adjusted, before the train had reached the first station spoken of, that the man who adjusted the Springfield brakes had tried to adjust them as perfectly as in his opinion he could?

A. I have not the least doubt of it.

Cr.-int. 24. You have spoken of this nut on car 123. Was this nut on the back end of the eye-bolt?

A. Yes; where it passed through the windlass shaft, to hold the eyebolt in.

Cr.-int. 25. About how thick was that nut?

A. I should think it was half an inch. It looked like a very clumsy, large nut.

Cr.-int. 26. About how much, in parts of an inch, would the distance from the outside of the shaft, on the side where the nut was placed, be to the outside of the nut?

A. Well, considering the roundness of the shaft, I should think nearly three-quarters of an inch at the outside, owing to the squareness and roundness of the shaft being increased at the angles. I will say, in explanation of that, that I observed every time the chain caught, especially at the Ashland stop, there was a peculiar kink or link of the chain that carried it out to a much greater diameter than was due to the thickness of the nut; and it appeared to me that the real fulcrum was nearly two and a half or three inches from the centre of the shaft on which the chain was winding, by the peculiar location of the link of the chain on the nut.

Cr.-int. 27. Then the nut itself produced an obstruction of about three-quarters of an inch, did it?

A. I should think so.

Cr.-int. 28. How much did the outside of the eye-bolt project from the outside surface of the shaft?

A. I should think about an inch and an eighth.

Cr.-int. 29. Did you notice when the Springfield brake was applied on any of the cars, that the chains would kink around the eye-bolt in being wound up?

2095 A. I did not notice at all any kinking except on the front of this car, 123. The brake upon the baggage-car I noticed several times, and the chain wound very beautifully and evenly around the barrels, on all these occasions. I saw no kinking anywhere on the Springfield brake, except at this front end of car 123, in the rear of the train, over this nut.

Cr.-int. 30. Did you see M'r Sayles, who you say was present, wind up the brake several times on the front end of this rear car?

A. I did.

Cr.-int. 31. When he so wound it up, did you not notice that the chain kinked more or less around the eye-bolt?

A. I did notice M'r Sayles winding up and loosening it several times, in immediate succession, and sometimes it would catch around the eyebolt and sometimes it would not. Indeed, I got the impression that it was improving while M'r Sayles was working at it. I think his working it assisted in loosening it.

Cr.-int. 32. When the chain caught around the eye-bolt, how much did that shorten it; that is, how much did it quicken its winding, or how much would it take it up?

A. I can only answer it approximately. I think it shortened the chain an inch and a half. But that was not the worst difficulty—shortening the chain; it was practically increasing the size of the barrel on which the chain wound, and lessening the power exerted upon the brake. At one time, I noticed, when the chain was so caught, that practically the barrel was increased up to nearly three inches from the centre of the shaft; that is, the radius; one-half the diameter; at least two inches and a half.

Cr.-int. 33. In your judgment, what would be the comparative effect as to the power applied by the Springfield brake upon the two trucks of the car, when such a kinking of the chains as this takes place?

A. It would exert almost the entire power upon one truck of the car, and reduce that to about one-half its efficiency.

Cr.-int. 34. Did you observe whether there was a similar nut on the back end of the eye-bolt on the Hodge brake, which you say was in this train?

2096 A. I think there was. But the chain was slack, and it ran round the barrel directly below the nut. I am quite sure there was.

Cr.-int. 35. Suppose the chain had been so tight that it would have wound around the nut instead of winding below the nut, would there have been any difference in the effect of the Hodge brake upon the two trucks?

A. Not the least. The force applied would have been less, in consequence of this practical enlargement of the barrel, but it would have been equal on both trucks.

Cr.-int. 36. Did you notice whether or not car No. 78, the smoking-car with the Springfield brake on in this train, had also a nut on the back end of the eye-bolt?

A. I did not notice that car.

Cr.-int. 37. Did you notice whether the brake-shoes on those cars having the Springfield brake, fitted the wheels nicely and equally?

A. I thought they fitted the wheels nicely; but I thought the connecting-rod on the back brake of car 123 was the tightest, for the reason that it heated the shoes more running on down grades than the front ones.

Cr.-int. 38. You have stated in your direct examination that you observed that the application of the windlass-wheel and shaft on these Springfield brake cars was not sufficient to fairly develop the power of the brake. Please state what was the diameter of the windlass-wheels and of the portions of the shaft where the chains wound in those brakes?

A. I did not measure the wheel, but it looked to be about 16 inches, and the shaft at the bottom appeared to be an inch and a half.

Cr.-int. 39. These are the sizes commonly in use, are they not?

A. They are the sizes commonly in use.

Cr.-int. 40. During the portions of the time that you were employed upon the Hudson Railroad as you have stated, were you the master mechanic of that road?

A. I was.

Cr.-int. 41. What was the first form of double-acting brake which was used on the Hudson River Railroad while you were connected with it, if you know?

2097 A. It was the Tanner brake.

Cr.-int. 42. Are you familiar with the construction and operation of the Tanner brake?

A. I think I am.

Cr.-int. 43. Can you state upon about how many cars on the Hudson River road the Tanner brake was placed, during any portion of the time that you were master mechanic there?

A. The first that I recollect was a purchase of 500 freight-cars. If I mistake not, they all came to the road with it on. That is my best recollection. Whether or not it was applied to the passenger-cars just at that time, I cannot answer.

Cr.-int. 44. How was it afterwards?

A. Afterwards, they made experiments. Stevens called our attention first to the double brake, and I believe some of the cars had the Hodge on, but I am not sure.

Cr.-int. 45. Do you recollect whether these experiments of which you speak were under the charge of Major W. T. Ragland?

A. These experiments were under the charge of Mr. W. T. Ragland.

Cr.-int. 46. Were you called as a witness on behalf of the railroad company in a suit tried several years ago at Canandaigua, brought upon the Hodge brake patent against the New York Central Railroad?

A. I was.

Cr.-int. 47. Do you recollect being called upon to testify in that suit in reference to the effect upon the Tanner brake of the passage of a car with the brake applied on a straight track around a curve?

A. I do recollect.

Cr.-int. 48. Did you state in that testimony at that time, that if the tops of the truck-levers were so arranged that the line of draft from the centre-lever to the tops of the truck-levers would be as nearly as possible in a line with the king-bolts of the car, there would be no material difference in the effect produced upon curves by the Tanner brake, when a car with the brake applied passed from a straight track on to a curve?

2098 A. I did say so, and still say so.

Cr.-int. 49. There is no question in your mind, is there, about the correctness of this?

A. Not the least.

Cr.-int. 50. Was there considerable testimony given upon this point at said Hodge trial?

A. There was quite an effort to injure the character of the Tanner patent in that particular.

Cr.-int. 51. Did you make any mathematical calculations in reference to this point at that trial?

A. I did.

Cr.-int. 52. Will you please state, so that it can readily be understood, what the nature of that calculation was, and what the result of it was?

A. I made a calculation by figures of the lengthening and shortening of the rod due to a radius of 800 feet, I think, on the Tanner brake, and I found the greatest variation only $\frac{2}{1000}$ of an inch in length. I also made an experiment before the jury there with the radius bars, showing how infinitesimal the variation was in the Tanner brake, going around curves.

Cr.-int. 53. And did you at this trial testify in court to this slight difference, being only about $\frac{2}{1000}$ of an inch?

A. I did.

Cr.-int. 54. Please state whether or not this calculation of yours was based upon the assumption that the tops of the truck-levers in the Tanner brake were arranged so that the draft from the centre-lever to them should be as nearly as possible in line with the king-bolts of the car?

A. It was.

Cr.-int. 55. I understand you, that in your railroad experience since that time, you have seen no reason to change this view?

A. Not in the least.

Cr.-int. 56. You say you made a mathematical calculation at this trial; will you please state whether you have paid particular attention to mathematical subjects, and whether you have, in the course of your practical life, been frequently called upon for various purposes to make accurate and important mathematical computations?

2099 A. When I was quite young I was known to show a special aptitude for mathematics. I went through all the branches of mathematics before I was fourteen years of age, without any effort; and have since been called to make very complicated calculations, and never found any difficulty in making any calculation I desired.

Cr.-int. 57. Have you also been very familiar, practically, with important and complicated dynametrical experiments?

A. I have. I have made very perfect dynametric instruments, and have used them on railways in testing and measuring forces, very generally.

Cr.-int. 58. Have you also frequently been called on at various State fairs to superintend and conduct dynametric experiments, where nice results were required?

A. I have. I have made over 600 dynametric experiments with agricultural implements.

Cr.-int. 59. You have stated that at this Hodge trial at Canandaigua there was quite an effort made to injure the Tanner patent, in reference to the effect of the Tanner brake upon curves, as compared with its effect upon a straight track. Did that attack proceed from the plaintiff in that case?

A. It did; from the Hodge patent.

Cr.-int. 60. Was not the defence against that attack made, and the testimony you gave at the trial introduced, by the railroad company, the defendants in that case?

A. It was.

Cr.-int. 61. Have you or not, in your extensive railroad experience, become more or less familiar with the different kinds of double-acting brakes which from time to time have been used upon the railroads of the United States?

A. I have been perfectly familiar with all of them.

Cr.-int. 62. What is your recollection as to what was the first form of double-acting brake that was put into use by railroad companies?

A. My recollection is, that the first I ever saw was the Tanner.

Cr.-int. 63. Is it also your recollection that the Tanner brake continued in use by railroads generally until they adopted the Hodge brake or the Stevens brake?

2100 A. All that used a double brake continued the use of the Tanner brake until Hodge introduced his. The next step was to the Stevens brake.

Cr.-int. 64. Will you please state what has been your observation in respect to the use of double-acting brakes upon Southern railroads?

A. I do not know that I have any experience or observation of the Southern roads. None occurs to me now. My recollection is only a general recollection, and I cannot speak specifically at all.

Cr.-int. 65. Will you please state when you first heard of the Springfield brake?

A. I heard the name a great while ago, in these early cases, but never knew how it was made until last winter.

Cr.-int. 66. From whom did you learn how it was made last winter?

A. M'r S. M. Whipple told me how it was made. I had used that principle upon tenders, a long while ago, applied to one end of the car, and recognized his description, and judged of its action immediately upon that.

Cr.-int. 67. When did you first know or hear of the Springfield brake being used upon passenger-cars?

A. When I first heard of it, it was used at Springfield—a double brake—but I never knew its form or construction. I don't know whether it was used on passenger-cars or not. (Question repeated.) I first heard of its use on passenger-cars last winter.

Cr.-int. 68. You say you never saw it used until yesterday?

A. I never saw it used until yesterday. Understand, I have seen that same principle applied to tenders.

Cr.-int. 69. Please state whether or not it is important, in your judgment, in the running of passenger-trains, to apply the brakes to all the wheels of the train in making stops.

A. I do consider it of great importance.

Cr.-int. 70. Do you or not apply this answer to all the stops which a train has to make?

A. Well, I will say to all stops, but more especially to the sudden stops that are required to be made in rapid running. Its importance increases with the speed and the suddenness of the stop. 2101

Cr.-int. 71. Are you familiar with what are known as the air brakes, recently introduced upon railroads?

A. I think I am sufficiently familiar with them. I think I understand their action. One I have seen work, and the other has been described to me, so that I think I understand it.

Cr.-int. 72. Is there in any of these air brakes any other advantage over the hand brakes, than that the air brakes are, in the first place, under the control of a single mind, and that they apply the brakes to all the wheels of the train as nearly simultaneously as possible?

A. I do not know that there is any other advantage. True, the brakes work without brakemen, but yet the same number of men would be required as the gang of a train. I don't think it lessens the number. That is my present opinion.

Cr.-int. 73. Is the mechanism, and the application of it to cars and engine, more costly, and the expense of keeping in good repair greater with the air brakes than with the hand brakes?

A. It is, and for the reason that all the cost, expense, etc., of the hand brakes still continues, and this is in addition to it. I want to correct my answer in regard to those stops yesterday that I spoke of. I stated that the first stop was at Ashland. It was the first stop my attention was called to. What they call the Know-Nothing stop, at the Providence crossing, and the stops at Framingham, I paid no attention to. I had hardly got located on the train.

Redirect:

Int. 35. In your cross-examination, you have spoken of the Tanner brake, and stated that, under certain conditions, the power of the brake on the two trucks is comparatively equal, whether the car is running on a straight track or on a curve. How do such conditions, applied to the Springfield brake, affect its operation under the same circumstances?

2102 (Objected to because the witness did not say that it was "comparatively equal," but said there was no material difference in the Tanner brake between the power applied to one brake and the power applied to the other.)

(Question repeated in the light of the objection just made.)

A. Under the same conditions, the action of the Springfield brake is precisely the same as the Tanner. The conditions were, that the draft-rod from the centre-lever to the top of the truck-lever passed on a line with the king-bolt of the truck. Now, if the draft-rod in the Springfield brake passes from the windlass to the top of the truck-lever on a line with the king-bolt of the truck, the same rule will obtain, and the action will be the same in both cases. That is, the tension of the draft-rod and the action upon the brakes will not be seriously affected by the swivelling of the truck on passing from the straight line to a curve, or vice versa.

(Referring to "Defendants' Exhibit, Springfield Brake No. 2," the witness proceeded as follows:)

I now hold in my hand a model representing "Springfield Brake No. 2," in which the draft-rod from the windlass to the top of the truck-lever passes in a line nearly parallel with the sides of the car. In its present position the tension of the draft-rod will be affected by the swivelling of the truck measurably in proportion to the distance of the draft-rod from the king-bolt, at the point where it passes the bolster. Now, if I turn the top of the truck-lever over until the tension-rod practically passes through the line of the king-bolt, it is not practically affected at all by the swivelling of the truck. So with the action that takes place with the lever at the other end of the car. By turning the top of the lever over, to bring the draft-rod on a line with the king-bolt, it prevents the swivelling of the truck from affecting the tension of the draft-rod; and by the same law that I before stated in regard to the swivelling of the Tanner brake, the points of which were drawn out at Canandaigua.

Int. 36. By whom drawn out?

A. By M'r Hodge's expert.

Int. 37. Who, on that occasion, was M'r Hodge's expert?

A. M'r Hervey Waters, of Boston. I will here state that I consider M'r Hervey Waters one of the most accomplished of experts.

2103 Int. 38. What did he draw out on that occasion?

A. He overlooked the feature that I have now explained until it was presented to him, and I believe he then abandoned the idea at once, as a man of his sense would, and adopted my theory as correct. I will here state that I am not surprised that M'r Waters did overlook it, for M'r Tanner himself had overlooked it in all the practical applications of his brakes that I knew of up to that time; for, in all the brakes that I had seen M'r Tanner apply, he entirely disregarded the law I have just spoken of, and placed the draft-rods so that they would be affected practically by turning curves.

Int. 39. Are the conditions you have named observed in the every-day application and operation of brakes? If not, why not?

A. They are not observed at all; they are disregarded. The importance of it has been entirely ignored by the practical men who have charge of brakes. That is to say, they have never observed the want of it; and have never been careful to apply it in the best manner. I will state further that all the brakes I know anything of as they are practically used, are affected in some degree by the peculiar action that that takes place on curves.

For instance, I will commence with the Stevens brake and the Hodge. Whenever the draft-rod passes from the windlass to the top of the truck-lever, in either case, on a line parallel with the sides of the car, as is often the case, and the cars pass on to a curve, when the wheels of both trucks on the car are on the same curve, a perfect compensation takes place, so that the force upon the brakes is not affected by the curve; but in passing through a switch, where the different trucks are on curves reversed in their character, where one truck swivels to the right and the other to the left, the tension upon the draft-rod is increased or lessened, depending upon the exact position of the curve; and this action is general upon all the brakes; they are either tightened or loosened; and, as I have said that the same tension takes place in both the Tanner and the Springfield brakes, it includes all classes of brakes that I have to treat. I will say, that the difficulty in either the Hodge or the Stevens is not a practical difficulty in the least degree, I think. It exists
2104 in too small a degree to create any practical difficulty. I place the Hodge and Stevens in a class as self-adjusting brakes, and the Springfield and the Tanner as non-self-adjusting. By "non-self-adjusting," I do not mean to include the self-adjusting that is obtained by wear. In the early application of the Tanner brake and the Springfield brake, as I used it upon tenders, we used wooden shoes, and we generally considered that the unequal tension of the draft-rods would wear themselves into a good practical adjustment very soon through the wearing of the brake-shoes.

Int. 40. Please look at the drawings of a certified copy of the Thompson and Bachelder, or Tanner-brake patent, and compare the brake there represented with said brake as applied on "Defendants' Exhibit, Nichols-Tanner brake," and state whether it is practically the same brake?

A. Practically, it is the same brake. They are both of them imperfect in regard to swivelling. The draft-rod above spoken of does not pass in a line with the king-bolt of the car.

Int. 41. Which application is the more practical, the one seen in the drawings of the patent, or that seen in the "Exhibit, Nichols-Tanner brake"?

A. In what view "practical," M'r Whipple? Do you mean the most practical, or the best?

Int. 42. The best for every-day use as a car-brake, that represented in the drawings of the patent, or that represented in the exhibit?

A. M'r Whipple, I do not understand you really. You will have to explain.

Int. 43. Did you ever see the Tanner brake applied as represented in the patent? That is to say, the levers perpendicular to the centre of the car?

A. I never did, in practice.

Int. 44. Did you ever see in practice a Tanner brake where the truck-levers were connected with the centre-lever, as indicated in the drawings of the patent, as far in towards the centre-pin of the centre-lever as indicated in the drawings?

A. If my memory serves me right, I saw on the Camden and
2105 Amboy R. R. the Tanner lever and rods connected as shown in the drawing, in order to apply the McLaughlin bumping-brake. That is the only case that I now recollect.

Int. 45. In the case referred to, was the connection as far from the end of the lever as indicated in the drawing?

A. I think not as far.

Int. 46. How many inches should you judge from the end of the lever, assuming that the lever was four feet long?

A. I cannot state; I have no distinct recollection of the distance.

Int. 47. In view of the foregoing explanation, you will now please state in which the brake is more practically represented, in the exhibit, or in the drawings.

A. You must give the whole scope of the word "practically," in order to have me understand what you mean.

Int. 48. In other words, were you to apply the Tanner brake, would you apply it as in the drawings of the patent, or as in the exhibit before you, and already referred to?

A. I think I should apply it as in the exhibit. That is the way all the Tanner brakes have been applied that I have ever seen.

Int. 49. You will please look at the drawings of the Thompson and Bachelder patent, and make such remarks as you think proper in further illustration of the subject-matter in hand.

A. With regard to the line of the draft-rod in its passage from the centre-lever to the top of the truck-lever, it does not pass on a line with the king-bolt, but passes over to the opposite side, and where the line meets the bolster is some little distance from the king-bolt; and it is just in that degree affected by the swivelling of the truck. Consequently, the drawing is not perfect in that particular.

Int. 50. Assume that "Defendants' Exhibit, Lever Scales," are put into the truck-lever rods of either the Springfield or Tanner brakes, the proportions of the scale-levers being one to eighteen; that is, two inches in the short arm, and thirty-four inches in the long arm, and that the power between the tops of the long arms of the scale-levers is twenty-four pounds, what will be the power upon the long arms of the truck-
levers, and what the power upon the brakes of each truck,
2106 the proportions of the truck-levers being as five to one, or six
inches in the short arm to thirty inches in the long arm?

A. Where the force upon the scales is twenty-four pounds, as stated in the question, the tension upon the draft-rod of the truck-lever will be 432 pounds; the tension upon the connecting-rod from the fulcrum of the lever to the brake-beam will be 2,592 pounds, and the tension on the connecting-rod from the lower end of the lever to the opposite brake-beam will be 2,160 pounds. The force will be the same in all trucks of all brakes, under the same conditions of leverage.

Int. 51. Assume that the truck-levers of the Hodge brake are as above stated, and that the short arms of the scale-levers are one and one-quarter inches, and the long arms thirty-four and three-quarters inches, what power will twenty pounds on the tops of the scale-levers carry to the long arms of the truck-levers, and what to the brake-beams of each truck?

A. Under the conditions above stated, the force exercised upon the draft-rod of the truck-lever, which before was 432 pounds, is now 576 pounds; and the force upon the connecting-rod from the fulcrum of the truck-lever to the brake-beam, that was 2,592 pounds, will become 3,456 pounds; and the force upon the connecting-rod from the end of the truck-lever to the opposite brake-beam, that was 2,160 pounds before, becomes 2,880 pounds.

Int. 52. Look at "Defendants' Exhibit, Hodge brake," and state what office the worm performs on the windlass-shaft, and what the stop just back of said shaft?

A. The office of the worm is to take up the chain, and, it being made in the spiral or fusee form, to take it up rapidly at first, and slowly and very powerfully at last, when power is required. The stop is to save as much as possible the slack of the chain when the opposite windlass is at work, and also to hold the rod when the chain-connections are broken off, and allow the brake to be worked from the opposite end of the car.

Int. 53. Then, if I understand the matter, the Hodge brake at one end does not have to take the slack of the chain at the other end, when the stop before referred to is used?

A. It does not.

2107 Int. 54. What are your views of the comparative relation of the two trucks of a passenger-car to each other when the car is running under the application of the brakes to the wheels of the two trucks through the agency of the Tanner or centre lever brake?

A. The peculiar construction of the swivelling-bolster requires a certain degree of looseness, and from the fact that the longitudinal forces are above the point of bearing of the bolster in the truck, I have observed that upon the application to trucks generally there is a tendency of the trucks to fall back as the brakes are applied. My observation has been of the trucks on the Hudson River road, and I observe that they fall back, I should think, an inch in practice, judging by my eye only; I have never measured the distance; so that the force due to the application of the brake upon the truck, and the momentum of the car body, would have the effect to draw one truck, that is, the forward truck, nearer to the fulcrum of the centre lever, and the other truck, or back truck, further away from it, so as to materially affect the equal tension upon the two draft-rods; or, in other words, the back truck would experience more tension upon the draft-rod, and more force upon the brake-beams than the front one. There is a force, however, measurably tending to prevent that. That is, the tension upon the draft-rods themselves, which tends to draw the trucks together, or towards the centre of the car. I have never measured this, but in my estimate of forces the tension upon the draft-rod is not sufficient to overcome the power due to the action of the brakes.

Int. 55. What two forces are there to be overcome in a moving train before the wheels can be slid upon the track?

A. First, the rotation of the wheels, and the adhesion between the wheels and rail.

Int. 56. Will you please, under this head, illustrate the law of friction connected with the stopping of railroad trains, and state whether the power or force applied to the wheels by the brakes is just as effectual towards stopping the train at a high velocity as at a low velocity, and also whether the retarding force is according to the pressure, or according to the surface pressed upon?

2108 A. I was early taught that velocity or surface did not materially affect the question of friction, and all my experience and my dynametric experiments have confirmed that view; that is, that friction is not materially increased by increase of surface, or by velocity.

Int. 57. Does the sliding of wheels ever take place at a high velocity? If not, why not?

A. I have never seen it take place at high velocities. It is not apt to take place at high velocities, until a good degree of the power of rotation is consumed. When a force sufficient is applied, sliding will commence. That is, it is most apt to occur at slower speeds. That is, with reference to the running of railway trains.

Int. 58. Does a brake hold just as well with the same power when a train is running at a speed of thirty miles an hour, as when it is running at one mile an hour, or nearly at rest?

A. By the law I have just mentioned, the holding is not materially affected by the velocity.

Int. 59. Will or not a train be as thoroughly controlled when the aggregate force is unequally distributed on the wheels, as when equally distributed, provided that none of the wheels are slid?

A. It will be as thoroughly controlled.

Int. 60. What, if any, advantage is there, then, in having a truck that will, as far as possible, equalize the power on all the wheels of a car?

A. The advantage is in having the highest degree of efficiency or pressure upon the wheels, a holding power, without sliding any of the wheels.

Int. 61. Does the Stevens brake have these properties practically?

A. It has these properties theoretically.

Int. 62. But not practically?

A. Practically, there is a difficulty in so adjusting the Stevens brake without setting the brake-shoes too tightly to the wheels, from the fact that all the lost motion, or slack of connections, has to be provided for by the vibration of the end-levers, and these end-levers are 2100 frequently pulled out of proper vertical position by the action of the windlass rod upon the top of the lever; and practically they have to be adjusted so tightly that very often there is an undue friction of the brake-shoes upon the wheels to make the Stevens brake work efficiently. They used to complain of that feature upon the Hudson River road, and desired me, at one time, to make dynametric experiments to show that the friction was very great upon the Stevens brake-shoes. By their tightness, sometimes, the end-levers are pulled out of vertical position nearly on a straight line with the windlass-rod, which has a tendency to take off a large portion of the power from the wheels affected by that lever.

Int. 63. You have stated that you requested M'r Gardner to operate the Springfield brake on car 123 from the rear end. Please state what your object was in so doing.

A. I had in view developing all the features of the Springfield brake. The Springfield brake has peculiarities not possessed by any other brake, in this way: whenever the train is in motion, and the brake is applied to arrest the motion, the momentum of the body of the car above pressing forward, and the adhesion of the wheels below on the rail holding backward, by reason of the force of the momentum of the car body being applied to the truck at a point something like two feet and a half above the rail, the weight upon the forward wheels of the truck is increased, and a portion of the weight upon the back wheels of the truck is transferred to the front wheels of the truck. (When I speak of the weight, I mean the entire weight of the car, exclusive of axle and wheel.) Now, in the Springfield brake, the connecting-rods attached to the fulcrum of the truck-levers drew and acted upon the brakes of the front wheels of each truck, while the connecting-rods on the end of the levers drew and acted upon the hind wheels of each truck. By the superior force due to the power developed at the fulcrum of the lever, the brakes of the forward wheels of each truck would have an increased force, approximately equalling the increased weight upon the wheels, and the brakes upon the hind wheels of each truck would have a diminished force, approximately equal to the diminished weight upon them, and a greater 2110 aggregate force could be applied to the four wheels without slipping the wheels. This force and action do not in the aggregate increase the power of stopping the car by the tension of the brakes at the rear end, because the aggregate power would be the same in both cases, and the action the same in both cases; that is, the same whether the brake was applied from the rear end of the car or from the forward end of the car, as far as the development of power was concerned, if none of the wheels in either case slipped. But applying the brake at the end of the car would, in the experiment, have given full efficiency to the Springfield brake, in case it had produced any slipping of the wheels. In view of what I have stated, I consider that when the rods are evenly adjusted with the Springfield brake (by that I mean, adjusted so as to draw uniformly upon both trucks), when the weight at the rear of the car is applied, a greater power of holding the train without slipping the wheels is attained, than with any brake I have ever seen or heard of. I have been led into these reflections and convictions by observing that on cars where the Stevens brake was applied in the rear to each truck, the wheels were most likely to slip upon the application of the brakes when the force applied to each wheel was approximately equal; or, in other words, the wheel which had the least weight upon it would be the first to slip.

Int. 64. William T. Ragland, otherwise known as Major Ragland, has testified in behalf of the complainant in this case, to wit, July 27, 1871, in relation to certain tests performed by him on the Hudson River road, about the year 1852. Have you any knowledge of such tests being made on the cars of that road? If so, what do you know about them?

A. I have knowledge of the tests spoken of. When I took a position on that road under M'r Starks, I was placed in nominal charge of the entire mechanism of the road, the rolling-stock. However, under that, I never interfered with either department, except the locomotive. I continued in that nominal charge until M'r French took charge of the
road in 1853. I think during the summer of 1852 M'r Stevens,
2111 the patentee of the Stevens brake, brought there his models and
plans, and we all approved of the plans, and they were applied at
once, in an experimental way, to a car in M'r Ragland's department, and the trials proceeded. There were several objects to be attained by the Stevens brake. It was to attain greater efficiency in making sudden stops; also, to save the wearing of wheels; and I watched the experiments with considerable interest. The trials resulted favorably, and the Stevens brake was approved, the patent purchased by the company, and the brake applied to the cars.

Int. 65. Do I understand that these tests were made as between the single brake and the Stevens, or between it and the Tanner brake?

A. I have no recollection of ever seeing the Tanner brake on a passenger-car on the Hudson River road.

Int. 66. M'r Ragland has stated that as the result of those experiments he came to the conclusion that the Tanner brake would wear out only one set of wheels where the single brake would wear out three sets of wheels. Is that true in relation to the Stevens or any other brake?

A. It cannot be possibly true with reference to that trial, for the reason that the trials were only, as M'r Ragland says, for four months, and the warranted life of the wheel, the builders' warrant, was for twelve months under any condition, whether single or double brakes were used.

Int. 67. Then there was no comparison, at these tests, as between the single brake and the Tanner brake?

A. I know of no such comparison. I do not think that any such comparison was made.

Int. 68. How does the weight of cars, as used thirty years ago, compare with the weight of those used at the present day; and also, how does the speed of those times compare with the speed of the present time in running trains?

A. I think it is very near the truth to say that cars are now a little more than twice as heavy as they were thirty years ago, and that the speed has very considerably increased in that time. I think it is safe to say that the speed has increased thirty-five or forty per cent., on the average, over that day.

2112 Recross:

Cr.-int. 74. If a wheel under a car, when the brake is applied, commences to slide, about how far do you think, under ordinary circumstances, it will slide before a flat spot begins to be worn on the periphery of it?

A. It commences to be worn immediately, on the moment of sliding.

Cr.-int. 75. How far do you think a sliding car-wheel must slide before the flat spot, which you say commences to be worn immediately, will become so much worn as to injure the wheel?

A. A good wheel is susceptible of a good deal of sliding. By "good wheel," I mean a wheel uniformly hard over the whole surface.

Cr.-int. 76. Take car-wheels as they have been on the average during the last twenty years, and then answer the question.

A. The question calls for a specific distance, and that will vary with all the varying conditions. A wheel will slip easier when the rail is wet and muddy than it will when it is dry and gritty. In that view of it, it is almost impossible to give any distance. It depends, also, upon the weight of the car and the condition of the rail.

Cr.-int. 77. Take, if you please, a dry rail, and a passenger-car of the average weight, if you know what that is, during the past twenty years?

A. You ask for a specific distance, and that would vary with every circumstance. I cannot answer the question any more specifically. I will state, further, that at the same time we tested several wrought-iron wheels of English make, and they experienced, probably, their proportion of sliding; yet it was never discovered that their sliding affected the tread in the least.

Cr.-int. 78. Do you know what was the average weight of passenger-cars upon first-class railroads between the first of January, 1850, and the thirty-first December, 1864?

A. I do not.

Cr.-int. 79. Can you give any approximate judgment about it derived from your railroad knowledge?

2113 A. I think I can.

Cr. int. 80. Please do so.

A. I weighed several passenger-cars about 1853, and they weighed eleven, twelve, and sometimes thirteen tons, depending upon their length; and from that time cars have been increased in ornament and strength, gradually running up to about twenty tons at the present day; and, judging from that gradual increase of weight that I know they have experienced, I should think that at the time spoken of cars would weigh fifteen or sixteen tons. That is my judgment.

Cr.-int. 81. Now, suppose that the wheels of a passenger-car, weighing fifteen tons, and running upon a dry rail, began to slide under the application of the brakes, and assume that the wheels are, as the question just above called for, of the average quality which wheels have had during the last twenty years, about how far, to the best of your judgment, must such wheels slide before the flat spot becomes sufficiently worn to injure the wheels?

A. I cannot answer that question.

Cr.-int. 82. Why not?

A. You speak of the "average quality" of wheels. There are a great many wheels that are very defective in their hardness. They have soft spots upon them, with little or no chill or crystallization in these spots, and if a wheel happens to slide upon this soft place, it will be injured almost immediately. If a wheel is an evenly hard chilled wheel, as all wheels ought to be, it will slide a very great way without any perceptible alteration in it at all. I have worn wheels for over four years without any replacement. Hence the difficulty of answering the question under any average condition. I cannot say how far a wheel can run.

Cr.-int. 83. Do you think that wheels that would wear four years without any replacement are average wheels, as car-wheels have been during the last twenty years?

A. No, sir.

Cr.-int. 84. Do you know about how long car-wheels of the average quality, which have been in the market for the last twenty years, will wear in passenger-trains, under ordinary circumstances, on first-class roads?

2114 A. I know it was the habit of the Hudson River road to exact a warrant for one year. They would frequently wear three or four years. You can draw your own inference of average from that. I cannot answer the question any further. I have never kept any statistics of the average wear of wheels.

Cr.-int. 85. Would they also frequently wear less than one year?

A. They would frequently give out in less than a year. In that case they were put back upon the makers as bad wheels.

Cr.-int. 86. In how short a time did they sometimes give out?

A. Almost immediately. Those immediate cases, however, were mostly cracks, detected flaws.

Cr.-int. 87. Do you know what a car-wheel of average quality at the present time is?

A. I am not as familiar with the wheels of the present time as I was formerly. I have paid but little attention to modern wheels.

Cr.-int. 88. For how many years were you familiar with car-wheels?

A. Well, from 1838 to 1854, and a good deal of the time since that, by my indirect connection with the wheel-makers, Barnum & Richardson.

Cr.-int. 89. How much of the time since 1854 have you been familiar with car-wheels?

A. Well, I will say all of the time. I have kept up my familiarity with them. I am almost daily seeing them, watching their actions, and discussing, and hearing discussed, their relative merits.

Cr.-int. 90. Do you know what was the average quality of car-wheels used by first-class railroads between January, 1839, and December 31st, 1864?

A. The average quality of the wheels was pretty fair, and I believe generally improving in their strength during that period.

Cr.-int. 91. Can you say approximately how long a wheel of pretty fair quality would have to slide on a dry rail, under a passenger-car weighing fifteen tons, before a flat place, commencing to be worn in it when it began to slide, would be sufficiently worn to injure the wheel?

2115 A. Well, I have found in my experience it varied very much with the nature of the ballasting of the road; that in sandy regions where the rail is liable to be gritty, it would wear faster than it would where the ballasting was grassy and weedy.

Cr.-int. 92. What is the usual ballast of first-class railroads?

A They generally desire good, substantial gravel, where it can be had; but they are sometimes compelled to take up with very dry and gritty sand. There are large tracts of country where gravel cannot be had at all, as, for instance, on Long Island. I will say the lower section of the Hudson River R. R. had no gravel within forty miles of New York, and a great deal of the New England territory is without gravel.

Cr.-int. 93. Take a road with gravel ballast, and give your judgment.

A. I will say in answer to that, that gravel contains more or less soluble material in it, which is very lubricating to the rail; a muddy mixture. It will vary with every varying condition I have mentioned. I cannot answer specifically the question as to time or distance.

Cr.-int. 94. Do you understand that the question asks you to answer it specifically?

A. I have so understood it.

Cr.-int. 95. Are you able to form any judgment whatever, under any circumstances, as to how far a car-wheel, under the conditions assumed, must slide before a flat place commencing to be worn when the sliding begins, will be so much worn as to injure the wheel?

A. I am not able form any judgment, nor do I believe it in the power of the human mind to form an exact judgment on this question. All the variations and conditions involve a sliding-scale.

Cr.-int. 96. Do you understand that you have been asked to form an exact judgment?

A. I do understand so.

Cr.-int. 97. You have said in your direct examination that in a car
having swinging bolsters, and having the Tanner brake, when the
2116 car is in motion, the forward truck draws towards the centre-lever,
and the rear truck draws away from it; and you have also spoken about the effect upon the trucks when the brake is applied to the car. Have you ever, yourself, tried the application of the brake under these circumstances, so as to be able to observe accurately the relation which the trucks assume to the centre-lever under these circumstances?

A. I have not.

Cr.-int. 98. You have also testified on your direct examination that, though there is a tendency upon the application of the Tanner brake to draw the rear truck towards the centre-lever, that tendency is not enough, in your judgment, to overcome the force tending to make the truck hang backwards. Do you consider that this characteristic in the Tanner brake (if it be in it) is sufficient to materially injure the Tanner brake for a practical brake?

A. I cannot say. When we consider what latitude is allowed all brakes with reference to unequal action upon the wheels, the Tanner brake tried by the same rule would not be materially affected.

Cr.-int. 99. Referring to your answers in your direct examination in regard to sliding wheels at high velocities, please state whether car-wheels may slide when the brake is applied to them, when the train has a velocity of twenty-five miles an hour.

A. They may be made to slide at that velocity. I have seen it done by the Creamer patent brakes, where the brake is applied suddenly. But the first part of this answer refers to hand brakes that are applied more gradually.

HENRY WATERMAN.

Deposition of William O'Brien.

Int. 1. Are you the William O'Brien who was examined in this case on September 23d, 1872?

A. I believe so. I don't know exactly the date. I believe I was here some time in September.

Int. 2. Since you gave your evidence on that day for the
2117 complainant have you operated the Springfield brake on Jennings' train?

A. No, sir; I have not. The last of my using the Springfield brake will be a year next June—I believe along the 5th June—until yesterday.

Int. 3. On what part of Jennings' train yesterday did you act as brakeman?

A. Well, when we left here I was braking between the passenger-car (that is, the second passenger-car from the rear) and the smoking-car at the Providence crossing. I broke on the Springfield brake on the smoking-car—the hind end of it.

Int. 4. Did you continue to brake on the smoking-car of that train through to Springfield at all the stopping-places?

A. No, sir; after that I went up upon the baggage-car and postal-car, where I formerly broke.

Int. 5. Did you brake on both cars at that time?

A. No, sir; I had only one brake—the forward end of the baggage-car.

Int. 6. On what car did you brake from Springfield to Albany?

A. On the smoking car, forward end.

Int. 7. Was the brake used on all the cars that had the Springfield brake on from Springfield to Albany?

A. I believe not. The brakeman who was with me (I didn't know the road) broke with me between the baggage-car and smoking-car; he used the baggage-car brake and I used the smoking-car brake.

Int. 8. Was the brake put up on the express-car next the engine?

A. I don't think it was; I didn't see anybody on it.

Int. 9. Then you wish to be understood that one car in the train with the Springfield brake on was not used at all between Springfield and Albany?

A. I believe not; I didn't see anybody on it.

Int. 10. What brakes were relied on to take the train through from Springfield to Albany?

A. The three Springfield brakes and the Hodge brake.

Int. 11. Name the cars that had the Springfield brake on.
2118 A. I cannot give the numbers; the postal car, the baggage car,
the smoking car, and one passenger carriage.

Int. 12. Do you know the number of the passenger car?

A. 123 I believe it was.

Int. 13. What was the number of the car that had the Hodge brake on?

A. I don't know; I believe it was 134. I am not used to the numbers of the cars.

Int. 14. What can you say as to the operation of the Springfield brake on the cars which you broke on from Boston through to Albany?

A. Well, the smoking car, when I took it, had a Springfield brake on, and I thought that it had not been used at all; it was quite stiff when I first took it; the hind end had been used by me some at the Providence crossing; the forward end had not been touched, I believe. I won't be positive where I did commence to use it. I think it was at Springfield that M'r Waterman told me to use the forward end of the smoking car.

Int. 15. Did the brakes get finally limbered up so that they worked well?

A. My brake worked so it was quite limber after we made two or three stops. I used to work it back and forth so as to limber it up. It was kind of stiff, and I am not very tall, and the shaft was quite high, so that I didn't have as good a purchase as I should if it had been as low as brake-shafts generally are.

Int. 16. Do you think that the wear of the brakes was taken up rather too short for good action?

A. Well, I think it was pretty short; when I first commenced to use it the chain was very taut.

Int. 17. What kind of stops did you make, as a general thing, over the whole road from Boston to Albany?

A. Well, from Boston to Springfield at some of the stations we made very fair stops; at some stations we did not; we ran by twice, I believe.

Int. 18. At what stations?

A. We ran by at Ashland and Spencer.

Int. 19. At all the other stopping-places you made good stops?

(Objected to as leading.)

2119 Int. 20. If you did not make good stops what kind of stops did you make?

A. I said at some stations we made very good stops; and there was another place we ran by called Schodack; I believe it was the last stop we made.

Int. 21. When you speak of running by, how many car-lengths did you run past the station where you ought to have stopped to make it a good stop?

A. Upon the western end I don't know anything about the stations anyway. I should call it a barn more than I would a station. I know we went by the stations; at least we went by so that they didn't back up to them. Why I make that remark, sometimes where there is baggage to take off or put on we have to back up when we go by.

Int. 22. Did you back up to any station?

A. No, sir.

Int. 23. Is the station which you called Schodack on an up-grade or a down-grade?

A. I cannot say, because I never was over the road before.

Int. 24. What is your opinion about it; do you think it was on a grade or on a level track?

(Objected to.)

A. Well, I cannot say; I never was over the road before; I don't think it was very much down-grade or very much up-grade.

Int. 25. Very nearly a level grade?

A. I should say so. It might be a down grade for what I know.

Int. 26. Where did you make the best stops, on down-grades or level grades?

A. We made the best stops on level grades. I never knew a train where they could make as good stops on a down grade as on a level grade.

Int. 27. Did you make good stops on the down grades?

A. We didn't go into the stations as fast. We didn't run by any stations only those three that I mentioned.

Int. 28. Did you make good stops all the way upon the western slope of the Green Mountains from the station called Washington to Pittsfield?

2120 (Objected to as leading.)

A. Well, I said we didn't run by. Making good stops and making the stops we made yesterday is two different things. I say we didn't run by. I was a stranger on the road. Perhaps what they would call good stops I would call bad stops.

Int. 29. You didn't run by the stations?

(Same objection.)

A. We didn't run by the stations.

Int. 30. In running the said train from Worcester to Springfield did you make what you call good stops at the several stations?

A. Some stations we did and some we didn't.

Int. 31. Which stations do you think you made good stops at?

A. Well, we made a very good stop with West Brookfield.

Int. 32. What do you mean by not making very good stops?

A. Well, drag into a station; let them brake up and then run by.

Int. 33. When you drag into a station it is evident you put on the brake too soon or too hard, isn't it?

(Objected to.)

A. In some cases, and in some it isn't.

Cross-examined by M'r Cozzens:

Cr.-int. 1. On this trip yesterday where you broke with the Springfield brake, did you, in making your stop, begin to brake any further back than you do in making stops with the Hodge brake?

A. Well, in some cases I did, for the very reason that I didn't know how the brake was, not having used it for so long. I didn't know whether I could put any dependence upon it or not or any other brake. If they had been my own cars it would have been different.

Cr.-int. 2. About how many times did you begin to apply the brake further back from where the stop was to be made than you did with the Hodge brake?

2121 A. Well, I did going into West Warren for one place, and into Brimfield I believe it was. They are both down-grades around curves.

Cr.-int. 3. Did you see anything upon this trial with the Springfield brake yesterday to induce you to change in any respect the testimony you gave in this case about the Springfield brake on the 23d of September, 1872?

A. Well, that is a kind of hard question.* This brake that I had yesterday had just come out of the shop; it was in the highest point, I suppose, of working order, though I don't know whether it was or not; but I noticed yesterday, when I first took this brake, it worked very well sometimes; but as I worked it longer, it seemed as though the slack was more changeable; it would not catch so quick.

Cr.-int. 4. And would not work so well?

A. Well, it required a great deal more muscle. I noticed in going into Schodack—in fact, I didn't have much chance to see where we were, but the fellow said we were on the station, and I commenced braking and broke as hard as I could, and when we went by the station I was braking.

Redirect:

Int. 34. In braking on the Boston and Albany road do the brakemen have to exercise their judgment as to where to put on their brake, or are they governed by the whistle?

A. They exercise their own judgment; at least I always do. I wouldn't give much for a man who does not.

Int. 35. Then I infer that it was lack of judgment in putting on the brake at Schodack which caused you to run by; you did not put it on quick enough?

A. How should I know where the station was? I never was there before in my life. I was not any more lacking in judgment than the other brakeman was; he said he would make a good stop.

Int. 36. You, of course, were not familiar with that station and with what was requisite to make a stop there?

A. I was never there before; I broke according to his orders.

2122 Int. 37. Which brake, the Hodge brake or the Springfield brake, could you form the best judgment as to where to begin to brake in order to make a stop?

A. The Hodge brake, by all means.

Int. 38. Nearly all your practice as a brakeman has been with the Hodge brake, has it not?

(Objected to.)

A. Yes, sir.

Int. 39. Did you or not find it difficult to judge accurately in reference to the place to apply the Springfield brake, from the fact that your mind was trained to the Hodge brake?

(Objected to.)

A. Well, as I said before, I didn't know the road. I suppose if I had had my own two cars with the Hodge brake, it would have been different.

Recross:

Cr.-int. 5. What was the name of this other brakeman you speak of who told you when to brake?

A. I cannot tell you, sir; I didn't ask his name, although he knew me very well; it was the forward man.

Cr.-int. 6. Do you know whether he was a regular brakeman on that division of the road?

A. Oh, yes, sir; he has been on there for a good while.

Cr.-int. 7. And on that train with the Springfield brake?

A. Yes, sir. I had to go by him. I didn't know about the road. It would have been different if I had known the road.

Cr.-int. 8. You say you are not familiar with the stations on the western division of the Boston and Albany road. Are you familiar with the eastern division from Boston to Springfield?

A. Yes, sir; I am.

Cr.-int. 9. How long have you been a regular brakeman on this eastern division?

A. It is five years last month, I believe, since I came on the road. I was off the road about a year, very nearly. I was sick a little while, and on the Eastern road.

Cr.-int. 10. Would you, as to this eastern division, rely upon your judgment as to where to begin to apply the brakes?

2123 A. Oh, yes, sir.

Cr.-int. 11. And yet, notwithstanding your familiarity with this division, you ran by stations yesterday with the Springfield brake?

A. Yes, sir.

Cr.-int. 12. Suppose, on the trial yesterday, you had had no car in the train with the Hodge brake on, but only car swith the Springfield brake on, do you or not think that the train would have run by many more stations than it did, having one car with the Hodge brake on?

A. Well, I don't know. I can't say as we would have run by, because we would have been more careful of the train; but I don't think we could have made such good stops, because we would have held the train slower, and slowed it down to the station.

Cr.-int. 13. You would have commenced to break up sooner?

A. Oh, yes.

Cr.-int. 14. Do you know how many brakemen are usually carried on that train?

A. Well, they have three from Boston to Springfield, and two from Springfield to Albany.

Cr.-int. 15. How many did they have yesterday?

A. Well, they had five from Boston to Springfield, and four from Springfield to Albany.

Cr.-int. 16. Did they all work at the brakes?

A. They all did from Springfield to Albany.

Cr.-int. 17. How many did from Boston to Springfield?

A. There were four of us. On account of not using the Hodge brake on this end, the fifth man did not work between Boston and Springfield.

Redirect:

Int. 40. Do you or not understand that the Hodge brake was not used at all between Boston and Springfield?

A. Yes, sir; that is what I understood. I did not see it used. I think it was used at the Providence crossing, but I won't be positive.

Int. 41. Then, if I understood you, the four brakemen operated each a Springfield brake from Boston to Springfield?

2124 A. Yes, sir.

Int. 42. And the three brakemen from Springfield to Albany operated each a Springfield brake, and one a Hodge brake?

A. Yes, sir.

Int. 43. Leaving a Springfield brake that was not operated at all?

A. Yes, sir.

Int. 44. But the four men did not do any more work than two men might have done had each man stepped over to the other platform?

(Objected to as leading.)

A. Well, four men can do more work than two can on a train, because they both brake together; those four brakes are coming right up snug. While a man is setting one brake he has not power to set another. If the brake ahead of him was the rear brake it would do well enough.

Int. 45. Is that the main object of the double brake—to enable a brakeman to brake on two cars?

A. Do you mean to say that one man can set two brakes as quick as two men?

Int. 46. No; but putting time out of the account, cannot one man set up two double brakes as hard as two men can, by stepping over to the adjoining platform, after he has put on one brake, and then putting on the other—give him all the time he wants?

A. Well, that don't do, going into a station, you know.

Int. 47. I ask you if he could?

A. I don't know. Perhaps the man setting the brake on this side may be stronger than I am, or set it up harder. Take a brake when it is new, and let a man set it; if there is too much damned paint on it, as there generally is, he can set the brake hard; but when the train starts he can't let it off; it will stick too hard. Now, take my two brakes; I can set them up pretty hard; perhaps some men could let them off, and some could not.

Int. 48. Do you daily set up two brakes, one on one car, and one on the car opposite?

A. Yes, sir.

Int. 49. Can you set up two brakes as tight as another man could with the same strength and skill as yourself?

2125 A. Well, I don't know about that; perhaps he might set it a notch harder than I could, and perhaps I would set it a notch harder than he could. It depends on what I was setting for.

Int. 50. Can you set up two brakes as tight as you can either one of the two, one right after the other?

A. I don't understand that.

Int. 51. Can you set up the brakes on two cars, opposite each other, one as tight as the other, having time?

A. Well, one might not work as well as the other; it might not hold so well.

Int. 52. Provided they are in equally good order?

A. Well, if they are both the same kind of brakes, may be I can, and may be I can't. Perhaps I may be a little stronger when I am on this brake than when I am on that; my wind is a little better.

Deposition of George H. Gardner.

Int. 1. Are you the George H. Gardner who was examined by the complainant in this case on September 21st, 1872?

A. Yes, sir; I don't know the day and date.

Int. 2. Did you state in the deposition then given that you would, if called upon, go on to Jennings' train, on the Boston and Albany road, and operate the brakes thereon, and report the result?

A. Yes, sir.

Int. 3. Have you done so?

A. I have, sir.

Int. 4. When?

A. Yesterday.

Int. 5. Will you now state in detail what car you operated the Springfield brake on, and with what results?

A. I operated the brake on car 123 from Boston to Springfield.

2126 Int. 6. Go on, and take the different stations in detail, and state the results as to whether you made good stops. At the stations, say where you ran by, and state the circumstances connected therewith.

A. Well, we started from Boston at five o'clock. Our first stop was at the Providence railroad crossing.

Int. 7. State what kind of a stop that was, in your judgment.

A. I think we made a very good stop there. We then went on to South Framingham, where we crossed the South Framingham and Mansfield road. We made the Know-Nothing stop there. I think we stopped very well there. We then dropped down to the station, dropped down very well; it is only a short distance. The next station was Ashland; we ran by that station.

Int. 8. Please state the condition of your brake on running by.

A. I had set the brake at three stations before arriving there, and when I set my brake there, I set it as hard as I could, but I could not keep my car away from the rest of the cars ahead of it.

Int. 9. On examining the brake, what did you find the condition of the chains? Had they wound uniform'y round the windlass? If not, why not?

A. There are two chains winding round the windlass, and I found that the upper one had caught on a nut that there was there, so that the chains had not wound up even. I found that one was drawn up very tight, and stepping down the steps and feeling under, I found that the other chain was not drawn up tight.

Int. 10. So that there was but little or no power on one brake?

A. There could not have been much power on the lower chain.

Int. 11. The other brake was obstructed by the chain winding over the nut?

A. That was some obstruction, I presume; but I had set the brake as hard as I possibly could set it.

Int. 12. Well, passing that station, proceed to the next, and so on through to Springfield.

2127 A. Well, I didn't mark anything very great in the change of the stops along until we came to Spencer. We stopped at Charlton, and coming down Charlton grade, we came round a very sharp curve, over a dry bridge, or street bridge, and I held the slack of the train a little there, and held the brake with my hand. I kept the cars as steady as I could. I didn't set the brake hard enough as I considered to check the train any; merely did as I have done before when I worked on the road, held the slack of the train to keep the cars steady.

Int. 13. You did that with this brake?

(Objected to.)

A. I did that, after we passed that curve—that is all curve, a sort of reverse curve there; we crossed a highway somewhere east of Spencer. When I used the Springfield brake on the train before, I always made calculations to set that brake up as hard as I could there; that is nearly a quarter of a mile, I should think, from the station. I always commenced to brake a great deal sooner with this Springfield brake than with the Hodge brake, and I did yesterday. I commenced sooner yesterday at that place to set my brake as hard as I could, but I could not do any more than stand and look at it. I had orders not to use the brake on the other car, and we ran by the station.

Int. 14. How much?

A. Well, what I call running by a station is running by so that if there is baggage to get out or put in, they have to go down into the ditch, or back up, to get it into the car.

Int. 15. Did they have to go down into the ditch to put the baggage into the car this time?

A. I do not know as there is any ditch at that station; but when we have five cars, the rear car comes very near the end of the platform. We calculate to let the cars run up so that the passengers in the rear car can have the benefit of getting out on the platform. The rear car ran down nearly opposite the station; probably two cars further than as a general thing.

Int. 16. Now proceed to the next station, and tell us what the stop was, and so on.

A. I noted no great difficulty in going on to Springfield.

Int. 17. In going down the grade this side of Springfield, did you set the brake to go down on car number 123?

2128 A. Yes, sir; lightly.

Int. 18. Was any other brake applied for that purpose?

A. Not that I know of. I was on the rear car, and I had no way of knowing what they were doing.

Int. 19. Is it usual to steady the train by using the brake on the rear car?

A. Yes, sir.

Int. 20. After leaving Springfield, please state what position you took on the train, and what labor you performed, and on what car.

A. After we left West Springfield, I forget just exactly where I was, I went up ahead on the smoking-car, stopped there a few moments, and then I went back to the rear of the train, after crossing the river at West Springfield. I was never beyond Springfield, and knew nothing about the stations, nor where they stopped.

Int. 21. After you came to the mountain, what did you do about letting the train down the western slope?

A. I think the station they called Washington is on the summit. I noted that when we got up to the top of the summit, they pitched down, and they didn't have but a short time to run before they stopped at a station.

Int. 22. Tell us how you stopped, and what you did towards stopping.

A. I didn't have anything to do with stopping at that station, but I noticed that M'r Taylor, the brakeman on the rear car, set up the brake on car 123, and stepped over on to the other car, 134, and undertook to set that brake (the Hodge brake) up; somehow or other the chain wound up over the nut, and went above, so that he could not set it, so he let it off, and commenced to wind it up again, and got it right that time; and I heard the conductor ask him how he came to run by, and he explained how the brake caught, and he could not set it; so I judged we ran by.

Int. 23. The reason why you ran by was because the Hodge brake was not used?

(Objected to.)

A. Yes, sir.

Int. 24. Did you take a position on the rear of the train and set up the brake, and through its agency hold the train down the western slope?

2129 A. I was told by M'r Waterman to go back on the rear of the train and set up the brake as hard as I could set it, going down the grade, so that he could see how it worked. I went back and set the brake up as hard as I could; whether I took the slack of the train or not I cannot say, because I had no way of seeing; I was on the rear of the train.

Int. 25. But M'r Taylor, after you applied the brake, signalled to you to let off the brake?

A. He signalled to me to let go.

Int. 26. What did you infer he meant by signalling to let it go?

A. I didn't know whether we had got to the foot of the grade, whether he wanted us to go faster, or what it was; but he made the signal, and I let go about half of it.

Int. 27. Did you infer the brake was braking too hard for the proper speed of the train?

A. I presumed from his making motions that he had orders from M'r Waterman to let them go. After he gave me the motion to let the brake go, I let the brake off about one-half, and M'r Waterman came through to see how it was. He wanted to know how it was, and I told him I had eased it off, and then I set it up as hard as I could again.

Int 28. And by so doing, did you or not ease the train down properly into the station at the foot of the grade?

A. I cannot answer that, because I was not acquainted with the road and do not know where the foot of the grade was; but I set the brake up the second time as hard as I could, and held on the brake until I judged I was pretty near on a level, and let it drag somewhat, to see if the engineer would whistle "off brakes," but as he didn't whistle off brakes, I let go the brake, and went through the car to the other end.

Int. 29. Did you let it off from the fact that your judgment told you it should be let off?

A. That was the opinion I had of it. My judgment was that I had no business to drag the brakes when there was no need of it, without I had orders to.

2130 Int. 30. If I understand you, your reliance was made entirely on the Springfield brake on car 123, to take the whole train down the western slope of the Green Mountains to the foot of the grade?

A. Steady the train down.

Int. 31. Well, after you got to Pittsfield, what further labor did you perform on car 123 from thence to Albany?

A. I took no further part in it on that car. I did not know the stations, nor how they stopped. M'r Taylor preferred to stand on that car, so that he could look out and see where they were going. We went into a number of stations, and he told me where there was a down grade to the stations, and when he commenced to brake, I stepped over on the opposite car, 134, and set that brake, and he made me motions when to brake up hard. I set it up a number of times as hard as I could set it.

Int. 32. Did you find any difficulty in winding the two chains upon the windlass shaft on the rear end of 123?

A. No, sir.

Int. 33. Did you operate the Springfield brake upon either of the other cars from thence to Albany?

A. No, sir.

Int. 34. Then your services were virtually closed after you took the train down the grade this side of Pittsfield?

A. No, sir; I consider that I was on duty all the way through; I watched M'r Taylor's motions, and used the brake.

Int. 35. I mean, you did not use the Springfield brake after you took the train down the western slope of the Green Mountains?

A. No, sir.

Cross-examined by M'r Cozzens:

Cr.-int. 1. How perfectly do you think the Springfield brakes were adjusted on this train, when the train started?

A. I think when we started from here yesterday, they were adjusted just as perfectly as they possibly could be.

Cr. int. 2. About how soon do you think it was, after leaving Boston, that the chains began to get perceptibly slacker?

2131 A. I don't know anything as to that. We made our three stops this side of Ashland, and then the brake worked badly there, by the chain catching over the nut. After that, I set the brake up so as to get the slack of the chains, and took my pencil and marked it on the ratchet—the Springfield brakes got out of kilter so many times when I have used them—to see if there would be any change in them, after they had been so properly adjusted between Boston and Albany. Well, I worked the brake along until I got to Springfield. When I got to Chester, M'r Taylor set the brake up, and turned it just one-half of a turn more than what I had it when I left Ashland. I asked him if he had got it set up as hard as he could, and I stepped over and took hold of it, and set it up one notch further; and I didn't strain myself nor work any harder than I did at Ashland.

Cr.-int. 3. That shows, does it not, that the chain had got slacker that much between those points?

A. Yes, sir.

Cr.-int. 4. According to your experience with the Springfield brake, does it work better or worse as the chains get slacker?

A. In my judgment I should think they would not work so well. The longer they work them, the more they get out of adjustment. To have them work first-rate, they ought to have a man on the train all the time to look after them, and adjust them—keep them in order.

Cr.-int. 5. According to your experience in this trial yesterday, did or not the Springfield brakes hold the train, on the whole, as well as the Hodge brake would hold the train under the same circumstances?

A. No, sir; I don't think it did.

Cr.-int. 6. How long an experience have you had as a regular brakeman with the Hodge brake?

A. I have been braking with the Hodge brake all the time for about six years. There were four months that I was off duty at one time, and I was freight brakeman part of that time.

Cr.-int. 7. About how much time have you been regular brakeman on passenger trains on the Boston and Albany R. R., eastern division, where the brake used was the Hodge?

2132 A. I was on a number of different trains on the Boston and Albany road. I was on—I can't say the exact time. I have done a great deal of spare work, going out on any train that they wanted me to. I guess I was employed by the Boston and Albany corporation about a year, as near as I can recollect.

Cr.-int. 8. Did you observe anything in the results of the Springfield brakes yesterday, to lead you to change in any respect the testimony you gave in regard to this brake in this case on the 21st of September, 1872?

A. I did not see any change more than this: I saw that there had been some improvements made on car 123 since I used it. When I used the brake on car 123 before, they had these old-fashioned brake-shoes on, and the brake chains on the car were between fifteen and sixteen inches long. I noticed yesterday that they had got new patent shoes on, and that they had put on longer chains. I did not measure them, and can't say how much longer. I should say somewhere in the neighborhood of three feet in length, in all.

Cr.-int. 9. Would not this greater length of chain prevent the end of the rod to which the chain is attached being brought up so as to come against the windlass shaft when the chain was pretty slack and the windlass wheel was turned?

A. I don't think it could be brought up to the windlass shaft as it was yesterday, without breaking somewhere and staving it all to pieces.

Cr. int. 10. About how long, to your recollection, was the chain as it was when you used the Springfield brake before on this same car?

A. Between fifteen and sixteen inches.

Cr.-int. 11. How much, if you know, was the Hodge brake used on this train in going from Boston to Springfield?

A. It was not used at all, to my knowledge.

Cr.-int. 12. How much was it used between Springfield and Albany?

A. I noticed they used it at about every station.

Cr.-int. 13. In your judgment would or not the train have run by more stations than it did if the Hodge brake had not been used?

2133 A. Yes, sir; I think, under the same circumstances, and the men commenced braking as they did yesterday, if they had had car 124, with the Springfield brake on it, as I left it last July, instead of 134, with the Hodge brake on it, they would have run by a great many stations.

Cr.-int. 14. You say you are familiar with the eastern division of the road?

A. Yes, sir.

Cr.-int. 15. Were or not the Springfield brakes on this train yesterday commenced to be applied sooner in stopping at stations, than the Hodge brake is on the same division, at the same stations?

A. I think they were. I used my power and judgment yesterday, as nearly as I could, the same as I did when I ran on the train as an employee of the road last July.

Cr.-int. 16. And that was to apply the brakes sooner than if you were using the Hodge brakes?

A. In my judgment I applied the brakes to stop the train as near to the station as I could.

Cr.-int. 17. You do not exactly answer the question, whether that led you to apply the Springfield brake sooner than you would the Hodge, under the same circumstances?

A. Yes, sir; I always did commence to apply the Springfield brake sooner than the Hodge. I could always depend upon the Hodge brake, when I was on a train that had that kind of brake on it.

Cr.-int. 18. Did you feel as though you could depend upon the Springfield brake?

A. Well, I couldn't say that I did.

Cr.-int. 19. With which brake did you have to work harder in applying the brake on the whole, the Springfield brake, as it was on the trial yesterday, or the Hodge brake, as you have been in the habit of using it?

A. The Springfield brake works the hardest, and always did, ever since I had any experience.

Cr.-int. 20. And was this working harder true of it yesterday, also?

A. I did not see but it was as hard work. I could lay out all the power I had on the brake yesterday, as usual.

2134 Cr.-int. 21. You mean that it did work as hard yesterday as usual?

A. Yes; at the first of it, I think it worked a little harder, because there was no slack of the chains to speak of at all. Everything was stiff and adjusted right up. It worked very hard.

Cr.-int. 22. With which brake can you best take the slack of the train, the Hodge brake or the Springfield brake?

A. The Hodge brake. When using the Springfield brake I never had any fault found by the engineer about yanking the train, or stopping too quick; but I have been on trains, when I had a full train with the Hodge brakes, where I have had considerable growling about yanking the train and taking the slack too quick.

Cr.-int. 23. In your judgment as a brakeman, with which brake on the rear car of the train, in this trial yesterday, could you have best taken the slack of the train, the Springfield or the Hodge?

A. With the Hodge. No man of common sense would question the power of the Hodge brake against the Springfield brake. You have not got the power in the Springfield brake to apply it; you have not got the muscle. If you had a man about four times as heavy as I am, he could set the Springfield brake about as hard as I can set the Hodge brake.

Cr.-int. 24. According to your experience on this trial yesterday, as to the stops or slackness of the train, where you applied the brakes between Boston and Springfield, how well, on the whole, were you able to take the slack of the train with the Springfield brake?

A. I cannot say we took the slack of the train at all, and I can't say but what we took it every time. All the chance I had to judge of taking the slack of the train was from the car I stood on.

Cr.-int. 25. Between Boston and Springfield, how well were you able, on this trial yesterday with the Springfield brake, to keep the car you were on off of the car ahead of you?

A. As a general thing, I judge that I held it pretty well; I kept the car back, kept the slack between the cars up; but as to how much I was holding, I couldn't say.

2135 Cr.-int. 26. Were there or not several times when you noticed that the car you were on ran against the car ahead of you, when you were applying the brake?

A. I noticed that at times. I can't say whether that was owing to the brake that I was using not holding, or because there was power ahead, holding it quicker than I could.

Cr.-int. 27. When you used the Springfield brake before on the Boston and Albany road, how well were you able to take the slack of the train, or keep the car you were on from running on the car ahead of it when you applied the brake?

A. I noticed, when I was using the brake before, as a general thing I would set my brake as hard as I could, very hard, and I would think I was doing a pretty good business at the time; but some brakeman ahead would come along and say, "Well, where were you; why weren't you braking back at such and such stations?" "I was braking for dear life; why weren't you braking?" "Well," he would say, "you never took the slack away from me." I always calculated to do the best I could with it under all circumstances.

GEORGE H. GARDNER.

BOSTON, *April* 19, 1873.

WILLIAM O'BRIEN recalled.

Cross-examined by M'r Cozzens:

Cr.-int. 18. Please state whether you recollect any incident in relation to the train Thursday, going down the grade at Dalton, in reference to the effect of the Springfield brakes upon the cars; if so, please state what it was.

A. Well, in going down, before we got to Dalton, M'r Waterman came to me and told me not to touch any brake going down hill, and told the other brakemen so. When we left Dalton the slack was taken off the train, the shackles were straightened out, and when we got down a little ways the bunters came together—the draw-bars—between the smoking-car and the baggage-car. I was standing on the forward end of the smoking-car. The regular brakeman (Gardner) was standing on the hind end of the baggage-car; that was the

2136 next car to me. He made some remark about his not having the slack of the train, and about that time the slack was taken again, and they came together again, and M'r Waterman came out on the platform to me, and says he, "You are not braking up, are you?" Says I, "No, sir;" and soon after we stopped at a station—I forget now the name of the station—on the road below Dalton.

Cr.-int. 19. At this time, did M'r Sayles come through the train to where you were standing?

A. Yes, sir; M'r Sayles came through and made a remark to me; he asked me if Gardner took the slack. Says I, "No; he can't take it." That is, he asked me if he held the slack, and I made the remark in this way: says I, "Damn it, he can't hold it."

Cr.-int. 20. Hold it with what?

A. With the Springfield brake.

Cr.-int. 21. On the whole, how well do you think these Springfield brakes worked, as compared with the way they worked when you were on the train with them before?

A. In my judgment, I should not think that No. 123 worked so well as before it was fixed, because, at the time I broke on the train, it was an every-day brake, and there was no more care taken of it than there was of any brakes; but yesterday morning it was in perfect order; it had been fixed on purpose for that occasion.

Redirect:

Int. 52. Where is Dalton Station?

A. It is on the mountain, but I cannot tell where, because I am not acquainted with the road. I could not tell Dalton Station now, unless I saw the name of it on the station. They told me that was Dalton after we left the station.

Int. 53. Is it not immediately below the summit, running down from Washington to Pittsfield?

A. That is what they told me; that it was going down grade. After we left Washington, they said, "It is going down grade now," but not being acquainted with that division of the road, I cannot tell the grades.

2137 Int. 54. How many cars were between the platform where you stood and the rear of the train?

A. Three cars.

W'M O'BRIEN.

Henry Waterman recalled.

Int 1. Have you any remarks or explanations to make in reference to the evidence just give' by M'r O'Brien?

A. Where the occurrence took place was near the commencement of the heavy grades going westward over the Green Mountains. Just at that time, as I stated yesterday, M'r Taylor, having charge of the train, notified M'r Gardner to let the train run faster; and M'r Gardner also testified to that. I will state that in all the running down grade yesterday, I consulted M'r Taylor as to the speed of the train. I inquired of him several times if he let the train run that speed, if that was the speed of his train, and he said, "Yes, no more brakes necessary." (Counsel for the complainant objected to the statement of M'r Taylor.) I was controlled by M'r Taylor's judgment as to the speed of the train.

Int. 2. If I understand you, the running of the train together, as testified to by M'r O'Brien, was in consequence of the brake being let off by M'r Gardner to increase the speed.

A. That was the result of it.

Int. 3. Did Gardner thereafter take the slack of the train and hold it at an increased speed?

A. He did, below that, and held it quite hard.

Int. 4. Was there, from your observation, any difficulty in holding that train down that grade with the Springfield brake on car 123 in the rear operated by M'r Gardner?

A. The car, as I before stated, held three cars of the train on the high grades.

Int. 5. During the whole time of the passage of this train from Boston to Albany, was M'r Sayles, the complainant in this case, present, and advancing his views to M'r O'Brien and to M'r Gardner; and did he also, on returning from Albany, continue to present and press his views upon these men whenever he could get an opportunity, in your presence?

2138 A. M'r Sayles was present continually, noticed almost everything that occurred, consulted freely with me, advanced his views to me, discussed fully the merits of his brake, as an advocate, and also in the presence of both of these brakemen; and I thought very efficiently, and told him so at the time.

Int. 6. Did he, in your presence, attempt to run down the Springfield brake and set up the Tanner brake?

A. He used every disparaging epithet that could be applied to the Springfield brake, and to extol the Tanner brake.

Int. 7. And did the said Sayles, after the said O'Brien had been on the stand yesterday, have conversations with him when he left the stand in this room, and thereafter put him on the stand to be questioned?

A. I do not recollect as to the conversations.

Int. 8. Did he talk with them? I don't ask what he said.

A. I observed whispering between them.

Int. 9. And he did thereafter put him on the stand?

A. He did.

Int. 10. Since that recall, has he had the same witness in here this morning and on the stand again?

A. He has.

Cross-examined by M'r Waterman:

Cr.-int. 1. How do you know that M'r Taylor notified M'r Gardner to let the train run faster, as you testified in your first answer just now?

A. I saw him do it.

Cr.-int. 2. Where was Taylor standing, and where was Gardner standing, when Taylor so notified him?

A. Taylor was standing on the front platform of 123, looking into the door; Gardner stood at the back door, looking toward him, and he made a motion, waving his hand. I inquired what it was for, and he said it was to take off the rear brake. I went through the car immediately and inquired of M'r Gardner the condition of the brake, and he said he had it half off; M'r Taylor had signalled him to take it off.

2139 Cr.-int. 3. Where were you standing at the time that the bunters of the smoking-car, on which O'Brien was, and the bunters of the baggage-car, upon which the other brakeman was, came together?

A. Immediately after the waving that I have spoken of, near Dalton Station, I went forward, and I found that the bunters at the front end of the third car were striking against the other, and I immediately consulted M'r Taylor, if he wanted the train to go as fast as that, and he says, "Yes, we let her run here."

Cr.-int. 4. How do you know that at the time you reached the place where O'Brien was and saw the bunters together, the brake of the rear car was not being applied?

A. I was passing back and forth incessantly on that train, watching all the actions; and I ran from one end of the train to the other, making inquiries at every stage of the progress. I know it was just before going into Dalton Station that this slacking off of the brake took place; and

I also know that below Dalton Station, where M'r Gardner put on his brake hard (the point which M'r O'Brien has mentioned between the two cars), was just at the point of slackness. Just what I stated yesterday. The three cars were held by M'r Gardner's brake, the Springfield brake, on 123.

Cr.-int. 5. Will you say that at the time you stood on the platform where O'Brien stood, and saw the bunters of these two cars together, the brake of the rear car could not have been applied?

A. I was with O'Brien several times, and I make my answer, of course, taking the position stated by M'r O'Brien as near Dalton Station. I know at that time the brake was slacked on the rear car.

Cr.-int. 6. Might not the brake of the rear car have been applied between the time that you, as you say, left the rear platform of the rear car and reached the platform where O'Brien stood?

A. It might have been done, but it was entirely outside of all instructions and outside of the system of the experiment.

HENRY WATERMAN.

2140 *Deposition of Benj. C. Read, recalled.*

Examined by M'r Whipple:

Int. 1. I think you stated, in your deposition last August, that you were in the employ of the Boston and Lowell Railroad Company; are you still so employed?

A. No, sir.

Int. 2. When did your connection with said company cease?

A. The fifth of this April.

Int. 3. Please look at Defendants' Exhibit, Springfield brake, No. 2, and state whether the brake in said exhibit is the same as the one applied to four cars of the Boston and Lowell Railroad, under your direction, as superintendent of the car department of that road?

A. Yes, sir; the same.

Int. 4. You will please further state how you adjusted the long and short rods of said brakes to each other?

A. I adjusted the length of the rods by means of the turn-buckle.

Int. 5. The brake having been adjusted by means of the turn-buckles, that is, so far as connecting the rods with the truck-levers and the windlasses of the car was concerned, was any further adjustment in this respect necessary?

A. No, sir.

Int. 6. As the brake shoes wore away by use, how did you take up the wear?

A. By tightening the rods on the brake-bars and shortening the rod equally all round.

Int. 7. Then, after the brake had been adjusted properly, by means of the turn-buckles, you took up the wear by a uniform turning up of the nuts on the brake-bars, didn't you?

(Objected to, as leading.)

A. Yes; a uniform shortening of all the nuts throughout.

Int. 8. If you took up an eighth of an inch on one bar, how much did you take up on all the others?

A. We calculated to take up the same, the equivalent on the whole of them.

2141 Int. 9. Was it any more difficult to take up the wear of the brake-shoes on this Springfield brake than on any other brake?

A. Why, yes; it was more difficult, because there were twice as many nuts to take up; otherwise, there was no more difficulty.

Int. 10. That is, it required a little more time to take up the wear on the Springfield brakes than it did on any other brake? Is that it?

A. Yes, sir.

Int. 11. In what train were the four cars equipped with the Springfield brake put, and who was the conductor and who the brakeman?

A. It was known as the Lowell train; Blood was the conductor, and Emerson was one of the brakemen, and Wing the other.

Int. 12. Do you know M'r John McAllister, who was formerly in the employ of the Boston and Lowell Railroad; and if so, what were his duties while so employed?

A. He worked on general car repairs.

Int. 13. As a general rule, was it his duty to attend to the adjusting of brakes, and such other repairs as were necessary about the cars?

A. No, sir; he had nothing to do with it specially.

Int. 14. Under what circumstances was he called to perform such duty?

A. Occasionally, when one of the men was out sick, he would be sent to the car-house to take his place, perhaps for a day or half a day.

Int. 15. How came it that he was employed to look after the brakes the week that the Springfield brake was under trial in Blood's train, for the purpose of determining its capacity to stop the train on time?

A. He was not employed for that. Occasionally he was sent there to look the train over and take the brakes up, with others. Sometimes he would do it. There were three other men who occasionally did it.

Int. 16. Who did take charge of looking after the brake at that time, and at any time previous and thereafter?

2142 A. Well, that was my duty.

Int. 17. With what success did he meet in looking after the Springfield brake what time he was employed for that purpose?

A. Very poor success.

Int. 18. For what reasons?

A. He did not understand the nature of keeping it in order or altering it. He would alter one thing, right or wrong, and then he would send for me to come and regulate it.

Int. 19. To the 12th int. put to said McAllister, which read as follows: "Did you have to adjust the Springfield brakes on those four cars during that trial week, and if so, how often?" He answers, "Every time they came in; that is, every time they came over into the car-house; of course, when they came into the depot, I was not there to look after them." Did he have entire charge of this matter, as he has herein stated?

(Objected to.)

A. No, sir; I sent two other men; some days I sent three men there. There was but very little time to do anything to the train. The train was in the house some mornings not more than twenty minutes.

Int. 20. He has stated, in answer to the 15th int., which is as follows, "How often do you say he has adjusted them," (that is, the Springfield brakes), that he adjusted them "once a day?" Was that necessary?

A. Well, we looked them over every day, whether it was necessary or not. We endeavored to keep them in good order.

Int. 21. Were you in the habit of looking over the cars having the Hodge brake on every day?

A. They are all looked over every day, every trip they come into the house, to see that the brakes are proper and correct.

Int. 22. Are you under the necessity of taking up the wear of brakes every day?

A. No; it don't require it every day on any brakes; no faster than the iron wears away on the shoe.

Int. 23. To the 17th direct int., which reads as follows: "About
2143 how much time did you sometimes have to spend during this trial-week
adjusting these Springfield brakes?" He answers, "Well, if I knew how long that train was in, I could tell; for some days, almost every day during that week, I was out there from the time they came in until they went out." Then int. 18 was put, "You were at work adjusting all the time"? His answer is, "Yes, sir." What have you to say to this answer?

(Complainant's counsel objects to this species of questioning as improper.)

A. Well, the train arrived in Boston at five minutes past eight; it waited for another train to get out of the way, and then came over to Cambridge. It generally arrived there from twenty to thirty minutes past eight; and then the train stood from fifteen to twenty minutes, was hauled out of the house again, to shift another car into the train, and left the car-house from ten to twenty minutes past nine. That would make less than one hour that the train stayed in the house, including hauling it in the time.

Int. 24. Int. 20 reads as follows: "Did you have anybody helping you adjust these Springfield brakes during this time"? He answers, "Yes, sir." Int. 21 reads as follows, "Did you, when, as you have stated, you were adjusting those brakes all the time from the time the train came in until it went out, always get the adjustment finished?" Answer, "No, sir." Please state whether, as would appear by this evidence, all the men, including McAllister, were engaged in adjusting these brakes, and failed to do it even then?

A. They were employed all the time the train was in the house, and for the lack of judgment to adjust them, they could not do it.

Int. 25. Who did do it?

A. I very often had to go and do it myself. By spending five minutes, I would adjust the whole of it.

Int. 26. To the 30th direct int., which reads as follows: "Now suppose that all the cars belonging to the Boston and Lowell Railroad, which run on passenger trains, were equipped with the Springfield brake, how many men do you think it would take to adjust those brakes properly?" His answer is, "I should think it would take about fifteen or twenty." What is your judgment on that point?

2144 A. I should consider that was a wrong opinion. Three men
would do all the work and take care of the trains as well as they would with the Hodge brake. They would have to adjust it oftener.

Int. 27. The 31st int. read as follows: "How many men are there now employed on the Boston and Lowell Railroad, inspecting and looking after the cars and adjusting the brakes?" The answer is, "We have only got three men, I believe, in the car-house to look after the whole of the cars and adjust the brakes." That is correct, is it?

A. Partially correct.

Int. 28. Wherein it is not, please make the necessary correction?

A. Well, there were other duties that they performed, shifting trains, shifting wheels under the cars, and doing general repairs. It is about the labor of two men to look the train over. Some days there would be more work than ten men would do; other days, one man would do all the repairs; but two men generally looked the train over.

Int. 29. In his answer to the 31st int., he says: "They don't have to touch one of these other brakes once in a dog's age, without it is to put on a brake-shoe." He is then asked, "What brake do you refer to when you say 'these other brakes?'" His answer is, "The Hodge brake." Is that so?

A. That needs less care than any other brake there is running. It takes care of itself better than any other.

Int. 30. The 44th int. reads as follows: "In your opinion, as a railroad man, how would the Springfield brake answer for cars that have to run as far as the sleeping cars do, namely, from Boston to Montreal"? Ans. "I don't think they would answer very well." Int. 45. "Why not?" Ans. "Because, by the time they had run up there and back again they would have got pretty well shaken to pieces. I should not think there would be much of them left, the way those worked." Is there in the Springfield brake any more liability to be shaken to pieces than any other brake, if the nuts are all properly tightened up?

(Objected to.)

2145 A. If it is put on properly, as it should be, and as it is in the model, and the nuts well screwed up, it would run as long as any other brake with the nuts in the same condition. There is nothing in the operation or the wear of the brake that would loosen the nuts any quicker than on the Hodge brake.

Int. 31. The 46th int. reads as follows: "To what do you refer when you say, "the way those worked"? Ans. "The Springfield brake that was on Blood's train, for sometimes when they got in, the bolts on the connecting rod from one brake to another would be worked loose and be half-way out, almost all of them, sometimes." Was that so?

A. He had reference to the check-nuts on the turn-buckles. It was immaterial whether they worked loose back or forth. The turn-buckle would not turn more than one or two turns in going from Boston to Lowell and back.

Int. 32. Then he did not refer to the nuts on the brake-bars?

(Objected to.)

A. I don't think he did.

M'r. COZZENS. You don't know anything about what he refers to, do you?

WITNESS. No; I don't. On one particular occasion, I know he referred to those nuts.

Int. 33. The 47th int. reads as follows: "Did you ever have any difficulty with those Springfield brakes on Blood's train in adjusting them so that they would operate equally?" Ans. "Yes, sir; I couldn't do it." Did you find this to be the fact, in your own experience?

A. It is no more difficult to adjust those to operate well than any other brake.

Int. 34. Did you find out that he could not do it?

A. Yes, sir; he hadn't brains enough to operate them properly, most of the time.

Int. 35. What were his personal habits, which might affect his brain?

A. That question would affect his character.

Int. 36. In other words, was he given to strong drink?

A. That was the cause of his being discharged; his intemperate habits.

Int. 37. To what extent was he addicted to intemperance?

A. A large portion of the time he was partially intoxicated, particularly when he had any money to get it with.

2146 Int. 38. Had he been in the employ of the company previous to the time when he gave this evidence?

A. I employed him about three years ago, and he was so intemperate that he did not feel on an equality with the other men in the shop, and he left, and was gone perhaps a year; then he came back, and I hired him again. This last time he worked probably a year and a half up to last December. He was discharged last December for intemperance and neglect of his work, brought on through intemperance.

Int. 39. He says, in answer to the 48th int., "Say one brake hung off from the wheels two inches, and the other half an inch or an inch—when I tried to bring up the one farthest off as near up as the other one was, I would bring the one that was nighest close up, and the other one would not be up close enough." Was there any time when the shoes stood off two inches from the wheels?

A. I should think not. There was no necessity for it. If he could see what he was about, he could adjust them equally to the wheels.

Int. 40. Int. 49 is, "How often did you have such a difficulty as this?" Ans. "Well, as often as I had a mind to go to work at it to do it." Did this difficulty grow out of his want of understanding the proper way of adjusting the brake, or was it in the brake itself?

A. It was in the want of his understanding the proper means of arranging it and adjusting it.

Cross-examined by M'r Cozzens:

Cr.-int. 1. Is your recollection perfectly distinct of all the circumstances attending keeping the cars which had the Springfield brake in order during this trial week on the Boston and Lowell Railroad?

A. It might not be, on all the circumstances.

Cr.-int. 2. How much of the time during that week did you yourself do anything about adjusting the Springfield brakes on those cars?

A. Perhaps I might have gone up there every day. It was my business to go through the car-house and see that the work went right and properly. I might have gone there every day.

2147 Cr.-int. 3. The question is not what you might have done, but what you did?

A. I would say that I did go through the car-house every day. My place was at the lower end of the shops.

Cr.-int. 4. How much did you do, during that week, towards adjusting the cars that had the Springfield brake on them?

A. I directed the work.

Cr.-int. 5. How much time did you spend in that?

A. It might not have been much time, because the train was not there but very little of the time. It might have been ten or fifteen minutes every time I was there.

Cr.-int. 6. How often during that week were you there ten or fifteen minutes at a time?

A. Well, nearly every day.

Cr.-int. 7. What part of the day was it?

A. It was from half-past 8 to 9 o'clock—some time intervening. Sometimes the train was in at half-past 8, and then it would not be in until a few minutes before 9. It was very uncertain what time that train got into the house. We could not do anything to it until it got into the house.

Cr.-int. 8. Were you there at any other times of the day when that train came in, except about half-past 8 or 9?

A. There was no other time it was there except that time. It did not come over to Cambridge except in the morning.

Cr.-int. 9. How many days of this week will you swear that you were in that car-house, directing the adjustment of the brakes on those Springfield-brake cars ten or fifteen minutes at a time?

A. I could swear I was there five days. That would except Monday.

Cr.-int. 10. You mean you were there every day in the week, except Monday, ten or fifteen minutes, directing the adjustment of the brakes on those Springfield-brake cars?

A. I think I was.

Cr.-int. 11. Will you swear to that?

A. So far as my recollection will extend, I could swear to it.

Cr.-int. 12. How clear is your recollection about it?

A. Well, as clear as it was a part of my duty, and if I performed my duty I was there.

2148 Cr.-int. 13. You mean, then, do you, that the reason why you think you were there these five days was because it was your duty to be there?

A. Yes, sir.

Cr.-int. 14. You do not positively recollect being there?

A. I do some days recollect positively being there.

Cr.-int. 15. How many days of that week do you positively recollect being there, that you are now willing to swear to?

A. As I said before, I should be willing to swear I was there five days.

Cr.-int. 16. Will you swear that you were there five days, as a matter of positive recollection, without any reference to its being your duty to be there?

A. I couldn't swear to that.

Cr.-int. 17. How many days will you swear you were there during that week?

A. Five days, I told you before, as far as my recollection would go.

Cr.-int. 18. I again ask, then, will you swear that it is a matter of positive recollection now, that you were there five days during that week?

A. With the same proviso to it, I do.

Cr.-int. 19. What is the proviso you mean?

A. To the best of my recollection.

Cr.-int. 20. Then you mean that you cannot swear positively, do you?

A. I said before, I could not swear positively.

Cr.-int. 21. During the days you were there during that week, will you swear that you stayed ten or fifteen minutes at a time, directing the adjustment of those Springfield brakes?

A. Yes, sir; I could do that.

Cr.-int. 22. It took you, did it, the whole of the time that you spent in the car-house during these days of this week to superintend the adjustment of the Springfield brakes on those cars?

A. No, sir; it did not.

2149 Cr.-int. 23. How, then, is it that you just stated that you spent ten or fifteen minutes a day, during these days, in the car-house, in superintending the adjustment of the Springfield brakes?

A. The labor of fixing the brakes might occupy the fifteen minutes. I would tell a man what to do, and I would move somewhere else and see to something else, and before I got back again that would consume the fifteen minutes.

Cr.-int. 24. Then you mean you did not stay there ten or fifteen minutes directing the adjustment of the Springfield brakes?

A. I mean that I directed the work there the same as I did the whole business of the shop. It did not require my eye on it all the time to direct it.

Cr.-int. 25. So that your eye was not on it during ten or fifteen minutes on any day?

A. No, sir; it was not necessary.

Cr.-int. 26. Why was it not necessary?

A. Because it took perhaps two seconds to tell a man what to do, and it took him ten minutes to do it.

Cr.-int. 27. What was it that it would take you two seconds to tell a man to do, and take him ten minutes to do it?

A. To shorten up that rod; to shorten up another one; to loosen up another one. I would give the directions, and go and see that it was done.

Cr.-int. 28. While you were away, after you had given the directions, of course you do not know anything about what the men did, do you?

A. No further than I went to see what was done when I came back, and if it was not done properly I would tell them to alter it.

Cr.-int. 29. How many men were there in that car-house attending to the adjustment of the Springfield brake during this week to whom you gave any such directions as you have stated?

A. There were three men to whom I gave directions to see to those Springfield brakes. There was Copperthorn, Hillock, and McAllister.

Cr.-int. 30. Why was McAllister employed as one of those three men to do that work?

A. He was not employed, as a general thing. When the other men were engaged at other work I sent him.

2150 Cr.-int. 31. Haven't you just said that three men were employed during that week to adjust the Springfield brakes, of whom McAllister was one?

A. Yes, sir; but not all at one time.

Cr.-int. 32. How much time was each one of them employed?

A. Some days I would send only one man up there; he would do what was necessary, and come back again before the train went out; he might not be gone more than fifteen minutes. As a general thing, they occupied all the time that the train remained there; whether they had work to do or not, they would use up that amount of time before they came back to the shop.

Cr.-int. 33. What would they be doing to occupy the whole fifteen minutes, if there was no work to be done about the train?

A. Stand around and loaf, as workmen generally do when the eye of the superintendent is off of them.

Cr.-int. 34. How much time during this week was McAllister there, attending to those Springfield brakes?

A. He was there no definite time, only when he was sent.

Cr.-int. 35. That is evading the question. Please answer how much he was there, or how much he was sent; just which way you choose to look at it. If he was there when he was sent, he was there. How much time was he there? That is what I want to know.

A. I will put it at forty minutes. That is about the time the train remained in the house. He would stay as long as it was possible to have an excuse for staying.

Cr.-int. 36. How do you know what his motive for staying was?

A. He was a man who was termed a general loafer in the shop. That was his character in the shop—a general loafer. If you are going into his personal character, I can give it; but that I don't think has anything to do with the case.

Cr.-int. 37. Have you any personal knowledge that during that week McAllister remained in that car-house any longer than was necessary to attend to those cars? Answer only what you know personally.

2151 A. I couldn't say that, because it was not fixed upon my mind. It was done as the general routine of work.

Cr.-int. 38. How many days in that week was McAllister there forty minutes a day, attending to those Springfield brakes?

A. I will say six days, and let it go, forty minutes a day.

Cr.-int. 39. How many of those six days did you send any other man there during the forty minutes that the train was in the car-house, to attend to those Springfield brakes?

A. I can't say. I sent them when in my judgment I thought it required more than one man to do the work. There were so few minutes to do the work that if I thought one man couldn't do it I sent two, and then I would go myself to see that it was done.

Cr.-int. 40. What is your best recollection of the number of times you sent any other man besides McAllister to aid in adjusting those Springfield brakes?

A. I cannot answer that with any certainty.

Cr.-int. 41. Did you send another man once during that week?

A. Certainly once.

Cr.-int. 42. Did you send another man twice?

A. I could say twice, and might be every day. The object was to make these brakes work as well as they would.

Cr.-int. 43. Why did you want to make those brakes work as well as they would that week?

A. To get as good a record of them as we could. The brake was a poor brake, we knew, and we wanted to get as good a record of the operation of it as we could.

Cr.-int. 44. Did you know at the time what was going to be done with the record of it that you speak of, after that week's trial was over?

A. Not from any positive knowledge.

Cr.-int. 45. Before that week's trial commenced were you told by any person anything which led you to understand that it was of any importance that that brake should be made to work as well as it would during that week?

A. Not particularly on that week; I had no personal knowledge that the trial was to be made.

2152 Cr.-int. 46. Why was it, if you had no personal knowledge that the trial was to be made that week, were you so particular to see that the brake was made during that week to work as well as it could?

A. Well, the understanding was that the brake was to be taken off, and they wanted the brake to be put and kept in good order for a week, and run it, to get a good record of it. That was the reason I had, as far as I understood it.

Cr.-int. 47. What was the understanding which you had as to what use was to be made of this record after this week of trial was over?

A. Well, from any knowledge outside of my own impressions, I do not know anything about what use was to be made of it.

Cr.-int. 48. What were your impressions about it?

A. That it was to be used as evidence in this lawsuit.

Cr.-int. 49. Were your impressions about that brake such that you were led to exercise special care, as you have stated just now, to keep it in such order that it would work as well as it could during that week?

A. Yes, sir; that was the object.

Cr.-int. 50. You tried to accomplish that object, did you, during that week?

A. We tried to make it do as well as the brake was capable of doing.

Cr.-int. 51. So far as you know, did all of those men who took part in adjusting the brake during that week try as hard as they could to so adjust it as to make it work as well as it possibly could?

A. No further than men all try to do their work satisfactorily. They knew nothing about the cause of the special care to be used.

Cr.-int. 52. But they knew, didn't they, that there was something going on that week, whether they knew what it was or not?

A. They knew there was competition between that brake and another brake for superiority in working. They knew nothing about the lawsuit.

2153 Cr.-int. 53. But they knew, didn't they, that there was a special reason why that brake must be made to work as well as it could during that week?

A. Yes, sir; I gave them orders that it was necessary to keep the brake in as good order as we could, to make it operate suitably.

Cr.-int. 54. During that week?

A. During that week.

Cr.-int. 55. How long does it take you, ordinarily, to adjust the Hodge brakes on a car?

A. About ten minutes.

Cr.-int. 56. How many men do you ordinarily send out for the purpose of adjusting the brakes on one car?

A. I don't send out any to do it.

Cr. int. 57. Does itself, does it?

A. When the brakes are put on they are put on properly, and as the shoe wears they shorten the connecting-rod between the two bars; that is all it requires unless something breaks.

Cr.-int. 58. How many minutes does it take to shorten those connecting-rods on one car?

A. About five minutes, generally speaking. A man might work an hour to get off a bad-working nut.

Cr.-int. 59. My question was, of course, generally speaking, and you answer that, five minutes, do you?

A. Yes, sir.

Cr.-int. 60. How many men did you send to adjust the Hodge brake on one car?

A. None at all.

Cr.-int. 61. How did it get adjusted, then, if you sent nobody to do it?

A. When the brakes were put on they were put on properly, and as the shoes wore out the man in the car-house who looked over the cars tightened up the nut on the rod, as the shoes wore. That is all the adjusting they got.

Cr.-int. 62. How many of those men now referred to did it take to make this adjustment of one Hodge car?

A. It would take one man five minutes, if it needed adjusting.

Cr.-int. 63. How many cars do you say had the Springfield brake on upon the Lowell road during that trial week?

A. Four.

2154 Cr.-int. 64. Do you know anything about the working of that brake in its use out on the road during that trial week?

A. No more than hearsay. I went over the road once with it, and it made the stops then within a very few seconds of the time that the best working of the Hodge brake would make.

Cr.-int. 65. That is all you know about it?

A. I only went over the road with it once, for the purpose of seeing the operation of it.

Cr.-int. 66. With the Hodge brake, are you in the habit of going into the car-house to direct the men what to do to adjust it?

A. It don't require any adjusting, as I say; after it is once properly fixed it wears the shoes out, and when new shoes are put on, it requires the lengthening of the rod again. (Question repeated.) No, sir.

Cr.-int. 67. Was McAllister's trade that of a car-builder?

A. No; his trade, I think, is a millwright.

Cr.-int. 68. He was a mechanic by trade, was he?

A. An indifferent mechanic.

Cr.-int. 69. So far as you know, how long had he been engaged in working upon cars?

A. Not to exceed three years, to my personal knowledge.

Cr.-int. 70. Did that working upon car include putting brakes upon them, and seeing that the brakes were in order?

A. No, sir.

Cr.-int. 71. What did it include?

A. It included jacking up cars, taking out trucks, shifting wheels into the trucks, and renewing parts of the trucks.

Cr.-int. 72. Do you think a man who did that work for three years would not be able to tell when a brake was in order, and what needed to be done to it to keep it in order?

A. I don't think he could.

Cr.-int. 73. Why, then, did you send him to do this work of adjusting the Springfield brake during this week, if it was so important as you have stated that the work should be done just right?

A. I don't think I sent him many days to do it. When it was
2155 not convenient to send another man he was sent, but I did not
rely upon him to do it. M'r Copperthorn and Hillock were the two men that I relied upon to fix the brake. They put it on to the cars and they understood more about it.

Cr.-int. 74. It took at least two men to keep these Springfield brakes adjusted during that week?

A. No, sir; not necessarily.

Cr.-int. 75. If it did not necessarily take two men to keep them adjusted that week, why did you have three men employed during that week to do it?

A. I did not have three men at one time. Some days it would be one man, and some days it would be another man.

Cr.-int. 76. Haven't you stated that McAllister worked at the adjustment of that brake every day during that week, and that you had two other men in addition helping him?

A. Not positively. You have confounded my statements together. The three men were employed during that week to keep these brakes in order. Some days one man would go, and some days another would go, and some days two of them would go. Some days it included McAllister, and other days it did not. Therefore, I cannot say positively how many days McAllister was there, or how many days another man was there.

Cr.-int. 77. You cannot swear, can you, that McAllister was not there every one of the six days of that week?

A. No, sir; I say I can't swear there was one or the other of them there.

Cr.-int. 78. You cannot swear that at least one of the other two men was not there also every one of the six days of that week?

A. No, sir; I could not do that.

Cr.-int. 79. Can you swear that the third man was not there also every one of the six days of that week?

A. I could swear that the third man was not there. You know it is very difficult to get at a point, where you are superintending general work. The statements I make I can substantiate as far as I go. I don't want to go any further than I can substantiate.

Cr.-int. 80. Then you really think, do you, that McAllister did not know how to adjust a car-brake during that week?

2156 A. Not to my standard of knowledge.

Cr.-int. 81. Do you think he could have adjusted the Hodge brake during that week?

A. The Hodge brake does not require any adjusting.

Cr.-int. 82. Does the Hodge brake never require to have the nuts on the brake bars taken up?

A. Only when you put on new shoes.

Cr.-int. 83. Do you think that McAllister during that week would have been able to take up the nuts on the brake-bars of the Hodge brake?

A. Possibly he might, and possibly not. Sometimes he was in such a condition that he did not know whether he stood on his head or his feet. Not often so when he was sent to the car-house.

Cr.-int. 84. You think that during that week, when you thought it was very important to have that brake adjusted so that it would do its very best, you sent an intoxicated man to do the work?

A. I looked out and saw that he was not intoxicated, when I sent him there.

Cr.-int. 85. Then do you think that during those parts of the week when you looked out and saw that he was not intoxicated, and therefore sent him to do the work, that if he had been engaged in taking up the nuts of the Hodge brake, he could have done it?

A. Probably he could.

Cr.-int. 86. Have you not stated in your direct examination that it is no more to take up the nuts on the Springfield brake than it is on the Hodge brake?

A. It requires no more skill, after it is once adjusted properly.

Cr.-int. 87. Then you think if McAllister had not been intoxicated he could have taken up the nuts on the Springfield brakes that week?

A. Yes; if he tried to do it properly. I should think any man ought to do it after he is told what to do.

Cr.-int. 88. Then, on the whole, you think McAllister could have done the work of adjusting the Springfield brakes that week, if he was not intoxicated when he did it?

2157 A. If he did as he was told, I think he could have done it.

Cr.-int. 89. Have you not already stated that the men who worked at adjusting the Springfield brakes tried hard to obey your orders, and do as they were told?

A. Yes; I suppose they did.

Cr.-int. 90. Have you any reason to doubt that they did?

A. I have no personal knowledge that they did try.

Cr.-int. 91. That is not the question. Have you any reason to doubt that they tried to obey your orders?

A. No; I have no reason to doubt that they tried to obey orders.

Cr.-int. 92. You have already stated, have you not, that you did not send McAllister to do that work at any time during that week when he was intoxicated?

A. I could not swear to that. My impression is, that I would not send an intoxicated man to do any work in the car-house. (Question repeated.) Yes.

Cr.-int. 93. Then you think, don't you, that you did not send him when he was intoxicated; and, if he was not intoxicated, he could have done the work properly on those brakes; that, as the fact was, he did do the work properly?

A. If he did it as he was told to do it, he did it properly.

Cr.-int. 94. Have you any reason to doubt that he did do as he was told to do?

A. I have reason to doubt that he did it as he was told to.

Cr.-int. 95. What reason have you?

A. His own statements, under oath.

Cr.-int. 96. Mention his statements under oath which lead you to doubt it.

A. Why, in regard to one shoe being off an inch and a half, and the other half an inch; and his not knowing whether to turn one nut or another nut to regulate it.

Cr.-int. 97. Where has he said that he did not know whether he was to turn one nut or another to regulate it?

A. Perhaps he did not, in those precise words; but he said he did not know what to do, and he would send for me to come up and direct him.

Cr.-int. 98. If you directed him what to do, he would know what to do, would'nt he?

2158 A. Yes, sir; if he was in a suitable condition of mind to know anything.

Cr.-int. 99. You have already said, have you not, that you did not send him during that week when he was not in a suitable condition of mind?

A. Yes; that is the statement.

Cr.-int. 100. Have you any personal knowledge that the Springfield brake or brakes which McAllister during that week adjusted were not in the condition which he has testified they were?

A. I know he would fix them to the best of his ability, and they were not satisfactory, and he would send for me to come and regulate them. (Question repeated.) Yes; I know they were not in that condition, after they were adjusted. They might have been in that condition when they came into the house if the rods were broken.

Redirect:

Int. 41. You spoke of the Springfield brake being a poor brake. With what other brake did you compare it?

(Objected to.)

A. That was comparing it to the Hodge brake.

Int. 42. Then, if I understand you, as compared with the Hodge brake, the Springfield brake might be regarded in the light of a poor brake?

A. Yes, sir.

Int. 43. How would you regard it if there were no such brake as the Hodge brake in existence?

A. As far as my knowledge goes, it is equal to the other brakes in use.

Int. 44. How does it compare with the so-called Tanner brake?

A. Well, it is as good as that. There would be the same trouble with the Tanner brake as with the Springfield brake.

Int. 45. You will please look at "Defendants' Exhibit Nichols-Tanner brake," and state whether that is what you regard as the Tanner brake.

A. That is what we put on as the Tanner brake, with the exception of altering the leverage on that centre lever, giving it a little power.

2159 Int. 46. So far as your knowledge goes, in applying the Tanner brake, did you invariably connect the two rods at the end of the lever?

A. Not always. We set one rod in from seven to nine inches.

Int. 47. Is it usual to connect either way—either at the ends of the lever, or set it in?

A. We connected it both ways in the trial we made of it.

Int. 48. What is necessary in taking up the wear on the Tanner brake?

A. Take it up on the rods, the same as the other.

Int. 49. Must it be taken up uniformly, or does it not make any difference?

A. It must be taken up equally all around, to keep the length of the rods equal, the same as the Springfield brake, to have it operate.

Int. 50. How would the Hodge brake be affected, should you take up the wear on one truck and take none up on the other truck?

A. It would equalize itself, if there was room enough on the rod to wind up the slack.

Int. 51. Would the Tanner brake equalize itself under such a state of things?

A. No, sir.

Recross:

Cr.-int. 101. How much have you ever used the Tanner brake?

A. I have put it on twice. We had two spells of experimenting with it, the date I can't distinctly say; about, say, four years ago. The first trial it was put on and run a short time and then taken off; I can't state distinctly how long we used it, but a very short time; it did not exceed three weeks. Then we put it on and run it in competition with the Springfield brake last summer.

Cr.-int. 102. How long?

A. We ran it perhaps six weeks.

Cr.-int. 103. Those three weeks and six weeks are all you have ever seen of the Tanner brake?

A. All the use I have had of the Tanner brake.

2160 Cr.-int. 104. How many cars was it on at either of those periods?

A. One only at each period. It was first put on to one car and run in competition with this Springfield brake last summer, and the brakemen liked the Springfield brake best, as they recognized it—the brake with two chains—and we took the other one off, and altered it to the Springfield brake.

Cr.-int. 105. Do you know why the Tanner brake was put on at that time and run in competition with the Springfield brake?

A. No, sir.

Cr.-int. 106. Was anything said to you by anybody about it?

A. No further than to give me orders to put it on.

Cr.-int. 107. Did you know anything about this lawsuit at that time?

A. Yes, sir.

Cr.-int. 108. Do you know whether the brakemen knew about the lawsuit at that time?

A. I think they did not, by their questions to me.

Cr.-int. 109. Who were those brakemen?

A. Wing was one of them.

Cr.-int. 110. And Emerson the other?

A. Emerson, I think, was not on the train at that time.

Cr.-int. 111. Who was the other one?

A. I could not state his name.

Cr.-int. 112. How was the Tanner brake arranged at the time it was used on the Lowell road, in competition with the Springfield brake?

A. Arranged with the fixed lever in the centre; arranged like the model "Defendants' Exhibit Nichols-Tanner brake."

Cr.-int. 113. In all respects like that model?

A. Yes, sir. First we connected the rods in a straight line at the end of the lever; afterwards we carried one rod in nine inches, to give it a leverage on each side the two opposite rods.

Cr.-int. 114. How was the Tanner brake, at the time you say you saw it there about three weeks, about four years ago?

A. It was arranged in the same way as the model referred to, except that the rods were carried in seven or nine inches.

2161 Cr.-int. 115. Were the truck-levers on each of those occasions, four years ago and last summer, arranged as they are in "Defendants' Exhibit Nichols-Tanner brake"?

A. Yes; just the same.

Cr.-int. 116. You never saw the Tanner brake used as the regular brake on a railroad, did you?

A. No, sir.

Cr.-int. 117. You have no knowledge, then, about how it operates under such circumstances, have you?

A. No, sir.

Cr.-int. 118. Then, when you say in your redirect examination that you meant the Springfield brake was a poor brake as compared with the Hodge, or that it is equal to the other brakes in use, what other brakes in use did you refer to?

A. The Tanner and the Stevens; that is all I have any knowledge of.

Cr.-int. 119. Do you think the Springfield brake is as good a brake as the Stevens brake?

A. I have not had experience enough with the Stevens brake to form an opinion.

Cr.-int. 120. Why, then, did you say that you thought the Springfield brake was as good a brake as the Stevens, if you had had no experience with that?

A. Because they both answered the purpose of stopping the train.

Cr.-int. 121. Do you think the Springfield brake will answer as good a purpose in stopping a train as the Stevens brake?

A. Yes, sir.

Cr.-int. 122. You fell positive of this, do you?

A. Yes, sir.

Cr.-int. 123. Would you, as a master car-builder, be as willing to use the Springfield brake upon all the passenger cars of a railroad as the Stevens brake?

A. I don't know but what I would.

Cr.-int. 124. Can't you make your answer any more definite than that? Would you? That is the question.

A. No; not unless I had the experience to form a better opinion.

2162 Cr. int. 125. Why, then, if you have not had experience enough to form a better opinion, do you say that the Stevens brake is as good as the Springfield brake?

A. That is my impression, because they both answer the purpose of stopping trains.

Cr. int. 126. Do you know any difference between them in respect of stopping trains?

A. No, sir.

Cr. int. 127. If a brake upon a passenger train, when experienced brakemen do the best they can with it, lets a train run by stations, do you consider that to be as good a brake as a brake which, under the same circumstances, does not produce that effect?

A. No, sir; it is not as good a brake; is not in as good condition. It don't necessarily condemn a brake if the brakemen let the train go by a station. Sometimes the best brake does that.

Cr. int. 128. Suppose a brake in its regular use, kept in as good condition as is common upon first-class railroads, and in the hands of experienced brakemen, permits passenger trains to frequently run by stations, do you consider that as good a brake as a brake which does not do that?

A. If there was equal care used by the brakemen to stop the train in both cases, I should consider that the poorer brake of the two that let the train go by. Ordinarily, it all depends upon the brakemen whether a train runs by or not.

Cr. int. 129. Take the same brakemen, on the same train under the same circumstances, and doing in each case as well as they can, and the brakes being respectively in the condition in which they are ordinarily kept upon first-class railroads, on passenger trains, would you or not consider that a brake which frequently allowed such a train to run by stations to be as good as a brake which did not do that?

A. I cannot answer that positively, because there are so many provisos to it. It is owing to the skill of the brakemen. (Question repeated.) The brake that allowed the train to run by the stations would evidently be the inferior brake at that time; it would not follow it was an inferior brake at all times.

2163 Cr. int. 130. Suppose that, taking one month with another, a brake kept in as good order as brakes are usually kept upon first-class railroads, would let a passenger train run by stations, in the hands of experienced brakemen, who were operating the brake as well as they could, would you or not consider such a brake as good a one as another brake, on the same train, under the same circumstances precisely, which did not permit the train to run by?

A. I should think the brake that held the train at the stations was the best brake.

Cr. int. 131. Would you, as a practical railroad man, use a brake upon your road, which, under the circumstances named in the last question, would permit passenger trains to run by stations, if the choice was left with you?

A. Not if there was one that evidently held them at the stations. I would use the best brake.

Cr. int. 132. In your answers in this deposition to-day in reference to any comparison between the Springfield brake and the Tanner, have you had any other experience with the Tanner to go by than the experience you have referred to here as continuing over about three weeks, four years ago, and about six weeks last summer?

A. No, sir.

BENJ. C. READ.

Deposition of Edward Lang, recalled.

Int. 1. Are you the Edward Lang who testified for the complainant in this case, September 24, 1872?

A. I am.

Int. 2. Please look at "Defendants' Exhibit, Springfield brake No. 2," and state whether the brake thereon represented is the same as the brake applied to passenger cars No. 12 and No. 40, on the Boston and Providence R. R. and used thereon from February, 1872, to November of the same year.

A. Yes, sir.

Int. 3. Look at "Defendants' Exhibit, Nichols-Tanner brake,"
2164 and state whether the brake theron represented is the same as the one applied to car No. 10, on the Boston and Providence road, and used thereon for the time above stated.

A. Not exactly the same. I think the rod from the centre-lever to the truck-lever was put in ten inches from the outer end of the centre-lever.

Int. 4. Were the truck-levers arranged the same on said car No. 10 as seen in the model?

A. Yes, sir.

Int. 5. The size of windlass and size of shaft on which the chain winds the same?

A. The same; 16-inch wheel and inch and a half barrel.

Int. 6. How is the wear of the brake shoes taken up on both these exhibits?

A. By nuts going through the brake beam.

Int. 7. Is it necessary that there should be an accurate adjustment in both exhibits to get the best results?

A. Yes, sir.

Int. 8. Supposing you should take up the wear of the shoes on one truck and not on the other, in one or both of these exhibits, what would be the effect on the operation of the brake?

A. Well, it would brake harder on one truck than on the other.

Int. 9. Then, in that respect, what is true of the Springfield brake is also true of the Tanner brake?

A. Yes, sir; I should say so.

Int. 10. Was there or not any complaint made to you about the brakes on cars Nos. 10, 12, and 40, by any one before G. F. Lincoln and H. M. Rogers went to Springfield to testify in this case?

A. Not that I remember in particular.

Int. 11. What was the nature of that complaint if any, after their return?

A. Well, they did not like the brakes so well as they did their old ones.

Int. 12. What do you mean by "old ones"?

A. I mean the Hodge brake.

Int. 13. Why were not the brakes taken off from cars Nos. 10, 12, and 40, on the request of M'r Rogers?

2165 A. Because the superintendent gave no orders to have them taken off.

Int. 14. And you were therefore obliged to run them until such time as he did give the order?

A. Yes, sir.

Int. 15. About how long was it after they returned from Springfield that you received the order from the superintendent to remove the brakes from the aforesaid three cars?

A. Well it might have been as long as two months; it might not have been more than six weeks; I can't tell exactly.

Int. 16. Then, from the time the brakes were put on said three cars, in February to August, there was no special complaint came to you with regard to the working of the same, as I understand you?

A. No, sir.

Int. 17. And when the complaint did come to you, after the return of the aforesaid men from Springfield, it was for the purpose of getting on what they regarded as a better brake; the old Hodge brake?

(Objected to as leading.)

A. Yes, sir.

Int. 18. You will again look at "Defendant's Exhibit, Nichols-Tanner brake," and state at how early a time said brake was in use on cars of the Boston and Providence Railroad.

A. 1847.

Int. 19. What month in 1847?

A. I commenced work the 19th day of October for the Boston and Providence Railroad.

Int. 20. Is there any doubt in your mind as to the correctness of your answer, to wit: that said brake was in use on that road in October, 1847?

A. No, sir.

EDWARD LANG.

BOSTON, *April* 21.

Deposition of Benjamin Ray, recalled.

Int. 1. Were you examined in this case at Springfield, Mass., July 31, 1872?

A. Yes, sir.

2166 Int. 2. Please look at "Defendant's Exhibit, Springfield brake, No. 1," and state whether the brake thereon correctly represents the Springfield brake as applied to cars 123 and 124 of the Boston and Albany road?

A. I should say it did, exactly the same.

Int. 3. Marcus L. Braman, who was brakeman for a time on William Jennings' train, on which the Springfield brake No. 1 was used, has stated, in answer to the ninth direct interrogatory, which reads as follows: "How did those Springfield brakes work, as to holding the train?" "Worked very poorly." "Int. 10. State what difficulty you found with them while you braked on them?" "Ans. The most difficulty I found, I couldn't hold the train with them. They didn't work; didn't do the work." And in answer to the thirteenth direct interrogatory, he says: "You couldn't discover that there was any brake on the car at all; couldn't discover that it held the car a mite." Were you in the habit of making inquiries of said Braman in relation to the working of this brake? And if so, state what answers he made to you.

(Objected to as being incompetent for the purpose of contradicting Braman.)

A. I used to ask him when they came in, and he said they worked as well as he wanted any brake to work. That is just the answer he gave me.

(Answer objected to.)

Int. 4. Was there applied to car 123 of the Boston and Albany Railroad what is called the Tanner or centre-lever brake, and run in connection with the Springfield brake?

A. Yes, sir.

Int. 5. Please look at "Defendant's Exhibit, Nichols-Tanner brake," and state whether the brake thereon correctly represents the said Tanner brake, as applied to a car of the Boston and Albany road?

A. I should say it did represent it.

Int. 6. Please look at the centre lever on the body of the car, and state whether it was arranged on said car at the same angle that it is in the model.

A. I should say it was.

Int. 7. At what angle, as near as you can judge, was it arranged?

A. They usually put them at an angle of forty-five degrees.

2167 Int. 8. Then it was not set at about a right angle to the body of the car?

A. No, sir; not on the car that I saw—123.

Int. 9. In answer to the twenty-first interrogatory, which is as follows: "Have you any knowledge of an accident happening in shifting those cars with the Springfield brakes on them? If so, please state what you know about it." Said Braman replied, "Yes, sir; I was running on the train, and was taken sick in the morning. I came in at night; I had a brother running on the Newton Lower Falls train; when we came in at night I asked M'r Hobart, the depot-master; told him I was sick, and asked him to let my brother do my switching. So he did, and I went home. The first thing I heard in the morning was that the bunter-post in the depot was all smashed off, and the rear platform of the rear car, and the platform of the second car." "Int. 22. Do you recollect the number of that car?" "Ans. No, sir; it was 123 or 124; I don't know which car was behind." "Int. 23. How badly smashed were the platforms of either of these cars?" "Ans. The rear platform of the rear car—the bed pieces were broken off. That was the car that struck the post, and the rear platform of the second car was injured. It wasn't smashed off entirely, but it was so that it had to be sent to the shop to be repaired." Do you know anything about this smashing platforms in cars 123 and 124?

A. No, sir.

Int. 10. Were you there so that you might know if anything of that character took place?

(Objected to.)

A. I can't tell exactly whether I was there that day or not; but I think likely I was.

Int. 11. If anything of that kind had happened to cars 123 and 124, would you have known it?

(Objected to.)

A. I should have been very apt to.

Int. 12. Have you any doubt that you should have known it?

(Objected to.)

A. No doubt whatever.

Int. 13. Interrogatory 27 put to said Braman is as follows: "How

well, if at all, were you able to take up the slack of the train
2168 when the Springfield-brake car was the rear car of the train?" Ans. "It was impossible to do it." Have you had any experience with the Springfield brake that would corroborate this statement?

(Objected to.)

A. None at all.

Int. 14. What has been your experience in reference to that brake?

(Objected to as leading.)

A. I have taken it up, and used it just the same as other brakes on the road. I never found any difficulty with it.

Cross-examination by M'r Cozzens:

Cr.-int. 1. Is it just as good as the Hodge brake?

A. It is to me. I do not apply it, sir.

Redirect:

Int. 15. About how often have you renewed the shoes on car 123 having the Springfield brake thereon, since the brake was put on in December, 1872?

A. I can't say exactly how often.

Int. 16. Well, about how often?

A. I should say three, four, or five times. They were renewed about a fortnight ago.

Int. 17. Did I understand you that the shoes require renewal about once in five or six weeks?

(Objected to as leading.)

A. It depends altogether upon where the cars run.

Int. 18. I mean one run regularly between Boston and Albany, going out one day, and back the next?

A. They require renewing about once in six weeks on that train.

Int. 19. And have they, according to your best judgment, been so renewed since December, 1872?

(Objected to.)

A. I should say so. I can't say for a certainty.

Recross:

Cr.-int. 2. How may cars on the Boston and Albany Railroad now have the Springfield brake on them?

A. There are four, I think.

Cr.-int. 3. How many had it on at the time you gave your testimony in this case, July 31, 1872?

2169 A. Five.

Cr.-int. 4. Do you know of the sending out of Jennings' train last Thursday from Boston to Albany at the time when brakemen O'Brien and Gardner, and also M'r Waterman were sent on it.

A. Yes, sir.

Cr.-int. 5. The Springfield brake was in four cars of that train, on that day, was it not?

A. Yes, sir.

Cr.-int. 6. Were the Springfield brakes on those four cars on that day in a bad state of adjustment?

A. I should say not.

Cr.-int. 7 Was the adjustment good and perfect, in your judgment?

A. Yes, sir; about the same as they have been running.

Cr.-int. 8. What, if you know, was the design when that train was sent out? Was it to go to Albany and return with those brakemen, and M'r Waterman on it?

A. I knew they were going out; I didn't know anything about their return. I knew they were going to Albany.

Cr.-int. 9. Did you see them when they came back?

A. No, sir. The first I saw of them was in the office of M'r Yerrington, in Pemberton Square.

Cr.-int. 10. When did you expect them back?

A. I expected them back on the same train the next day—I did.

Cr.-int. 11. Did you examine the adjustment of the Springfield brakes on that train that morning?

A. No, sir. The train goes out at five o'clock. I wasn't there.

Cr.-int. 12. When were the cars composing that train backed down into the depot ready to go out at five o'clock that morning?

A. They switch out of the house on to the starting track in the morning.

Cr.-int. 13. When was the train made up for that morning?

A. The cars were arranged in the way in which they were to
2170 go out, the afternoon before, and about twenty minutes before
five o'clock that morning, they were run from the house where
they had lain all night, down on to the starting track to go out.

Redirect:

Int. 20. Was the train made up any differently that morning from any other morning?

A. It was left the same as it generally is when I left the depot. I don't know how it was made up or put on the starting track, for I wasn't there.

Int. 21. How much of the time the afternoon before you went home at night, was that train in the depot or in the house at Boston?

A. I went home at six o'clock, and it was there from about 3:30 up to that time.

Int. 22. Did you, during any part of this time, look to see how the brakes were adjusted?

A. Yes, sir; I always do on every train.

BENJAMIN RAY.

Deposition of James A. Clark.

Int. 1. What is your name, age, residence, and occupation?

A. My name is James A. Clark; age, forty-three; residence, Boston; occupation, car-builder.

Int. 2. How are you now occupied?

A. I am inspector of cars on the Boston and Albany Railroad at the Boston and Albany depot in Boston.

Int. 3. How long have you been inspector of cars at the Boston and Albany depot?

A. I have been up to the depot there about three years come this November, I think, but I have been on freight, more or less, three or four years.

Int. 4. How long have you been inspector of passenger cars?

A. About three years.

Int. 5. Does looking after and repairing brakes, adjusting, etc., of the same, come under your department?

A. Yes, sir.

2171 Int. 6. Do you know anything about a number of cars being
equipped with what is called the Springfield brake?

A. Yes, sir.

Int. 7. How many cars were equipped with that brake and run in Jennings' train?

A. Five.

Int. 8. When was the brake taken off from one of those five cars, and under what circumstances was it taken off?

A. No. 124 broke down and run over a broken rail last winter; broke the truck and brake, and they put the Miller platform on to it.

Int. 9. And at the same time what brake did they put on?

A. The Hodge brake.

Int. 10. And took off the Springfield brake?

A. Yes, sir.

Int. 11. How many cars are now used in Jennings' train with the Springfield brake on them?

A. Four, I think.

Int. 12. How long has that train been running with the Springfield brake, should you judge?

A. A year and more, I should think.

Int. 13. Do you know Marcus L. Braman, who was formerly brakeman on Jennings' train?

A. I used to see him come in there on it.

Int. 14. What, if anything, did you ever hear him say in relation to the operation of the Springfield brake?

(Objected to.)

A. He said it was as good a brake as he wanted. He didn't want any better brake than that.

JAMES A. CLARK.

Deposition of Emery Stebbins, recalled.

Int. 1. Are you the Emery Stebbins who was examined in this case in the year 1872?

A. I am; I was examined in Springfield.

Int. 2. Please look at "Defendants' Exhibit, Springfield brake No. 3," and state whether the brake thereon is a correct representation of the one applied to the cars on the New York and Boston express line about the year 1856, and run thereon sixteen months, as testified by you in your examination aforesaid in 1872? 2172

A. It is the same thing.

Int. 3. Was the brake so represented on said exhibit applied by you to the New York and Boston express line cars about the year 1856?

A. It was.

Int. 4. Did you furnish the drawings from which the brake on said exhibit was made?

A. I did. I furnished M'r Whipple with drawings, and the model is like those drawings.

Int. 5. On cross-examination, at the time aforesaid, you testified that "the bottom end of the truck-lever set in a slot on the connecting rod, with a pin through it, so as to hold it permanently in its place, instead of being attached to the brake bar." Is the brake so described correctly represented in said "Exhibit, Springfield brake No. 3?"

A. It is.

Int. 6. In your direct examination at the time aforesaid you say, "All the difference between the brake exhibited in the model" (referring to the model described in that deposition as "Model A. E. Merwin, U. S. C."), "and the brake which was applied to those twenty-two or twenty-four cars, was that, in the brakes of these cars, but one chain wound round the windlass, and that chain was attached to the upper end of the lever in the first truck, and a rod attached to the same point connected it to the upper end of the lever in the second truck, and the same may be said of the attachment at the other end of the car. The reason why we put it on in this way was to get rid of the second chain, and save us the trouble of altering the windlasses." Is the same alteration seen in the model, "Defendants' Exhibit, Springfield brake No. 3," as is described in the language just quoted?

A. It is.

Int. 7. What kind of curves did the cars with said Springfield brake, marked "No. 3," have to pass over in the city of New York, to get into the station in New York City?

A. I can't tell the radius, but it is a very short curve. I did know the radius, too, once.

2173 Int. 8. Were you in New York at any time when the cars were run into that city with Springfield brake No. 3 on?

A. I was. I was only there temporarily.

Int. 9. At that time, did the cars run down to Canal street?

A. They didn't at that time.

Int. 10. Where did they run to?

A. They stopped at Twenty-seventh street.

Int. 11. How did the sharpness of the curves over which these cars were hauled with said brake affect the connections of said brake?

A. Well, they had to be connected very loosely to go round those curves and get into the yard.

Int. 12. How were the cars drawn round those curves?

A. By horses.

Int. 13. What would be the consequence were the brakes not adjusted very loosely in passing those curves?

A. It would stop the cars on the curves. They would not be very apt to leave the track, because the brakes would hug right on to the wheels.

Int. 14. How did this looseness of the brake, in order to pass said curves, affect its operations when upon the main track?

A. Made it very loose.

Int. 15. How did this looseness affect the operation of the brake?

A. It affected it in not holding the cars so well on account of its being so loose.

Int. 16. Were you in the habit of taking up the slack of the brake at Springfield?

A. We were when it was first put on, but we found that it made trouble for the New York folks in going round these curves in New York to get into the yard, and then we left them, as they adjusted them at the New York end of the road, which was quite loose, as seen in the exhibit.

Int. 17. And that adjustment was to allow them to pass those sharp curves without binding the wheels so as to stop the car on the curves?

A. Yes, sir.

2174 Int. 18. You will now please look at "Defendants' Exhibit, Hodge brake," and state whether the brake thereon correctly represents the same as applied to the said New York and Boston line of cars?

A. It does.

Int. 19. Did they, as represented, have a worm in each windlass-shaft?

A. Not every one of them. Part of them had them on, and some of them didn't.

Int. 20. Did they have a stop just back of the chain for the purpose of holding the rod and making a good brake at the opposite end, in the event the chain broke at the other end?

A. Yes, sir; all of them had the stop.

Int. 21. Did it also perform the office of relieving one end from the slack of the chain at the other end?

A. It did.

Int. 22. You were located at Springfield, Mass., as car-inspector of the Western Railroad at the time this change from the Hodge brake to the Springfield brake was made?

A. Yes, sir; I was located there, and put the brakes all on.

Cross-examined by M'r Cozzens:

Cr.-int. 1. State whether the Hodge brakes on this line of cars had the links holding up the cross-levers, so arranged as to run on slides, as shown in "Defendants' Exhibit," or was the top part of some of those links hinged to the car body, so as to swing instead of sliding?

A. Most of them swung, but there were a few of them that run on slides, like the "Exhibit."

EMERY STEBBINS.

Deposition of Benjamin W. Hobart.

Int. 1. What is your name, age, residence, and occupation?

A. Benjamin W. Hobart; I reside at the United States Hotel, 2175 Boston; am station-agent of the Boston and Albany road; I ran as conductor eighteen years, and have been in the station some six or eight years.

Int. 2. On what train did you run as conductor?

A. I ran the New York train between Boston and Springfield.

Int. 3. What is called the New York and Boston express line?

A. Yes, sir.

Int. 4. Do you recollect, during the time that you ran said train as conductor, of there being on said cars what is called the old Springfield brake?

A. Yes, sir.

Int. 5. Are you aware what kind of curves it had to run over to get into the station at New York, at Twenty-seventh street?

A. I have been over those curves, but I have no means of knowing the radius. I did not go through to New York. I ran from Boston to Springfield. It is just like going round the corner of one street into another.

Int. 6. How did the said Springfield brakes work when leaving Boston for Springfield, compared with when they came back from New York, and from Springfield to Boston?

A. The brakes always worked better out of Boston than they did coming to Boston.

Int. 7. How do you account for this difference?

A. I account for it by what the men on the train say. (Objected to.) I understand that the difficulty was from being obliged to let out the chain in order to go round those curves; let out the connections.

(Answer objected to.)

Int. 8. You are aware of the fact, are you, that the brake worked better as a general thing going from Boston, than it did when the train returned to Boston?

A. Yes, sir.

Int. 9. For the reasons you have stated?

A. That was always the explanation by the inspectors at Springfield. I get it from them.

(Same objection.)

Int. 10. Are you acquainted with Marcus L. Braman, who was formerly brakeman on the Boston and Albany road?

A. Yes, sir.

2176 Int. 11. How long has he been out of the employ of the company?

A. I should say a year.

Int. 12. Why did he leave the employ of the company?

A. That is pretty direct, but I suppose you want the fact. I discharged him for drunkenness.

Int. 13. Has there been used of late on the cars of the Boston and Albany road what is called the Springfield brake? If so, on what train?

A. No train except this that leaves Boston at five o'clock in the morning, and returns at half-past three—Jennings' train.

Int. 14. Has any complaint come to you in regard to the brakes on said train?

A. Well, I can't say that there has not been any complaint, because it would be very singular if any brake should run without any complaint. I think there has been no general complaint.

Int. 15. Have any accidents happened to that train within the last year?

A. None that I am aware of.

Int. 16. Do you consider the brake as used on Jennings' train, known as the Springfield brake, a safe brake to run on that road?

A. Well, the question of safety applied in what way?

Int. 17. As a general thing?

A. If adjusted, I consider it a good brake.

Cross-examined by M'r Cozzens:

Cr.-int. 1. You mean if carefully adjusted?

A. If the brake is properly adjusted.

Redirect:

Int. 18. And the wear of the shoes kept up?

A. Yes, sir.

Recross:

Cr.-int. 2. Do you consider the Springfield brake as good a brake as the Hodge brake?

A. No, sir, I don't.

2177 Cr.-int. 3. If you were the manager of a railroad, with such experience as you have had with the Springfield brake and the Hodge brake, would you use the Springfield brake on your cars, if you could get the Hodge brake?

A. I would not. I would give the Hodge brake the preference over any hand brake I ever saw.

Cr.-int. 4. Do you know of the sending out of Jennings' train last Thursday with the brakemen, O'Brien and Gardner, in connection with M'r Waterman?

A. Yes, sir. They went out on that train on Thursday, and went through to Albany.

Cr.-int. 5. Was the intention to run that train to Albany and back with those parties on it?

A. To run to Albany, but not back. The men only went to Albany, and returned by the next train. The regular men managed the train the next day.

Cr.-int. 6. I don't ask whether they did come back. I ask whether it was the intention to have them come back on the same train?

A. No, sir, it was not.

Cr.-int. 7. When did you expect those men back?

A. I expected them to come back that night or the next morning, as they saw fit, as passengers, because it was a hard day's work for the men to go from here to Albany, and brake at all the stations. I looked for them to come back at their own convenience, because I didn't expect them to do any work the next day. One came back that night, I think. It was not expected that they would make the round trip. I gave the order, and it was merely to go to Albany, and return at their convenience, or as soon as they could.

Cr.-int. 8. Are O'Brien and Gardner good brakemen?

A. Yes, they are considered such.

Cr.-int. 9. Is O'Brien still employed as a brakeman on the Boston and Albany road?

A. Yes, sir. M'r Gardner left of his own accord.

BENJAMIN W. HOBART.

(Indorsement on cover:) No. 306. The Chicago and Northwestern Railway Company, appellant, vs. Thomas Sayles. N. Illinois C. C. U. S. Filed 8th November, 1875.

[illegible] N. H. Sm

No 46 [illegible]

Oct. 9. 187

United States Supreme Court.

CHICAGO AND NORTHWESTERN RAILWAY
COMPANY, *Appellant,*

vs.

THOMAS SAYLES, *Appellee.*

ARGUMENT FOR APPELLANT.

BY GEORGE PAYSON.

CHICAGO:
[illegible] [illegible] Company, 112 [illegible] [illegible].
187

SUPREME COURT OF THE UNITED STATES.

CHICAGO AND NORTHWESTERN RAILWAY COMPANY, *Appellant*,
v.
THOMAS SAYLES, *Appellee*.
No. 306.

STATEMENT OF THE CASE.

This is a suit on a patent on car brakes, issued July 6, 1852, to Henry Tanner, assignee of Batchelder and Thompson, and assigned by Tanner to plaintiff. The original application, filed June 26, 1847, was for a "train" or "bumper" brake, operated by the cars crowding on each other, when the train slackens its speed. It was a crude and clumsy contrivance, and was never used, according to plaintiff's evidence in a single instance, and only once or twice according to defendant's, when it failed and was abandoned. Nearly five years after, the invention was assigned to *Tanner;* new and different specifications, drawings and model were filed, describing a brake of a very different and improved construction; not, as we believe, the invention of *Batchelder & Thompson*, but interpolated into the case by the said *Tanner;* the same brake having been invented and brought into public use at least as early as the spring of 1848, by one *Willard I. Nicholls*, and the brake used by appellant having been invented and patented by *F. A. Stevens* in 1851. The brake thus patented to *Tanner* was not a "train" brake, but a hand brake; it proved successful, and has been used on some of our roads, under the name of the "Tanner brake" from that day to this. The brake generally in use prior to 1850 was the old single brake, so called because it applied the brakes only to a single truck; though in fact a double brake, since it operated on all four wheels at once. This brake is still in use on freight cars, a few roads only having adopted the double brake on that class, as well as on their passenger cars. The improvement in this Tanner brake consisted in connecting the two single brakes, that is, the brake on each truck, with each other, and with the windlasses *by means of a centre lever*, so that all the brakes could be applied at once from either end of the car.

Other double brakes had been invented and used prior to the alleged invention of the *Tanner*, one of which still continues in use; but all these were held either not the same as the *Tanner*, or else abandoned experiments.

The double brakes now and for the past twenty years in use on most of our roads are the *Hodge* and the *Stevens*, the former patented in 1849, the latter in 1851. Both are claimed to be infringements, but this we wholly deny. The *Stevens* brake is the only one now before the court.

This suit was begun in 1861; the defendants denied the validity of the patent, and also denied infringement; both of which issues having been decided against them, the case was referred to the master, who found the saving to defendant in brakemen and wheels, by the use of this invention for five years, on only a small part of its road to be $63,638.40. Defendant's exceptions were overruled, and a decree entered for that amount. A petition was filed to open the decree on the ground of newly-discovered evidence; and on the argument a number of other points were presented by defendant. None of them, however, was sustained, but it having been shown that the damages decreed gave a value to the patent of at least sixty millions of dollars, the court, without assigning any other reason for it than that the damages were too great, struck off some $16,000.00 and entered its decree for $47,725, from which the defendant appealed.

The case is one of the most important that ever came before this court. If this decree is correct there is hardly a road that has not infringed this Patent. Its value as fixed even by this last decree cannot be less than Forty Millions of Dollars. A large number of other suits all over the country, now pending or soon to be brought, are awaiting the issue of this. Most of the defendants in these suits have never used anything but the *Hodge* or *Stevens* brakes. They have bought and paid for them on the belief that they were independent inventions, and no infringement. Yet they are now called upon to pay for the *Tanner* in addition, and to pay a sum so large, according to this decree, as to leave most of them no refuge but in bankruptcy.

QUESTIONS IN THE CASE.

1. Is not the patent void for errors affecting the application?
2. Is it not void for want of novelty?
3. Is the Stevens Brake an infringement?
4. Is not the estimate of savings excessive?
5. Was the correct rule adopted?
6. If so, was it correctly applied?

ASSIGNMENT OF ERRORS.

First. The court erred in not finding the patent invalid; for

The delay in prosecuting the application—The change made in the amended application—The delay in making this amendment—The doubt as to who was the author of it—The peculiar circumstances attending it. Or all of these causes taken together.

Second. In finding that Batchelder & Thompson were the inventors of the Tanner brake.

Third. In not finding the patent void for novelty, in view of

The Millholland Brake;
The Nicholls Brake;
The Stanley-Talson Brake.
The Camden and Amboy Brake.

Fifth. In its construction of the Patent.

Sixth. In finding that the *Stevens* Brake was an infringement.

Seventh. In directing the master to assess damages in addition to profits.

Eighth. In finding any saving of brakemen.

Ninth. In finding that defendant saved as many brakemen as it employed.

Tenth. In finding any saving of wheels.

Eleventh. In first assessing the saving of *brakemen* on the theory that twice as many must have been used with the single brake as with the double; and then assessing the saving of *wheels* on the theory that the same number of brakemen were used with both.

Twelfth. In charging defendants with an additional number of brakemen equal to those they employed; and then refusing to give them the benefit of that increased number, in estimating the saving of wheels.

Thirteenth. In assuming that whatever was saved by the double brake was the same as so much profit to defendant.

Fourteenth. In overruling defendant's exceptions to the master's report, severally and collectively; as follows:

1. For that the said master decided and in and by his said report stated that the brake known as the "Springfield Brake" was an unsuccessful and abandoned experiment and not a perfect practical invention, in disregard of the testimony of the witnesses William Jennings, Wilson Eddy, Henry W. Snow, John Mulligan and John B. Adams, as to the successful working of said "Springfield

Brake" long prior to the alleged invention of Batchelder and Thompson, and which testimony was before said master on said reference.

2. For that the said master, as appears by his report aforesaid, computed the amount saved to the defendant by the use of the Batchelder and Thompson invention over the use of the single brake, rejecting as a standard of comparison what is known in this cause as the "Springfield Brake," thereby wholly disregarding and refusing to consider the testimony of the witnesses before named in the first exception, and also the testimony of the witnesses Benjamin W. Hobart, James A. Clark, Benjamin Ray, Edward Lang, Benjamin C. Read, Henry Waterman, William O'Brien, George H. Gardner, Alfred Berney, John A. Hearn, V. D. Perry, S. L. F. Deyo, Only L. Smith, Henry F. Sampson, William McCormick, Henry A. Wright, Robert Hitchcock, Alpheus Wing, John D. Emerson, John C. Blood, H. M. Rogers, G. F. Lincoln, John Lightner, James Lyon, Charles Haradon, Henry F. Taylor, John Bartlett, William W. Stevens, Charles W. Marsh, John B. Adams, R. C. Steele, Cornelius Teeling, Lewis A. Shorts, Luther D. Hodgkins, John A. Smith, John W. Clark, F. D. Adams and William H. Russell, introduced before said master in said reference by the said defendant, showing the successful working of said "Springfield Brake" as a double brake.

3. For that the said master, as appears by his report in estimating the gains, profits, savings, benefits and advantages, accruing to the defendant by the use of the Batchelder and Thompson invention, as set forth in the Letters Patent to Harry Tanner, wholly disregarded the advantages of the double-acting brake known as the "Springfield Brake," over the single brake, as testified to by the defendant's witnesses above named in the first and second exceptions, and made comparison of the said Tanner brake directly with the single brake; whereas under the testimony aforesaid the comparison should have been made by him between the Tanner brake and the said "Springfield Brake."

4. For that the said master has assumed, and in and by his said report decided that, with single brakes, the defendant would have been compelled to employ double the number of brakemen and baggagemen in the management of its trains, that it did employ with the double brakes.

5. For that the said master in the making up of the account between the complainant and the defendant, assumed that by the use of the invention of Batchelder and Thompson, the defendant made a saving of the wages of one half the number of brakemen upon its passenger trains, when the fact is, as shown by said report that the defendant during all the term covered by said account, used the Stevens brake upon all its passenger cars.

6. For that the said master in the making and stating of the account between the said complainant and the said defendant, has allowed to the said complainant all the gains, savings, and benefits accruing to the defendant from the use of the best form of double acting brake, and has not in any manner made allowance or deduction therefrom on account of the defects and want of adjustability of the Tanner brake.

7. For that the said master in estimating the gains, profits, benefits, and advantages derived by the said defendant from the use of double brakes, has not allowed for any difference between that form of double brake known as the Stevens brake, which, as appears by said report, was exclusively used by the said defendant during the time covered by said report, and that form of double brake claimed to have been invented by Batchelder and Thompson, and described in the Letters Patent to Henry Tanner.

8. For that the said master has found, and in and by his said report decided that by the use of the alleged invention of Batchelder and Thompson, in

the Stevens brake there was a saving to the defendant of two sets of car wheels to each car per year.

9. For that the said master has found, and in and by his said report decided, that the Batchelder and Thompson invention embodied in the Stevens brake used by the said defendant, resulted in saving to the said defendant two sets of car wheels per car per year, during the entire time covered by said account, comparing said brake directly with the single brake, in order to reach that result, and making no allowance for the imperfections of the said Batchelder and Thompson invention when tested by itself.

10. For that the said master has assumed contrary to the facts as shown by the complainant's own witnesses, and in and by his said report has in substance decided that the use of the Batchelder and Thompson invention prevents the injury of car wheels by "spotting," and that this cannot be prevented by the use of the single brake.

11. For that the said master, in and by his said report, has calculated as the gains, savings, advantages and benefits accruing to the defendant from the use of the alleged invention of Batchelder and Thompson, not only the savings in the wages of brakemen, but also the savings in car wheels, the effect of which is a partial duplication of the actual gains and savings resulting from the use of a double-acting brake.

12. For that the said master, in the making and stating of the account, between the said complainant and the said defendant has not based the same upon the actual gains and savings resulting to the defendant from the use of the invention of Batchelder and Thompson, nor upon the testimony before said master as to the use of said invention by said defendant, but instead thereof has estimated said gains and savings according to vague and indefinite impressions of certain witnesses who testified in respect to the supposed savings in car wheels resulting to other railroad companies from the use of double-acting brakes on their cars.

13. For that the said master in the said report wholly disregarded the brake called the "Tender Brake" proved by the testimony of Wilson Eddy and others to have been in use continuously since 1843 and long prior to the alleged invention of the Tanner brake, and excluded the same in his comparison of the Tanner brake with prior devices and made his comparison of said Tanner brake directly with the single brake.

ARGUMENT.

(The references are to the top paging of the record. Figs. 1, 2, etc., refer to the figures in the chart at the front of this brief.)

I.

THE PATENT WAS VOID BY REASON OF THE ERRORS AND FRAUDS IN THE APPLICATION.

There are here several points distinct, yet working together.

1. By their *delay in prosecuting their application* the appellants forfeited their right to a patent. They filed their application June 26, 1847. It was wretchedly defective; the specification was most of it written on the face of the drawings; the description very imperfect, and the claim, "*The application to car brakes, to prevent collisions, &c., &c.*" p. 137.

December 9, 1847, they wrote to the Patent Office to stay proceedings, as they wished to make some further improvements; when, of course, the office did as requested. p. 138.

After this it may be supposed that they busied themselves in making the proposed improvement; they did nothing of the kind, however, according to the statement of Batchelder, p. 94; but having in about a month found out that they *wanted no improvement*, they then stood still till October 4, 1850, when *Heath*, their assignee, wrote to have the papers returned (for what reason does not appear) to *R. H. Eddy*, his attorney and an experienced patent solicitor, who, after keeping them idle in his hands for nine full months longer, returned them to the office, in the same imperfect shape in which he received them, without any change or amendment whatever. p. 139.

Just two months later, September 10, 1851, *Eddy* wrote to the office asking an examination; and thereupon, October 17, or little more than a month, the papers were examined and "returned for *entire insufficiency*," the correctness of which ruling has never been questioned.

Then comes another delay of six months on the part of the applicants, when on the 13th of April, 1851, *Eddy* returned the papers to the Patent Office with amendments, the character of which will be fully shown hereafter.

April 30, only 17 days after the office received the papers, they were again sent back, there being an entire discrepancy between the model and drawings, which could only be removed by the substitution of either new drawings or a new model. A new model was accordingly got up by *Tanner*, who had now become sole owner of the invention; and finally, July 6, 1852, *more than five years after the original application*, the patent was issued in its present shape.

They excuse this delay on various grounds, their own inexperience; the neglect of their agent; the neglect and crowded state of the Patent Office; and in support of this last, one *Cooper*, the Examiner in charge, is made to swear that the office was then a year behind hand, and that no new application could be examined for at least a twelve month.

As to the inexperience, we deny that it is any excuse. A party who pleads his own case, finds no favor on that account; but on the contrary is very apt to be turned out of court with a proverb anything but complimentary sent after him by way of reminder. The neglect of their agent is the same as their own. Moreover, their agent, *Heath*, was himself a principal, having become sole owner of the invention by assignment, April 17, 1847, before the filing of the application. p. 93; 138.

As to the crowded state of the Patent Office, *Cooper's* statement even if true, would only account for one year; and here is a delay of five. Neither will this excuse the delay of *Eddy* in keeping the papers nine whole months, and then sending them back in the same defective shape in which they were first prepared; nor the subsequent delay of six months in making the amendments. Nor did this press in the Patent Office prevent other more diligent inventors from obtaining their patents, and in the same department. *Stevens* obtained his patent in 1851, *Hodge* in 1849, *Turner* in 1848. There is no need, however, of arguing this point, for it is evident that the delay was due to none of these causes, but to the letter of applicants, in which they expressly instructed the Office to stay proceedings. It is true they allege that they afterwards wrote several times in relation to the examination, but received no reply.

But, if they wrote so many letters, why are none of them on file in the Patent Office? And when they did write in October, 1850, why was nothing then said as to their prior unanswered letters, or any neglect on the part of the Office? And if they did write those letters, how do we know what they contained, or that they required any answer? *Eddy's* letter of Sept. 10, 1851, gives us no light on either of these points. Nor is that letter any evidence even that any prior letters had been written. It is simply an unsworn statement of *Eddy* as to another unsworn statement of applicants.

The fact is, as we shall show, that the brake really invented by *Batchelder and Thompson* was worthless, and that they knew it; it was no more than natural, therefore, that they and those with them should press their application in the intermittent, half-hearted manner just shown.

Then how does this delay affect the patent? The authorities all assume that there *is* a delay which shall be fatal. Thus in *Adams v. Jones*, 1 Fish 529, it was held that the applicant, having by his application given notice of his intention, ought not to lose his rights by *mistakes in the Patent Office*, or delays in courts, *unless gross laches be imputed to him.* But that one might justly be treated as having abandoned his application if not prosecuted with reasonable diligence.

So in *Rich v. Lippincott*, 2 Fish. 9; *Dental Vulcanite Co. v. Weatherbee* 3 Ib. 87; *Blandy v. Griffith*, Ib. 609; *McMillen v. Barclay*, 5 Ib. 189; *Johnson v. Fassman*, Ib. 471; *Goodyear Dental Vul. Co. v. Smith*, Ib. 588; *Roberts v. Ryer*, 6 Ib. 309; *Jones v. Sewall*, Ib. 365; *Howe v. Williams*, 2 Cliff. 262; *Smith v. Goodyear Dent. Vul. Co.*, 3 Otto, 486.

All these cases decide by necessary implication that the delay would have been fatal if it had been in the power of the applicants to prevent it. As to the time lost by the delay, it was held in *Blandy v. Griffith* that a delay of *only eleven months*, was under the circumstances "*not unreasonable.*" There an erroneous rejection on appeal had been made; but no one pretends that there was anything of the sort in this case.

In *Clark v. Scott*, Off. Gaz. II, p. 7, defendant claimed that the patentee's neglect to prosecute his claim after rejection, for two years and eight months, was an abandonment. Held by *Blatchford*, J., clearly agreeing with that view of the case, that defendants could not avail themselves of it, because not set up in their answer. The answer in this case does contain that allegation.

Where one suffered his claim to remain as a rejected application more than five years, held to have forfeited his right to a patent. *Raymond, ex parte Merrick*, J., 1861. See also *Ellithorpe v. Robertson; Justice v. Jones; Spear v. Stuart; Savory v. Louth; Marcy v. Trotter; Berg v. Thistle; Sturtevant v. Greenough; Loveridge v. Dutcher*, and *Snowden v. Pierce;* Law's Dig., 146–148.

So in *Bourcicault v. Hart*, 8 Chi. Legal News, 258, it was held that an author must publish his book in a *reasonable time* after filing the title page; and the same rule is there said to apply to patents. "The inventor must put his claim into the form of a well defined specification, and so place it upon record that he *cannot alter it to suit circumstances*, and so that other inventors may know precisely what it is that has been invented." "It was never heard, however, that he could conceal the particulars of his invention, and by filing a general statement of an improvement, cut off the rights and claims of others." The delay there was only about six months.

The Act of Congress of 1870, Sec. 32, fixes two years as the time within which the applicant must proceed after any action by the Patent Office. This does not affect prior applications, but is cited as showing the views of Congress on this subject. And it was held by Dunlop, J., as long ago as 1861, that two years was the utmost that the applicant should wait after a rejection, though there was then no statute to that effect. *Snowden v. Pierce*, Law's Dig., 149. The above cases will be found still more applicable when we come to consider the *amended* application.

It may be said, however, that there was never any abandonment of this application; that the evidence clearly shows an intention to prosecute it; and that unless the parties did intend to abandon it, they were entitled to a patent.

But without any positive act of abandonment, one may yet forfeit his right to a patent by his delay. Of what importance is it if I state every day that I intend to prosecute my application, if I never do prosecute it, or prosecute it with so little energy that long before I am ready "another steppeth down before me?" If no delay will work a forfeiture, then one may wait fifty years or a hundred.

We have thus far assumed that the brake patented was the same as that in the original application. But this was far from being the case. The *Batchelder & Thompson* brake was a "bumper brake," a brake to be operated by the cars crowding upon each other; it was of no value and never came into use. The *Tanner* brake, on the contrary, was not a "*bumper*" brake at all, but wholly a *hand* brake; it was far superior to the other, and has continued in use to this day.

Then, if it be true, as they are forced to claim, that *Batchelder & Thompson* invented this far superior brake at the same time they invented the wretched contrivance shown in their original application, by what right could they keep it from the public all these years? There may have been reason in the claim, that, having filed their application, they thereby showed their intent not to abandon that invention; but this does not apply to the invention for which they obtained the patent. Their first application neither described or indicated that invention. They kept that invention, if they really made it, lying by them five years; and then at last, years after others had invented the same thing, and given it to the public; after others had patented still better things, they filed an amended application in which they described and claimed the *Tanner* brake; the *Nicholls* brake, which was precisely the same as the *Tanner*, having been known at least as early as 1847, and the *Stevens* brake, used by appellant, having been patented in 1851, and the *Hodge* in 1849. If this is diligence and good faith, then those things must have changed their names.

Again, *Batchelder* swears that he saw this brake in use on two other roads in 1850. p. 94. If he did, it was all the more his duty at once so to amend his application as to embrace this device. *Shaw v. Cooper*, 7 Pet. 319–323; *Rawson v. Mayor of New York*, 1 Fish. 272; *Treadwell v. Bladen*, 4 Wash. 708; *Whitney v. Emmett*, Bald. 311; *Kendall v. Winsor*, 21 How. 329; *Walker v. Forbes*, Dunlap J. Law's Dig. 149; *Wilton v. Railroad Co.*, 2 Whart. Dig. 410; *Winans v. Schen. and Troy R. R.*, 2 Blatch. 291, 300.

These cases decide that if an inventor finds his invention in public use, he must at once apply for a patent, or forfeit his right.

II. What has been said above applies solely to the question of delay. But in the next place we insist that the change here made in the character of the invention was sufficient to defeat the patent, no matter when made.

We deny that an inventor has a right thus to change the whole character of his invention. We deny that he may lawfully cancel every part of his original specification, drawings and model, and put entirely new and different ones in their place. He may change the details of construction, but he cannot change its essence. In short, our proposition here is this, that nothing shall be introduced into a patent by way of amendment which is not described, indicated or suggested, either by the original specification, drawings or model. And it seems to us that this Court cannot in view of the law and its own repeated decisions come to any other conclusion.

Section 7, Act of 1836, provides that if the applicant whose claim is rejected persists in his claim, with or without any alteration of his *specification*, he shall make oath anew. And if his *specification and claim* shall not have been so amended as to entitle him to a patent in the opinion of the Commissioner he may appeal. This is all there is as to amendments. And it is noticeable that, while no leave to amend is expressly given, the leave that is implied is confined to the specification. Nothing is said as to the model. The case then is clearly one for judicial construction.

The only case, so far as we know, bearing directly on this question, is *Singer v. Braunsdorf*, 7 Blatch. 521. It is there taken for granted that the power to amend the application is limited as in case of a reissue, and that nothing can be added that is not found or indicated in the original.

In *Godfrey v. Eames*, 1 Wall. 325, this court held that no amendment can be allowed to introduce a "distinct and different invention, and one not contemplated by the specification as submitted at the outset." But the precise question now under discussion was not before the court. The court did decide that the amendment must be for the *same invention*, but not how this sameness was to be determined.

In another class of cases, however, we find decisions exactly in point. The rule first suggested in *Woodworth v. Stone*, 3 Story, 753, in 1845, and afterwards more fully defined in *Carhart v. Austin*, 2 Fish. 553, and other cases on the circuit, viz., that nothing can be included in a *reissue* which is not described or indicated in the original specifications, drawings or model, has been fully adopted by this court. *Seymour v. Osborne*, 11 Wall. 544; *Gill v. Wells*, 22 Ib. 24. And Congress has here followed the courts. By analogy of reasoning, the same rule must be applied to amendments. The reasons which led the courts to establish this rule in the one case apply with equal force to the other. In each case it is a rule plain, simple and easy of application. It leaves nothing for construction. It is easy to see at once if the proposed amendment existed in the original. If it did, there can be no harm in adding it to the patent. If it did not, there can be no injustice in requiring a separate application. No other rule can be found not open to grave objection. Thus it may be said that there can be no harm in allowing any amendment that does not *change the character of the* *invention*, and that there is no need of defining the rule within narrower limits. But the courts have seen fit to lay down a more definite rule as to reissues, and for very good reasons. It is not always easy to tell just what is the "character" of an invention, or whether it has been changed. There is room for a wide difference of opinion on both these points. Thus the right of amendment would be a constantly shifting quantity; it would be allowed by one judge or examiner, and denied by another; while, if nothing can be admitted which is not indicated in the original, we have at once the utmost possible uniformity and precision.

These two analogous sections of the Act are also thereby brought into entire harmony, and we are spared the trouble and confusion arising from having one rule in the one case, and a repugnant rule in the other. In the case of a reissue this court has even gone so far as to say that it would present a question of fraud for a patentee to do what has been done with the original application here. *Brooks v. Fiske*, 15 How. 220. And see *Whitely v. Swayne*, 4 Fish. 127-8.

It may be said, however, that the two cases are not parallel, that the rule as to reissues rests on the act of Congress, while there is nothing of the sort as to amendments.

But this is a mistake. The rule as to reissues is purely one of judicial construction. There is not a word in the act even suggesting it. All that Congress has to say on the subject is that the reissue shall be for the *same invention*. How this sameness is to be proved is left for the courts to determine. The Act then really amounts to nothing; for even without it the courts would have held that to be the law. In fact, this is precisely what they have done in regard to amendments. The Act makes no such requirement, viz.: that they shall be for the same invention; yet this court has not hesitated to insist upon it.

In other words the courts have done for amendments just what Congress has done for reissues. We have reached, therefore, the same point as to both these questions; by different roads, it is true, but one as good as the other. The courts have then gone one step farther with reissues, and held that nothing shall be deemed the *same invention* that is not indicated in the original specification, drawings or model; how can they refuse to take that step with these amendments?

If the court agrees with us, that is an end of the case. If they agree with us that this is a good rule to apply to reissues, and a good rule to apply to amendments; that it is well calculated to prevent perjury and fraud, to save inventors from the temptation to appropriate the inventions of others by foisting into their applications what they never invented, or what others had invented before them, the court will at once pronounce the patent invalid on this ground alone. But the court may not agree with us. They may say for some good reason we have failed to find, that the same rule of evidence ought not to apply to amendments that applies to reissues; that while it is all right and proper to decide the question of identity of invention in the one case by reference to the original specification, drawings and model alone, yet that it is better to decide the same question in the other case in some entirely different way. The court may hold that the record alone shall be looked at in the case of reissues, and yet admit the testimony of experts and other outside evidence in the case of amendments.

But even if the court should decide this point against us, we do not see how it can affect their final decision. The difference between the two machines is so gross and palpable that, no matter what test we apply, or what rule of evidence we adopt, we come to the same end. In construction, operation, purpose and result we shall find them totally unlike.

Before this alleged invention the brake in general use was what is known as the Single Brake, operating on only the four wheels in one truck from one windlass. It is claimed by the patentees that this was the only practicable brake in use on passenger cars, and that they were the first so to connect the two single brakes, with each other and with the windlasses as to enable the brakeman to apply the brakes of both trucks at once from either end. In the patent they do not claim this combination generally, but only when it is effected by means of the vibrating lever A, or its equivalent, or mechanism essentially as specified. We do not admit that there were no double acting brakes previous to this invention, but let us suppose that such was the fact. The patentees will then appear as improvers of the old Single Brake by adding to it the vibrating lever and its connecting rods, so as to combine the brakes and windlasses of the two trucks for the purpose described; thus making what is now known as the double brake acting on all eight wheels at once, instead of only four.

Now we admit that both these brakes, that in the original application, and that patented, have a centre lever, and that both were *intended* to operate on eight wheels from either end of the car; but here all resemblance ceases. Thus, the centre lever in the *Batchelder and Thompson*, Fig. 5, does not operate and was not intended to operate like the centre lever in the *Tanner*. First. It does not receive the power from the windlass, and transmit it to the brake levers, but receives it from one brake lever, and transmits it to the other. Thus one brake lever is operated directly from the windlass, *without having anything to do with the centre lever*, while the other brake lever is operated by the centre lever. As to the brakes in one truck, therefore, the centre lever is wholly idle; the brakes in that truck being operated solely by the chain running from the windlass over the pulley in the frame. We repeat then that in this *Batchelder and Thompson* brake the centre lever is always and necessarily used only to operate the brakes in one truck. In this sense therefore it is only half of a centre lever brake.

Second. This centre lever is so constructed that in operating its one set of brakes, it has both to push and to pull. One of its rods is a pull, and the other a push rod, alternately ; the consequence is that both these rods have to be made very thick and heavy to stand the thrust.

Third. This centre lever does not increase the power of the windlass, and cannot increase it, while at the same time the great loss of power from the use of the pulleys renders this defect all the more serious.

If now we turn to the *Tanner*, Fig. 6, we find little of the old brake left. The clumsy arrangement of pulleys and push rods is discarded ; and in place of them there are four light pull rods attached to the centre lever, by means of which an entire change is effected in its operation. The centre lever now operates both sets of brakes, instead of only one set as before. It is now for the first time truly a centre-lever brake. This centre lever receives the power from either windlass, and transmits it to all the brakes. It not only transmits the power, but largely increases it.

The two rods that run from the ends of the centre lever of *Batchelder and Thompson* to the brake levers, are in the *Tanner* disconnected from the brake levers, and carried over to the two windlasses, and are thus made to perform an entirely new and different function. They have now nothing to do with the brake levers, but their office is simply to move the centre lever.

Then we have two additional rods, not found at all in the *Batchelder and Thompson*, one end of which is attached to the centre lever at some distance from its centre, and the other end to the brake levers in the trucks. We have thus four connecting rods instead of two—all of them tensile or pull rods—and no two of them answering to the two connecting rods in the *Batchelder and Thompson*.

The change thus made is in the highest degree important. It is not the addition merely of two new rods, leaving the other parts unchanged, though that would be enough to make it an essentially different device ; but it is far more than that. It involved the making over of the whole machine. *It represented all that difference, so often insisted on by the courts, between failure and success.* Instead of a brake that has never been in use, even on a single car, and that never would or could have been used, it has given us a brake that has been in use from that day to this.

In the next place the *purpose* of the two brakes was wholly different. The *Batchelder and Thompson* was nothing but a *bumper brake*, to be operated by the crowding of the cars.

The specification starts out with the statement of invention. In this the letters A, C, D, H, and I are the parts claimed as their improvements. p. 135. A is the two rods running to the center lever ; C the point where these rods are attached to the brake lever, and where the brake levers unite with the "butters" by means of a gain ; D is the center lever ; H the long rod under the car, and I the knobs fitted to the bends in rod H. p.137.

All these are parts of the *bumper brake*, and C, H and I are not used for anything else. "J is a purchase attached to the connecting rods, by which the brake may be applied by hand at pleasure, without reversing the engine." This purchase J, it must be noted, includes not only the windlass but also the chain and pulley round which the chain is made to pass. It is the only part of the whole contrivance that gives any color to the claim that this brake was ever intended for a hand brake, *and it is not claimed as any part of the improvement.* And when the specification says that the brake may thus be applied by hand at pleasure, without reversing the engine, it does not mean that it is to be used as a hand brake, but simply that this is another way of applying the *bumper brake without reversing the engine.* That is, the hand brake is applied *on the foremost car*, thus slackening its pace, the other cars crowd on it and on each other, and thus the bumper brake is applied through the whole train. That is what is meant by "*without reversing the engine.*"

What follows is conclusive on this point.

"The operation is thus: while the engine is attached to the cars, the engineer can operate on the brakes throughout the whole train by slacking the speed of his engine, and bringing it back against the butter, and so applying the power to the lever B. WHEN THE ENGINE IS DETACHED ONE BRAKEMAN IS SUFFICIENT TO DO THE WORK OF ANY NUMBER OF CARS." p. 137.

We have here two methods described of using this brake and only two, and both include the use of the bumper. In the one this result is brought about by reversing the engine; in the other, the engine being detached, the same result is effected by slackening the foremost car. In that way and no other can "one brakeman do the work of any number of cars."

We say then that all which *Batchelder and Thompson* then had in mind, all that they then supposed they had invented, was this worthless and impracticable *bumper brake*, intended in certain cases, it is true, to be set to work by hand, but none the less a *bumper brake*, and nothing but a *bumper brake* all the time.

Next as to the result. The *intended* result of the *Batchelder and Thompson* brake we have just seen; its real result was absolute failure and abandonment. According to the testimony of *Batchelder* it never was applied even to a single car; as we believe it had two trials and failed in both. It matters not, so far as this part of the case is concerned, which of these theories is correct; it is sufficient to know that the *Batchelder and Thompson* brake was wholly worthless, so worthless that even its inventors never cared to try it, or tried it twice and then abandoned it forever.

It is true that the same *Cooper* who, as examiner in the Patent Office, drew the claim for *Tanner*, and allowed the patent, and who is now brought forward as an expert to swear this case through for the patentees, gives it as his opinion that "the invention claimed in the *Tanner* patent is *embodied* in the model originally deposited with the *Batchelder and Thompson* application; it is also represented in the drawings and described and *distinctly claimed* in the original application," etc., etc. p. 106.

But in the first place no expert testimony can be received upon this point, but it must be settled by the court on an inspection of the papers and model alone; and in the second place this same *Cooper* had returned the papers "*for entire insufficiency;*" and if he did not write, he must have approved the previous decision of the office on which that letter was based, as follows:

> "The specification and drawings are very defective. The specification does not describe the nature, construction, or operation of the alleged improvement. The claim is the application to car, brakes to prevent collisions, and so forth. The claim must be clear and specific. The claim here set up would cover every kind of car brake. The drawings do not illustrate the character of the brake." p. 138, 121.

The question then is, Can such a radical change in an invention be allowed at any time under the guise of an amendment? Can it be made five years after the filing of the first application? And especially years after others have given the same thing to the public? And all with the purpose and result of forestalling these earlier and more diligent patentees, and compelling them, and those who in good faith have bought of them, to pay over again for what they cannot but regard as an unjust and fraudulent claim?

This last consideration seems to us controlling, and has always been so regarded by the courts. A delay, that might otherwise be passed over, will be fatal where others have in the meantime invented and made public the same thing. And the reasoning applies with equal force to this change in the invention. If such a change ever could be lawful, it could only be when no independent inventor had already made the same invention.

III. THIS CHANGE IN THE INVENTION, BAD ENOUGH IN ITSELF, BECOMES FAR WORSE WHEN WE SEE HOW AND BY WHOM IT WAS MADE.

This whole transaction is without a parallel. The first application was made in June, 1847. It described the *bumper* brake now familiar to the court under the name of the *Batchelder and Thompson* brake. That application was stayed by them for the purpose of making new improvements, which were never made; in October, 1850, the papers were withdrawn from the Office by *Eddy*, and after a further delay of nine months again returned without amendment, p. 139. For five years *Batchelder and Thompson, Bellows and Heath and Eddy*, kept this bumper brake in the Patent Office, and not a word do we hear in all that time from one of them as to any other. And not a word should we have heard from that day to this if it had not been for the occurrences we are now about to relate.

As early as 1847, and, as we shall attempt to show hereafter, a year earlier, one *Nicholls* invented a brake which is admitted to be the same as the *Tanner*. This brake was soon after brought into use upon the Hartford and New Haven Road, where it proved a success; but for some reason *Nicholls* never applied for a patent. p. 146–158.

In November, 1848, one *Turner* obtained a patent for a double brake bearing some resemblance both to the *Batchelder and Thompson* and the *Tanner*. It was a bumper brake, and hand brake combined. It had also a centre lever, but not arranged like the *Tanner*. This *Turner* patent was bought by *Tanner* the same who gave his name to the *Tanner* patent, and who now for the first time makes his appearance on the stage. He found it difficult to introduce this brake on account of defects we need not explain, and while travelling for that purpose, he also found the brake previously invented by *Nicholls*, as above mentioned. He must have become satisfied also that the invention of *Nicholls* anticipated that of *Turner*, for in 1851 he made a bond for the benefit of *Mrs. Nicholls*, then a widow, to secure to her a sum of money from the collections that might be made on this center lever in the *Turner* patent. About the same time he also had a model made of this centre lever, separating it from the self-acting, that is, the bumper part of the *Turner* brake, making it in all respects like what is now known as the *Tanner*, and he used this model in exhibiting the *Tanner* Patent for sale, after that patent was issued to him. pp. 536, 539, 540, 542.

In other words he threw away the *Turner* brake, and substituted the *Nicholls* brake in its place, justifying himself in this, no doubt, by the bond given to *Mrs. Nicholls*, and which he evidently regarded as a purchase from her of whatever rights she might have had under her husband's invention. Having taken this first step the rest was easy. As *Nicholls* had no patent under which *Tanner* could protect himself, he had to look elsewhere, and he had then no where to look except to the *Turner*. By a masterly stroke of policy he determined to reissue the *Turner* so as to make it include the invention of *Nicholls*. The reissue was prepared, and a claim drawn up by the same *Cooper* already mentioned. He wrote that claim, and suggested it to *Tanner* as one that he would allow on that reissue. p. 542.

Thus fortified and encouraged *Tanner* goes to Washington to obtain his reissue, but there he comes across what might then fairly be called the abandoned application of *Batchelder and Thompson*. He finds that it also is prior to the invention of *Turner*, possibly to that of *Nicholls*. Here then is another obstacle in his path, but he was equal to the emergency. He goes at once to buy out *Batchelder and Thompson*, as he had already bought out *Turner* and *Nicholls*; he obtains from them an assignment of their invention, then hastens to inform the office that he is now owner of both, the *Turner* and the *Batchelder and Thompson*, and that so there will be no need of an interference. p. 140. He is even willing to give up his reissue of the *Turner* if they will only grant the patent to *Batchelder and Thompson*, with the same claim he had already had prepared by *Cooper* for that reissue. That claim, as the court will see, was of the most elastic nature, and in terms fitted equally to any of these three brakes, the *Batchelder and Thompson*, the *Turner*, the *Nicholls*, or in other words the *Tanner*. p. 542.

A bargain is struck on this basis between *Tanner* on the one part, and the Patent Office, represented by *Cooper*, on the other; a bargain in which *Tanner* had everything to gain, and nothing to lose; the new specification is drawn with new drawings, both adapted to the *Nicholls* brake; the claim prepared for the *Turner* reissue is annexed with some slight verbal changes, and the new application is filed, all in the name of *Batchelder & Thompson*, and a patent demanded in the name of *Tanner*, their assignee. But one difficulty still remains. The old model does not harmonize with the new drawings; this new wine will burst the old bottles; thereupon the *Turner-Nicholls* model is sent to correspond with the new specifications and drawings, and the poor old model, specification and drawings of *Batchelder and Thompson*, having served their turn, are cancelled, p. 141.

The change is now complete — no one would recognize in this new applicant knocking at the door of the Patent Office the wretched abortion of *Batchelder and Thompson*.

But is this impostor to succeed? Will this court allow this so-called amendment to stand? Before doing that we beg the court to note these things. First, the *Nicholls* brake, which was precisely the same as the *Tanner*, had been invented and put in use at least as early as 1848. p. 147. Second, *Tanner* had found out the existence of this brake, and had boldly put it in place of the *Turner* into the *Turner* patent. p. 540. Third, on finding the *Batchelder and Thompson* application in the Patent Office, he repeated his former experiment, and put this same *Nicholls* brake into that. p. 140, 542. Fourth, *Batchelder and Thompson*, *Bellows*, *Heath* and *Eddy*, had kept their old bumper brake in the Patent Office for nearly five years, without a word as to the *Tanner* brake. Fifth, but the moment *Tanner* comes into the case the *Tanner* brake comes with him. Sixth, this *Tanner* brake is so infinitely superior to the old *Batchelder and Thompson* that it is difficult to believe that the same parties could have invented both, still more that they should have had this vastly superior brake lying by them all the time, and never made application for it. Seventh, *Batchelder et al.* had been trying, as they say, nearly five years in vain to obtain a patent, but as soon as *Tanner* appears, the patent is obtained without trouble.

The case of *Whitely v. Swayne*, 4 Fish. 127–8, is here strikingly in point.

"Until the year 1860 it seems to have been, if not among the lost arts, at least among the lost things of earth. The complainant, by means not proved in the case, obtained knowledge of the existence of Steadman's patent, and in 1860 obtained an assignment. What consideration, if any, he paid does not appear. It may be presumed it was merely nominal. But the complainant was doubtless aware that, though Steadman's invention was worthless for the only purpose for which it was invented, the patent was nevertheless valid, and could be assigned in law. There is no reason to suppose that complainant in procuring the assignment intended to avail himself of the machine, as a cloverseed and grass harvester. This is apparent from the fact that he has not constructed or authorised others to construct the machine since the assignment. The irresistible inference, therefore, must be—and this inference is sustained by his subsequent conduct—that his intention was to surrender the patent, and *by some artful change in the description of the machine, some additions to the devices described and claimed by Steadman, to obtain reissues enlarging the scope and operation of his invention, and thus to metamorphose the machine into a grain harvester; or, if that failed, so to change the specification as to cover certain elements and combinations then used or to be used in grain harvesters and mowers, or other machines, and thus to lay those constructing, vending or using such machines, under contribution to him as infringers of his reissued patent. If such was the purpose of the complainant, his conduct was tainted with fraud from the beginning.* And in confirmation of this I quote the following from the opinion of the Supreme court in *Brooks v. Fisk*, 15 How. 220: 'It is deemed proper to remark that the fact of procuring a patent for a new and useful machine in 1845, under the assumption of a reissue, which was not useful in 1828, for want of feed and pressure rollers now used, as alleged in defense, would present a question of fraud committed on the public by the patentee, by giving his reissued patent of 1845 date as an original discovery made 1828; thereby overreaching similar inventions made between 1828 and 1845.' "

And see what follows on p. 129.

We think then there is no doubt the patent was invalid as issued to *Tanner*. If so, it could not become valid in the hands of *Sayles*, even if *Sayles* had been an entirely innocent purchaser without notice. A fraud thus committed on the government and on the public will follow the patent, into whatever hands it may come.

But *Sayles* was not a purchaser without notice. He knew all about the transactions above narrated. He knew all about the *Turner* brake and the *Nicholls* brake. He assumed payment of the bond given by *Tanner to Mrs. Nicholls;* he was several times at her house, talking over this matter, and examining books and papers; and he promised her a handsome present in case the suit against the Hudson River Road succeeded. pp. 150, 151, 155. He knew of course all about the delay in the application, and he knew about the change made in the character of the invention, for these things were matters of record.

We claim then that, whether *Batchelder & Thompson* invented the *Tanner* brake or not, the patent was invalid; but

IV. THERE IS VERY GRAVE DOUBT AS TO THEIR HAVING ANYTHING TO DO WITH THAT INVENTION.

If the case was to be tried on the evidence already presented, we think there could be no doubt in the mind of anyone.

In the first place it is hard to believe that men capable of inventing the *Tanner* brake would have kept it back all these years, and presented only their wretched bumper brake before the Patent Office. As it is well put by *Wm. D. Bishop*, Esq., when resisting the application for an extension before Congress, "If you should go down to the seashore, and see a man bailing out a boat with a clam shell, when he had an empty bucket at his hand, you would say he was a fool; and any man of common understanding, no matter what the testimony may be, cannot believe with his eyes open, and his senses about him, that *Batchelder and Thompson* in 1846, invented the *Tanner* brake, and yet in 1847 produced the *Batchelder and Thompson* brake as their invention."

So in *Potter v. Fuller*, 2 Fish. 265, the court arguing a similar question says,

"If Bachelder" (not this Batchelder) "had previously invented and put in operation a machine that worked so well and effectively as an examination of Exhibit J. B. shows that it does, *it is inconceivable* that he should have exhibited at fairs and made models of machines with dog-fish skin rough surface, and afterward have applied for a patent for that as an improvement upon his previous patent."

In the second place, it is still harder to believe that *Batchelder and Thompson* invented the *Tanner* brake in 1846, when we find how and by whom it at last really got into the case. It is an undisputed fact that it was got there by *Tanner*, and that *Batchelder and Thompson* had nothing to do with it. Yet after this we are asked to believe that they had five years before invented the same thing. Nay more, we are asked to believe that it was their *first* invention, and that the *Batchelder and Thompson* brake came after. All this is more than an ordinary coincidence; it comes very near being a miracle. It certainly makes out the very strongest kind of a *prima facie* case against the patentees. This being so, we think every one would suppose that the plaintiff would produce all the evidence in his power to rebut it. This court will probably assume that the plaintiff has called on this point, not only *Batchelder and Thompson*, but *Bellows*, their first assignee and helper; *Heath*, who came after *Bellows*; *Eddy*, the able patent solicitor, who had the matter in hand for years, and finally procured the patent; *Tanner*, whose business it was to inquire fully into the matter from the beginning; together with such other witnesses, if any, as were knowing to the invention.

But such is not the case. Neither *Thompson*, nor *Heath*, nor *Eddy*, has ever been examined at all. *Tanner* has given his testimony, but not on this point. The only witnesses for the plaintiff are *Batchelder and Bellows*; when we read their testimony we shall perhaps see why the plaintiff did not see fit to call any more.

Bellows was a physician in Charlestown in 1846 or 7; and became part owner of the *Batchelder and Thompson* invention soon after; he paid money for it, and must be presumed to have known what that invention was. On being called by the plaintiff, and shown a model of the *Tanner*, known here as the "*Batchelder*" model, he says:

"I saw this model, *or a model representing the same double-acting brake like this*; I *think* this is the same model shown me by *Thompson* in latter part of 1846, or first of 1847; some time after I engaged to assist in making a *practical* *application of this principle* to a car on the Fitchburg Road. This brake was put on the Fitchburg car under my own observation in the fall of 1847." p. 89.

The "*Fitchburg*" model being then produced, he says:

"This model *seems* to represent *the principle* of the brake as applied to the Fitchburg car." p. 89.

On cross-examination, being asked how he identifies the "*Batchelder*" model as the one shown him in 1847, he says, "He identifies this arrangement of levers by which both sets of wheels are acted on by one windlass;" and again, "that he is positive the 'Fitchburg' model *represents the principle* as applied to the car under his observation; that he was told that models like either of those filed in the case was filed in the Patent Office, but does not know." p. 90.

It is not enough to say that this evidence proves nothing for the plaintiff; it is more in favor of defendant. We have a right to argue that this was the best that plaintiff could do. Yet this witness only swears to a "*principle*;" a conclusion of law. "*The model represents the principle*"—he identifies this arrangement of levers *by which both sets of wheels are acted on by one windlass;*" all quite as applicable to the *Batchelder and Thompson* brake as to the *Tanner*, and not tending to raise the slightest presumption in favor of either, except on the principle that being plaintiff's witness his evidence must be taken most strongly against him.

We come next to *Batchelder* himself. He, as was to be expected, swears more positively than *Bellows*, and he says that the "*Batchelder*" model is the original model made by him, that is that this *Tanner* brake was their first invention. "All that is on it now was on it when I first made it; but there was also a *bumper* arrangement put on it at the same time, which was not now on the model. The model was made from the drawings made by *Thompson* and himself in October, 1846." p. 93.

"I made another model for the Patent Office in March or April, 1847; carried it to Boston and left it with *Heath*. We tried the brake on one car on the Fitchburg road in October, 1847; after we got it arranged, we made one trial trip; it worked to our entire satisfaction; the next summer I put it on a car on the Lowell road; I only put on the hand braking on the Lowell road; on reflection I am satisfied I put it on the same as on the Fitchburg car. The model (the 'Fitchburg' model) represents the precise arrangement as it was put on to the Fitchburg car. * * I think it remained on from October to the next spring. *Thompson* wrote me he had ordered it off."

On cross examination he says that a brake like the B. & T. P. O. model was never applied to a car; that neither he nor Thompson had had any practical knowledge of railroad machinery when they set to work to get up a brake; that he has been reading his answers or some of them from manuscript previously prepared; that he explained to *Heath* their brake in all its details, and what they claimed as their invention; that stiff rods like those in the Patent Office model had been put at one time upon the "Batchelder," and also the long rod H, running under the car; that they substituted the brake patented in place of the other because they considered it much easier, cheaper and easier applied; that *G. B. King*, master mechanic of the Lowell road, had sworn, in the case of *Sayles v. Phil.*

& Bal. Road, that the brake, as applied on the Lowell road, was put on with large rods as in the Patent Office model, and that, on applying for leave to try their invention on the Fitchburg road, they showed him the "Batchelder" model, *which was then arranged like the Patent Office model.* p. 96–104.

Being asked whether he had been made to understand that he must fix the date of his drawings not a month or six weeks later, and that the brake must be complete in all its parts as seen in the "Batchelder" model, or his evidence would be of little use to the plaintiff, he replies, "I have no *recollection* of any such thing." Again, being asked whether much of his evidence had not been framed for him by the plaintiff, instead of giving it a flat denial, he says, "I think I am capable of acting and speaking and thinking for myself." p. 103.

Finally, while attempting to explain this mystery, the very thing he most carefully avoids is that which most needed explanation. What we want most to know is, how it happened that they kept the *Tanner* brake in reserve from 1847 to 1852, and then brought it out just as *Tanner* came into the case. Did he propose the change, or did they? How was *Thompson* induced to give up his bumper brake? We would have liked to know the conversation that took place when *Tanner* and *Batchelder and Thompson* first came together; how they satisfied *Heath*, and what explanation they gave to *Eddy*. But all this is a sealed book. *Batchelder* has forgotten "how he expressed himself to *Tanner*," and no one else is here to tell us.

Now the question is, Is this evidence of *Batchelder* enough to overcome the *prima facie* case above presented? We insist that it is not: because he is an interested party; because some of his answers, we cannot tell how many, were prepared for him in manuscript, while others are evasive; because he is not corroborated by *Thompson*, or *Heath*, or *Eddy*, or *Tanner*; and because he fails to explain the most essential fact in the case.

Again he admits that the brake shown to *Turner*, master mechanic of the Fitchburg road, was the same as the old *Batchelder and Thompson* bumper brake; though, as actually put on, he would have us believe it was the *Tanner* brake, p. 102.

Again, if the *Tanner* brake was in fact put on one car on the Fitchburg Road and also on the Lowell Road, and "worked to their entire satisfaction," why was it never applied on any other car on either of those roads? Why did both those roads go on using the single brake on all their other cars till 1851, and then adopt the *Hodge?*

The court below, speaking of the alleged prior use of a double brake on the Camden & Amboy Road, insists that such a thing is well nigh impossible: "If it were true that a double acting brake of the kind included in the model of the John Tyler car existed in 1843, *it is scarcely possible to doubt that it would have gone into general use at once on the road*," p. 67.

We do not agree with this reasoning, for that is not the way improvements are made on railroads; but as the argument was thus used against us in another part of the case, we are entitled to use it here.

Finally if *Batchelder and Thompson* really invented the *Tanner* brake in 1846, why were *Tanner and Sayles* still so anxious in 1853 to placate *Mrs. Nicholls*, as it seems they were from their promising her a present in case the Hudson River Railroad suit was decided in their favor, and from *Tanner's* letter of Nov. 11, 1856? p. p. 150, 155.

We insist then that the patent is void for the delay in following up the application; if not for that, then for the change in the character of the invention; if not for either or both of these, then because others had in the meantime invented and published the same things; if these still are not sufficient, then because of the manner in which this change in the invention was brought about. There is not one of these reasons but what seems sufficient, but we need not rely on any one of them alone. It is the cumulative weight of all these facts together to which we especially invite the attention of the court.

II.

THE QUESTION OF NOVELTY.

We next insist that Batchelder and Thompson were not the first inventors of this brake; and to prove this, present four prior inventions. The *Millholland Brake* — The *Stanley-Talson* — The *Camden and Amboy*, and the *Nicholls*,

I. THE MILLHOLLAND BRAKE, pp. 79–86, and 158 to 167, was applied by James Millholland on the Baltimore & Susquehanna Road as early as 1845.

In place of the Tanner center lever it had a drum under the bottom of the car, with four rods running to it by which all the brakes could be applied at once from either end as in the Tanner — the drum performing all the functions of the lever. It is not quite clear how long it was used; it may have been a year or only a few months, but if the same as the Tanner this is not important. That it was substantially the same as the Tanner can, we think, be readily made to appear. The invention in the Tanner patent is the means employed to connect the two sets of brakes. "What we claim is to so combine the brakes of the two trucks with the windlass *by means of the vibrating lever A or its equivalent*," etc. The trucks, the brakes and the windlasses were the same as in the old Single Brake; all that was done in the Tanner was to add this centre lever and make the necessary connections. But the Millholland drum is the full equivalent of the lever. That lever is only two spokes of a wheel, and a wheel is only a shorter drum. Then as to the four connecting rods of the Tanner they are all found without any change in the Millholland. If the Millholland had come after the Tanner, it would clearly have been an infringement. Or if Millholland had obtained a patent, as he certainly might have done, with a claim for "combining the two sets of brakes by means of the oscillating drum or its equivalent, so as to apply all the brakes at once from either end of the car;" can there be any doubt that the Tanner Brake would have been an infringement? And would it have required any invention to substitute the lever for the drum?

But the fact that he never got a patent makes no difference, neither does the fact that it was abandoned. *Many v. Sizer*, 1 Fish. 21; *Colt v. Mass. Arms Co.*, Ib. 115; *Case v. Brown*, 2 Ib. 272; *Rich v. Lippincott*, 2 Ib. 7, 8; *Whipple v. Baldwin Man. Co.*, 4 Ib. 32; *Evans v. Eaton*, 1 Pet. C. C 323.

> "We must distinguish between the invention and the machine. The invention may be perfect, and the machine imperfect. If the prior machine was identical in invention it is immaterial though it required more adjustment of parts or mechanical perfection to make it work as well as the plaintiff's." *Amer. Hide and Leather Split. and Dres. Mach. Co. v. Amer. T. and M. Co.*, 4 Fish. 306, 7.

It is said, indeed, that the drum is rigid and unelastic, and has no effect to increase the power. But it is no more rigid and unelastic than the lever; it is absurd to talk of a bar of iron two feet long and three or four inches wide being elastic in the direction of its width; and as to multiplying power, the lever will not do that any more than the drum if the rods from the brakes run to its extreme ends as is sometimes the case; but no one would think of claiming that it was any the less the Tanner lever on that account. Moreover the drum can be made to increase the power as well as the lever and in the same way, viz., by attaching the brake rods nearer its centre, as shown in Fig 12.

Or leaving the drum just as it is, we can obtain all the power we want by simply restoring the brake levers found in the old Single Brake. The trouble with Millholland is not in the drum, it is in the trucks. And surely after Millholland had invented this drum, after he had shown how the two sets of brakes could be combined, there could be no invention in substituting for his truck-levers the well-known arrangement so long used in the Single Brake. The defects in the Millholland had nothing to do with the drum, the particular part in question, and those defects therefore ought not to be regarded. *Pitts v. Wemple*, 2 Fish. 10.

II. THE STANLEY-TALSON BRAKE, pp. 289–303, was applied on the New Jersey Railroad and Transportation Co., in 1842. It had a centre lever, the same as Tanner's; but the arrangement in the trucks seems to have been somewhat different. To simplify the case we admit that it was used only a short time, and was abandoned. For this various reasons are assigned. One of plaintiff's witnesses swears that *Talson* said to him that

> "He claimed it operated precisely like the *Tanner*. I recollect asking him this question; if it operated precisely like the *Tanner*, why it was subject to these break-downs; why it should break when operated, as the *Tanner* was not subject to do? His reply was, that it was because it was not properly constructed; that the materials were not of sufficient strength, and that in applying new machinery you could not always tell what particular strength to give particular parts—and that it was an experiment."

Another witness says when asked what was the trouble with it: "It appeared to be light, so that it would break."

Acting on this view of the case the plaintiff claimed that this brake was an abandoned experiment, and as such could not defeat the patent. Much of the argument in regard to the *Millholland* Brake applies equally here. In addition we suggest first, that nearly all the difficulty in which this class of questions is involved is due to the ambiguous use of the word "*experiment.*" There are two kinds of experiment. One is where attempts are made to produce the machine, but without success. There is no doubt that this class of experiments is not sufficient to defeat a patent. The other class is where the machine is produced, but owing to its weakness of material, or some mistake as to size or proportion, it breaks or fails to do good work.

Now if we apply the same rule to this class of experiments, and follow out that doctrine to its logical results, we shall find ourselves involved in gross absurdity. Thus, suppose A to invent a revolving pistol which on being tried bursts, because the iron is poor or too thin, or because the parts wanted nicer adjustment; and suppose he makes his invention public; will it be pretended that B can obtain a patent for that identical pistol, simply by making it of a little thicker or better iron, or by a more careful adjustment of parts? Yet if it is an abandoned experiment in the proper sense of those words, there is nothing to prevent. Nay more, he may even obtain this patent though he has full knowledge of all that had been done by A, though he has stood by and watched all his operations. For the law presumes the inventor to have full knowledge of all that had been done by others before him.

And whether he knows of these prior attempts or not, if they are abandoned experiments, they go for nothing. In short, an abandoned experiment is to all intents and purposes the same as though it had never been. Hence it follows, to take this very case, that the parties who stood by while *Talson* applied his brake, might any of them have obtained a patent for it, simply by making it strong enough for its work. Whereas, if *Talson* had never made a brake, if he had never taken the first steps towards it, but had contented himself with showing how to make it in a printed book, it would have been impossible for any one ever after to obtain a patent for it, thus showing that the pen is not only mightier than the sword, but better than a whole chest of tools besides.

It seems to us that no better rule in such cases can be found than this: If the prior inventor has gone so far that a printed description of his machine would suffice to defeat a subsequent patent, he has done enough. His work may be only by way of experiment, he may never give it more than a single trial, or he may never try it at all; he may then and there abandon it, no matter for what reason; still, if he has made it public, it is enough — no one else can after that obtain a patent. We thus produce entire harmony between the two provisions of the Act. And certainly Congress never could have intended that a thing merely described in a book should have any greater effect than the same thing actually done.

We know there are cases which, read literally, and without regard to the facts, give a different view of the law. But in most, perhaps all, of those cases, the prior machine was either never completed or was not on the same principle as the patentee's. We think no case can be found in which a prior machine was held insufficient to defeat the patent, simply for want of strength.

In *Jones v. Pearce*, Web. Pat. Cases, 124, cited by plaintiff, one of the questions left to the jury was whether the prior wheels were constructed and operated on the principle of plaintiff's invention. On this point there was conflicting evidence. Curtis on Pat. § 89. There is nothing in the case to intimate that if *Strutt's* wheels had been the same as plaintiff's, and had been used a year they would not have defeated the patent, except the implied instruction that such use must have continued up to the date of the patent, which certainly is not the law.

In *Galloway v. Bleaden*, Web. Pat. Cas. 521, the case turned on the question whether "the subject of the patent was the very discovery which the prior inventor had himself made," p. 528. And on page 526 the court says to the jury, "The question you are to determine is whether on the evidence the thing itself was complete, so as to be used, or whether only a series of experiments were going on."

In *Household Co. v. Neilson*, Web. Pat. Cas. 708, the court below had ruled that the prior use must come down to the time of the patent; that the use even of machines of the same sort, if abandoned, would not be sufficient. But this was held to be error, and the Lord Chancellor says, "I never heard it before questioned that the notorious public use of the invention before the granting of the letters patent, though it may have been discontinued, is sufficient to invalidate the patent." And the judges all agreed that if the invention be perfected, "the abandonment becomes wholly immaterial," which is precisely the doctrine we are here contending for.

The true rule on this subject seems to be laid down in *Marshall v. Mee*, Dunlop, J., Law's Dig. 314. "An imperfect and incomplete invention resting in mere theory or an intellectual notion, or in uncertain experiment, and not actually reduced to practice, *and embodied in some distinct machinery*, is not patentable under our laws." And so *Winans v. Danforth*, Nelson J., Law's Dig. 603.

Another very proper test is one already noted under the *Millholland*. Has the first inventor gone far enough to entitle himself to a patent? If he has, and makes his invention public, certainly no one else can have a patent. But there can be no doubt in this case that *Talson* might have had a patent. Nor that the *Tanner* brake would have been an infringment of that patent. This is the test applied in *Allen v. Hunter*, 6 McLean, 321.

If we accept this test it is conclusive. For if *Talson* could have had a patent *Tanner* could not. *Talson* did not abandon his invention to *Tanner*, but to the public. It is not like the safe case, where the invention was known only to the inventor. The use of Talson's brake was open and notorious and known to many.

That this use was for a short time only, can make no difference. *Bedford v. Hunt*, 1 Mas. 305; *Watson v. Bladen*, 4 Wash. 583; *Rich v. Lippincott*, 2 Fish. 7; *Parker v. Ferguson*, 1 Blatch. 407.

In this case a witness stated that he made a wheel embracing the principle of the plaintiff's invention; it was caried away and he never saw it again. Held by Nelson, J., sufficient to defeat the patent, without proof that the wheel was ever actually used.

III. THE NICHOLL'S BRAKE; pp. 146–158, was the same as the *Tanner*, and was used successfully for years. The only question is as to the date of invention; and as to this the evidence is brief. The principal witness is *Mrs. Nicholls*, now Mrs. Allen. p. 148. Her testimony is remarkably minute and circumstantial, and bears all the marks of truth. If she is to be believed her husband made his first drawing of the brake in the spring of 1846, and applied it on a car previous to May, 1847. He would thus anticipate *Batchelder and Thompson*, who, made their drawings in October, 1846, and did not apply their brake till October, 1847; p. 93.

The court below says on this point, "But I think the weight of the evidence is that the *Nicholls* brake was not invented until the spring of 1847, and was not applied until 1848. We have constantly to bear in mind, in weighing the testimony of witnesses who speak of circumstances occurring many years ago, the liability to mistake the particular year, unless they have some evidence of a documentary character, or otherwise, or some leading fact as to which there can be no error, upon which they may rely to show the particular time. This brake was applied upon what is termed a long baggage car. The witnesses, *Stockbridge* and *Fields* state that this car was not finished till the spring of 1848. Various other witnesses differ as to the time from *Mrs. Nicholls*; and she differs now herself in giving her deposition from what she stated in the case in New York some years ago. Besides she took an account book to *Fields*, and inquired of him as to the time her husband put on the brake, which shows that she really had no memory as to the time," etc. p. 64.

With all respect this seems to us a little unsound. For first, as to the liability of witnesses to mistake the year, etc., this applies just as much to plaintiff's witnesses as to *Mrs. Nicholls*. They produced no "evidence of a documentary character—nor any leading fact as to which there can be no error," any more than she; in fact, not so much; for she fixes the time when she went out at her husband's request to see the brake in operation in a way that every woman, or every woman at least who has ever been a mother, will fully appreciate. The court would seem to imply that the long baggage car, on which the brake was applied, was "evidence of a documentary character," or a "leading fact as to which there can be no error;" but that car was no more a leading fact than the brake itself, and not a tenth part so leading as the child *Mrs. Nicholls* then carried in her womb.

Again, the court below seems entirely to have overlooked the fact that this brake was first applied, not on this new large baggage car, but on an old baggage car the year before; p. 156, at bottom.

Again, *Fields* does not state that this car was not finished till the spring of 1848. What he does say is that "*Nicholls* had such a car built, *but I couldn't tell when it was finished;* I should *think* it was finished in the spring of 1848—*to the best of my judgment; cannot tell positively;* I worked on the car considerable; *think* I worked on it in 1847, and 8; *think* some of the work was done during the last year I worked there;" p. 133.

Stockbridge does state positively that he commenced work there April 1, 1848, under *Nicholls;* after he had been there a short time *Nicholls* directed him to apply a double brake to a new long baggage car. But he does not state how new this car was, nor whether that was the first time the brake had been applied to it, nor whether the brake had not been previously applied on another car. But he does say that he has a faint recollection that some of the men said it had been previously applied, and taken off, on account, he thinks, of its not working well. p. 126.

And what is equally noticeable, he says not a word about *Fields*, but tells us that he himself put on this double brake; while on the other hand *Fields* says nothing about *Stockbridge* except that he recollects he was there when he (Fields) left; but says that the brakes were altered several times, and he recollects taking them off once himself. p. 134.

But the court says again, "Various other witnesses differ as to the time from *Mrs. Nicholls*," p. 64. The only other witnesses are *Leppens* and *Hebard;* and they, instead of differing from *Mrs. Nicholls* as to the time directly confirm her. *Leppens* swears that he became acquainted with *Nicholls* in March, 1846; that they built this long baggage car in the fall of that year, and attached to it the *Nicholls* brake; and that this car with the *Nicholls* brake attached, was running as early as March or April, 1847. The brake was applied in three different ways. It is true, he does not remember *Nicholls* showing him the drawing as stated by *Mrs. Nicholls*, and he *thinks* it wasn't more than three months before the brake was applied to the car that *Nicholls* explained to him his invention; he also says that when *Nicholls* showed it to him, he spoke of it as an invention he had just got up. p. 147.

But no one supposes that this invention was got up by *Nicholls* in a day. He had conceived the idea in the spring of 1846; had made various drawings of it during that summer; had finally settled upon the form he liked best, and in that form applied it to a car, first on an old baggage car, and then on this new car. And after putting it on the car he continued to try it, with various slight alterations in the hooks, the length of the centre lever, etc., till all these details were arranged to his satisfaction.

Hebard, the only other witness makes all this perfectly plain. He began work for the Hartford & New Haven Road in August, 1845; and in April or May, 1846, "agreed" with *Nicholls*, then foreman of the car repairs. "I can't tell the time when we commenced talking about the arranging of a brake, but it was during the winter of 1846–7." He then goes on to describe how he, under the direction of *Nicholls*, made and applied the brake. It was first applied to *an old baggage* or passenger car; and there were repeated alterations as above shown. This was in the winter, the writer says again, of 1846–7. During all that winter we were at work on *a new baggage car*. These new brakes which Mr. *Nicholls* ordered made were *put on this new car*. There had to be a new centre lever made. This new brake was perfected on this new car. p. 156.

He left the road late in the fall of 1848; and then this brake was on two passenger cars, and this new car, and was put on baggage cars as they were repaired. "I remember perfectly the appearance of Mr. *Nicholls* the first time he tried the brake in bringing up a train. It was early in the spring of 1847, or the spring after I done the work. My impression is it was pleasant weather, but cold; he had an overcoat on, buttoned up. It was his triumphant look that impresses it upon my mind." p. 158.

Being afterwards called by the plaintiff, and thus made his witness, he says:

> "I testified that it was my impression that it, *the new baggage car*, was finished in the spring of 1847; my impression is the same now. I know of nothing to vary it; I have nothing to fix the date as to when the car was finished; I can 't fix the time when the car was finished any better than the time when *Stockbridge* commenced; to the best of my belief that car was built in the winter of 1846 and 1847. I can 't be positive but I think it was finished in the spring of 1847." p. 125.

Now if we admit that this witness is too uncertain to be of much value as to the time, and set off that part of his evidence against the plaintiff's witness *Fields*, who is yet more uncertain, we shall have two witnesses, *Leppens* and *Mrs. Nicholls*, to offset one witness *Stockbridge* — and the two witnesses who knew more about this matter than any others.

But it may be said *Stockbridge* cannot be mistaken as to the time, because he swears by the books. But why cannot a witness be mistaken as to what is contained in a book as well as about any other fact? If indeed he had produced the books, or if he had even told us what was contained in the books, or when if ever he had consulted the books, it would be different. But he tells us none of these things. This evidence then is purely hearsay, and incompetent, because the books were not produced. If the books had been produced, it might at once appear that the witness' statement was merely matter of argument; that the books did not in fact show when he first went into the company's employ, but simply contained some entry from which he inferred that fact; for aught we know, the witness might not have seen the books for years, or never seen them at all, but based his statement on what had been told him by others. And yet on this scrap of wholly incompetent testimony we are asked to reject the minute and detailed statements of *Leppens* and *Mrs. Nicholls*, either of whom had more knowledge of this matter in their little finger than *Stockbridge* in his whole body. We must remember, too, that all Stockbridge speaks about is the new car; he says nothing of the prior application of the brake.

But the court below says further, that "*Mrs. Nicholls* differs now herself in giving her deposition from what she stated in the previous case in New York." p. 64.

This is true. and it would be strange if it were not. But the question is, Are these differences essential; are they such as to destroy or weaken our confidence in her testimony? There are two points in which her present testimony differs from her former. She now says that her husband began on his drawing of the brake in the spring of 1846; that he showed it to *Leppens* at that time, and that the car came out with the brake attached in the spring of 1847. On the former trial she is alleged to have said: "I know of my husband drawing a plan of a brake for cars; I should think he drew that plan in the fall of 1846; that was a double brake, as he called it; I know of his going off on a train of cars to try a brake after this; I can 't tell the time. I think it was before March 1847. * * My husband was sick in March, 1847. I think the brake was applied before that; he was sick most of the time till June, 1847; he left home in June, 1847; he had been sick some two months before; he was unwell at the time he invented it. I don't recollect any circumstance that would show the date more certainly; to the best of my recollection it was in 1846, late in the fall; it was quite cold weather; that drawing was made at night, I was fearful of his injuring his health by sitting up at night; he was more unwell after that till he was confined to his house. I am not able to fix the time."

Now first, the principal fact, or the public trial of the brake on a train of cars, is fixed in both her statements at the same date, in the spring of 1847. Second, there is no such discrepancy as to the time of making the drawing as to throw any doubt on either statement. Our theory here is that *Nicholls* conceived the idea and began on his drawings in the spring of 1846; that he had it far enough advanced to show it to his wife and *Leppens* at that time; but that he continued to work on and develop it until it was finally brought to perfection. There is nothing forced or improbable in this theory; on the contrary that is the very way we should expect the thing to be brought about. We thus reconcile both her statements, without doing violence to either.

But again, her testimony on the first trial was very short, and no opportunity seems to have been given her to go into details, and thus refresh her memory, and at the same time prove its correctness; it was in open court, and she was as she herself tells us very much confused and bewildered; whereas in the present case her testimony was taken in chambers, without the noise and hurry and publicity of a jury trial; she had had ample time to think the matter over, and then to give her testimony with that fulness of detail that clearly proves the correctness of her recollection; in short, we think no unprejudiced reader can compare her two statements without being convinced, either that there is no contradiction or else that the last one is correct.

The court below says further,—

> "Besides, she took an account book to *Fields*, and inquired of him as to the time her husband put on the brake; which shows that she really had no memory as to the time."

Is this a fair conclusion? Suppose two judges of this court, for instance, were to be called as witnesses to a matter that happened fifteen years ago, and one of them should go to the other to ask as to his recollection, would it be fair to argue from that that he "really had no memory about it?" Is it not, on the contrary, what every one would naturally do?

We submit then this testimony of *Mrs. Nicholls*, confirmed as it is by that of *Leppens*, as decisive. No one can read that testimony without feeling that the witness is seeking to tell the truth. Her going to *Fields* adds but another proof of this. That she knew when her own child was born, in June, 1847, and that her condition for some months previous must have been connected in her mind with her going out on the piazza to see her husband go by triumphant with his train of cars, controlled for the first time by his now successful invention, so that she could not think of one without remembering the other ever after, seems to us so natural and unavoidable that we wonder any one can be found to doubt it.

Finally, the court will remember how anxious both *Tanner* and *Sayles* were to secure the good will of *Mrs. Nicholls*; how they promised her a handsome present in case that first suit were decided for the plaintiff; and how even after that, and as late as 1856, they still sought to propitate her; pp. 152, 155; 147; 540. But why were they so much interested in *Mrs. Nicholls*, and why did they thus seek to affect her testimony, unless it was because they believed the invention of *Nicholls* to be prior to that of *Batchelder and Thompson?* And we suggest in conclusion, that if the court should find the testimony somewhat conflicting, it should not incline in favor of that party who has used such means to obtain a verdict.

IV. THE CAMDEN AND AMBOY BRAKE, p. 168–635, was the same in all respects as the *Tanner*. We say it was applied on a passenger car on the Camden and Amboy road in 1843, and on a crate or baggage car about the same time. Appellee insists that no double brakes were in use on that road until 1851, when the *Hodge* brake was adopted. The question, then, is one of fact—Was there a double brake on a car on this road as early as 1843, or before 1851?

The car on which this brake was used was one well known as the "Tyler Car," President Tyler having traveled in it on his way to the Bunker Hill monument celebration in 1843. It was distinguished from all other cars on the road by having twelve wheels instead of eight, by its springs, its seats and its superior elegance. The importance of this is manifest. This car being better known than any other, if the defendants' witnesses were mistaken, their mistake could be readily shown. And if a fraud had been intended, this Tyler car never would have been selected, but on the old maxim, "*fraus latet in generalibus,*" the parties would have alleged a use of the brake on a car of the same general style as all the rest. With this single suggestion we pass to the testimony, taking up first the appellant's, and then the appellee's.

1. Edwin Lockwood, p. 168, was master car builder of the C. & A. road for thirty years. He says, "I have made a great many experiments in brakes in various forms; I tried brakes by clamping the wheels on both sides, on four wheel, eight wheel, and twelve wheel cars. I have also tried experiments with brakes by applying a block on the rail between the wheels, etc. We finally adopted a cross-lever brake attached to the body of the car, and the trucks attached to that, in the form shown in the model A. We put the brake on the car from the first of May to June 10, 1843, and the car was put on the road at that time, and conveyed President Tyler on his tour east to the celebration of the Bunker Hill monument. The car was ever after called "John Tyler," by lettering it on both ends inside. We also applied it to a crate car for baggage, which was put on directly after that.

2. Geo. W. Thompson, p. 179. Saw the Tyler car in June, 1843, at the time of the President's tour; it was thought to be the greatest car in the United States; he furnished all the trimmings for it, and did the work himself. While so employed he noticed the brake; it was like model Exhibit A.; his attention was called to it by the men in the shop; the same brake was on the car when he trimmed it again in 1849. "*Lockwood* asked me if I understood about the brakes (I didn't know then that there was any trouble at all.) I told him I recollected distinctly, that the brakes operated from either end of the car, and hung in the center, and that it was the first I had ever seen." He had also seen such a brake on a crate car previous to 1847.

This witness has been mayor of Bordentown six different terms, and also a member of the legislature; his attention had been particularly attracted to the Tyler car because of its elegance, and the President's tour, and also to the brakes. It is not easy to believe him dishonest or mistaken. According to appellee there was no double brake on the road till 1851, but *Thompson* says he saw it on this car in 1843, and again in 1849.

3. N. F. Smith, p. 183, went into the employ of the C. & A. road Dec. 19, 1845, as appears by the books of the company, which he produced, at repairing cars. A few days after he was set to work with one *Vandergrift* to take out the trucks of the Tyler car. He had to go under the car to unhook the brakes before they could get the trucks out, which is not necessary with a single brake. It was a double acting brake, as near like model A as I can recollect; it was the same thing. Sometime after, in the winter of 1845–6, a crate car came in the shop to be repaired with the same brake on as model A. At the time he saw this

brake he asked the men how it was different from the others, that is, the single brake, and they said it was an improvement on the single brake.

The only question here is, could the witness have made so great a mistake as to think he saw this double brake and made these inquiries about it a few days after he went into the Company's employ in 1845, if he really did not see it till six years after, in 1851?

4. L. Cox, p. 187, has been in the employ of the C. & A. road since 1838, as car builder and repairer. In 1847 I saw a double brake on a crate car that came to Amboy; it was connected in the centre by a cross-lever, with a rod running from it to the brake lever, and another rod from the centre lever to each end of the car, attached to an upright shaft on each end of the car, etc. It was like model A, and applied the power to both trucks at once, from either end. I fix the date by the age of my son, who was born Feb. 27, 1847. I was at work on the brake, and was called off to go for the doctor. I had seen such a brake before at the Bordentown shop, on a car afterwards called the John Tyler; she was not named then. I am positive the brake on that crate car could be applied to all the wheels at once from either end. What called my attention to the brake was one of the rods being broken. It was the rod that connects the centre lever to the lever in the truck.

5. Wm. Venable, p. 190; began work for the C. & A. Aug. 28, 1843. June 10, 1843, I saw President Tyler pass through Bordentown on his tour; I recollect of his being in a certain car that was afterwards named "John Tyler." I did not know at that time what kind of brake was on that car. I think in the latter part of 1844 I was called to repair the trucks and brake of that car, and I noticed the cross-lever attached to the body, more particularly because of its being connected with an upright lever attached to the truck; it was necessary therefore to unconnect the rod attached to each lever in one truck, that the trucks might be taken out from under the car. I mean the upright lever in each truck. I disconnected it at each end of the car. I know of the use of this brake on a crate car before 1847. I recollect other double brakes on that road; the *Stevens* and the *Hodge;* to the best of my knowledge and belief they were not tried before 1850.

Here again we ask could the witness confound 1844 with 1851? And if it was 1851 why should all these witnesses have so much to say about the Tyler car, and the crate car alone, when we know that in that year the *Hodge* brake was generally adopted?

6. Charles Yundt, p. 199; was engineer on the C. & A. from 1840 to 1856. Ran excursion trains in 1843, 5 and 6, to South Amboy. In July or August, 1845, his train had to stop, owing to the breaking of a brake rod, two or three miles beyond Hightown. It was a brake like Exhibit A. The bolt came out of the rod attached to the end of the cross-lever, and I had to put another bolt in, and put the rod back in its place. This is the only time a rod fell down in my trains. *William Crim* was brakeman. These excursion trains didn't run after 1846. I was married in 1844, and didn't run any that year, and in 1845 and '6 I run them. I got my clothes all dirty going under the car, and my wife asked me what was the matter when I got home, and I told her.

This has all the marks of truth, and is strongly corroborated by others.

These excursion trains were running in '45 and '46, and they did not run after that, and the Tyler car ran in them.

7. **Wm. Crim**, p. 205; was *Yundt's* brakeman in 1845 and '6, and was with him when the rod fell down, as just shown. The brake was like Exhibit A. It was the rod as the car was going ahead, that fell and dragged on the ground; it made a great rattle and dust. Never knew of the brake rods falling at any other time; they afterwards put up iron straps to prevent their falling in case they broke; in 1845, I think, I know of my own personal knowledge that there was in use on the Tyler Car in '45 or '6, a double acting brake like Exhibit A. They had it on other cars in those years. I could not pretend to say how many. There were two that I know of.

8. **R. C. Walcott**, p. 207; Feb. 26, 1848, took the place of Joseph Cox as engineer on the C. & A. road; Cox having been killed the day before, as proved by his tombstone. He remembers the use of a double acting brake on that line about the time of taking that train; and substantiates it by a minute statement containing all that detail peculiar to this class of witnesses. He also states that this occurred when *Van Rensellaer* was superintendent; which leads appellee to say, in showing up our "contradictions," that "*Van Rensellaer* was called, and he swears he *was not on the road at the time Walcott names*."

But *Van Rensellaer* really says "I was appointed assistant superintendent in '49 or '50, I can't tell which; and continued to act in that capacity till I was appointed superintendent in '55 or '56, I think; *I can't say that either of these are positively correct*."

9. **John H. Jobes**, p. 210; has been brakeman on the N. J. R. & Tr. Co. 32 years. Remembers a double truck car belonging to the Cam. & Am. road, came to Jersey City between '43 and '49 with a double brake on it. The first that called my attention was they said a car had arrived there with a double-acting brake on it; the reason why I took more notice of the brake was that I was a brakeman and had a great deal of breaking to do. I was very anxious to get them put on the car that I was breaking on at the time; the brake, if my recollection serves me right, is what they call a double-acting center-lever brake. If I had not seen the brake from the time I first saw it until the present time, I should have known the brake by the drawing. Exhibit A is the same as near as it can be drawn. I got under the car to see the brake; I had never seen one of the kind, or one work before, and was very anxious to see the movement of the brake.

Being recalled, he says: I know that during *Mr. Talson's* time I was then brakeman on the Newark train; I was transferred to the Philadelphia train. I there found a double-acting brake on a flat car; I mean by a double-acting brake one with a center lever acting upon eight wheels at once; I used that brake on the Philadelphia line; I used it probably two or three years; I can't state the exact length of time. I can't state any further than that it was in *Mr. Talson's* time.

10. **J. S. Gamble**, p. 289; is in the auction and commission business at Newark. Was conductor on the N. J. R. & T. Co. from '37 or '38 to '47 or '48. I think it was '47. As near as I can recollect, a double acting brake was applied some three years before I left the road; as far as my knowledge extends, was on the road when I left; the operation of that brake was different from the one we had formerly used, inasmuch as it broke upon both trucks at once, and from

either end of the car, and upon all the wheels. *John H. Jobes* was our brakeman at that time. I left the road Sept. 1, 1847. There was a lever in the center under the platform car to which this brake was applied, with a rod running to and connecting with the brakes on the trucks at each end, and connected with a windlass at the same time. I know by personal observation how the operation was, by the application of the windlass the brakes bore upon all the wheels of the trucks. This was a platform car; some might have called them crate cars. This was the only brake to which my attention was particularly called; my brakeman, *Mr. Jobes*, called my attention to it, and said it was a very desirable brake, and worked nicely; it was something new. The men spoke of it as a new thing. There is no doubt at all in my mind that there was a double brake on the platform car of that road which operated from either end of the car.

11. George W. Fielder, p. 298; is a produce commission dealer in New York. Went into employ of the N. J. R. & T. Co. in spring of 1845, and left in spring of '48. Remembers hearing a brake talked of among the men when he first went there; it was the *Stanley*, as he recollects; always supposed *Talson* had simplified and got up that brake, which was used on the car spoken of; I don't know this positively. This single center lever brake was on a platform car, and was used, my recollection is, by a man named *Jobes*, a portly man. I havn't seen him since. I couldn't say this double brake was in use on said platform car all the time I was there, but think it was most of the time. I saw it as often as I saw that train come in or go out from the Jersey City depot; how often I could not give any idea. I found this brake on the road when I commenced work there.

This evidence, taken in connection with that of *Gamble* and *Jobes*, is very convincing. *Gamble* left the road Sept. 1, 1847; this brake, therefore, must have been there before that time, and as he swears, as early as 1844. *Jobes* is sure it was in *Talson's* time, and *Talson* left in August, 1849. p. 303.

12. Thomas Herbert, p. 211. Began work for the C. & A. in 1844, at Bordentown; and in July, 1847, was sent to Camden. In 1846, I think, the Tyler car came on there [to Bordentown] and me and my father put a pair of wheels under her. In the latter part of '46 *Mr. Lockwood* took me from repairing to go in the shop, with *Charley Vandergriff*. I went to *Charley*, and told him the boss sent me there to help fix the trucks, and run them under, and let this passenger car down on the trucks. The brake was a double brake, which we put on the car; it had a cross lever in the centre of the car—connected with this lever were four rods, one lever or rod on the right, running to a post at the end of the car on the platform, another one connected with that about four inches back from the rod, etc. It was the same as Exhibit A. There was the same kind of a brake on when I and my father put the pair of wheels under. After I went to Camden in '47 there was one on a crate car, and I think on a passenger car.

The time here is fixed beyond doubt: it was while he was at Bordentown, before he went to Camden. And it is shown by several other witnesses that this *Charley Vandergriff* was repairing cars at Bordentown at that time.

12. B. L. Wolcott, p. 215; was married April 13, 1845; a few weeks after began firing for Yundt, and fired for him 11 months, partly on these excursion trains. In going down the cut two miles this side of S Amboy, the engineer went to reverse his engine, and something broke, so that he lost con-

trol. There was a man on the engine with us, by the name of *Wm. Sharp;* he and I went over the top of the cars to put the breaks on. I went right to this Tyler car first, and put the break on. My reason for going there was because it had a double brake. The double brake held on both trucks, and all the other cars between had only one brake, that held on one truck only. That brake was like Exhibit A, as near as I could explain it, and is in use now on the C. & A. road. I had noticed the brake on the Tyler car before, when they took President Tyler over the road. August 3d, 1844, my father died; the night before I slept in the Tyler Car, which I had been cleaning. I know there were double brakes on it then. We were all in danger of our lives at the time the engine gave out, and I think I have not been through that cut three times since without thinking about it. I stopped firing early in 1848. I was firing for *Joseph Cox* when he was killed. There was a crate car in the train with double brakes. I had to drill the train; [that is, get the train into place after discharging the passengers.] I used to cut this crate car loose and let it down into the pit pretty much every day, to save time.

This *Joseph Cox* was killed Feb. 25, 1848, as proved by *R. C. Wolcott*, who took the date from his tombstone, p. 208. Now, taking all this together, it seems impossible to explain it on any other theory than its truth. Appellee has shown the great importance he attached to it by the length of the cross-examination, in which he has sought to show that the witness was mistaken as to the time and place; but has only succeeded in proving still more clearly the fullness and accuracy of the witness' recollection. Failing in this plaintiff next sought to show that the Tyler car could not have been in an excursion train in 1845.

"But another of defendant's witnesses, Head," says the plaintiff, "swears that from and including 1845, and for four years afterwards, he was depot master at Tacony, and had the "Tyler" car under his charge there all the time, and he names the trains she ran in during those years, and proves conclusively that during the whole period she ran in only two kinds of trains, mail trains *running to Jersey City*, and the '*Trenton way train,*' *not going beyond Trenton*; while *Wolcott* says the circumstance he referred to occurred near *Amboy*, which is a *terminus* of the Camden and Amboy road, more than forty *miles* from Trenton, and across the Raritan Bay from Jersey City, which is on the *New Jersey* road, and not on the Camden and Amboy at all."

To this it might well be said that *Head*, being at the depot, could not possibly know all the trains the Tyler car ran in; and again, that he is careful to say, when first asked, that those were all the trains he knew about; though he afterwards goes a little farther, and says it only ran on the mail and way trains as long as he had charge of it.

But this is of slight importance, for there are no less than *ten* other witnesses who confirm *Wolcott*, and more than half of them are the plaintiffs' own.

Jeffries says excursion trains ran on the C. & A. about '45 and '46, or '46 and '47, and the Tyler car ran in them most of the time. p. 409, 410.

Ward says it was an extra car for a while to run on special occasions. Int. 19, p. 427.

Condit says it ran on the Philadelphia trains between '43 and '51, but not regularly as the other cars. p. 439.

Van Syckel says it ran in his train daily from Trenton to New York; sometimes from Camben to Amboy. This was between '41 and '46. p. 506, 507.

J. Herbert says it generally ran to Trenton after Tyler made his trip; sometimes on excursion trains, sometimes on others. These excursion trains were running in 1845. p. 564, 5.

Quigley says these excursion trains ran in '44 and '45, on the Camden and Amboy, and that the Tyler car often ran in his trains between '43 and '51. p. 480, 484.

These are all plaintiffs' witnesses. Then for appellant *Cox* says that he saw the Tyler car at Amboy from '45 to '50, though not very often. X. 32; p. 189,

Yundt says the excursion trains ran in '45 and '46 from Philadelphia to S. Amboy, and the Tyler car sometimes ran in them. X. 72; p. 204.

Crim was *Yundt's* brakeman in '45 and '46, and speaks of these same excursion trains. p. 206.

A. Heath was conductor in these excursion trains; they ran in '43 and '45, and the Tyler car ran in them. p. 270.

This second attempt to get over the testimony of Walcott has thus turned out even worse than the first; not for want of sufficient ingenuity and boldness on the part of complainant, but because that testimony was true.

14. GEORGE STOCKHAM, p. 227; entered employ of the C. & A. in 1843. Went into the paint shop of an errand in winter of '44, or spring of '45, when *Charley Vandergriff* called my attention to the double brake. I got in under the car where he was at work, and saw the cross lever; and lever on each truck, and four connecting rods. It was like the brake in Exhibit A. The way I fix the date, there was a gentleman wanted me to come out to Downingtown, Penn., and work for him that spring, 1845. That is all I know about it. This was right away after I saw this brake. I was on my way to New York, and I met him in the cars, and I havn't been to New York since, to the best of my knowledge, till last Friday.

15. THOMAS W. DUNN, p. 230. Foreman of the car trimming department of the C. & A.; since October, '44. Re-trimmed the Tyler car in the winter of '44–'5. It had six wheel trucks, with a brake on both trucks, that could be applied from either end of the car. My attention was called to it by seeing a man by the name of *Charley Vandergriff*, who was working at the repairs, and who got upon the platform and applied the brakes to see if they worked right. He first tried them on one end, then passed through to the other end and applied them there also. It applied the power to both trucks at the same time. I went in and out of the car several times that day. Had never seen any one get upon the platform and try the brakes before. I examined the construction of the brakes.

16. JOHN CONOVER, p. 233. Began to work for the C. & A. in 1839. I recollect the President getting on the train at Camden. I know it was in 1843. The car he went in was a car lately done up, and had these double acting brakes.

That I know positively, because I was under the car, looked at them, and examined them, and got a man to work them for me while I was under the car to see how they worked. I have frequently worked them myself when we were drilling the cars. I set switches and got on the car and used the brake myself, and saw that it worked on both trucks at either end of the car at once. The plan is the same as on Exhibit A. The car was named the Tyler car after the President went in it, and continued to have this brake on it.

Better testimony than this it would be hard to find. Here is a witness presumably honest, certainly intelligent, who knows just what he is saying, and with the best means of knowing whether it is true. One such witness is worth ten who simply swear that they never saw such a brake till 1851.

17. **JOSEPH HEAD**, p. 234. Went on to the C. & A. road March 21, 1845, as superintendent of the Bristol depot; stayed there till '47, then went to Tacony. I knew of a double brake on the Tyler car. I found it there (at Bristol) when I went there; it was a brake with a lever and four rods, which would pick up both trucks at once; it was like Exhibit A. What called my attention to it was, it was the only car that had that brake on at the depot; the others had the old-fashioned lever brake, to take up one truck at a time—one at each end. The next brake like that I saw was under a flat car for carrying baggage crates on the mail line; that was in the latter end of 1845; it was there that winter, before I left to go to Camden.

Here is another witness whose testimony it seems impossible to doubt. The time of his going to Bristol is fixed beyond question by the letter containing his appointment, which he still had in his possession.

18. **JOSEPH REED**, p. 236. Was brakeman on the C. & A. from May 1, 1850, to near the end of 1851. There were double acting brakes on the road in 1850. They had a lever in the middle of the car. It was on the Tyler car, and on the crate car, and on Nos. 9 and 10, passenger cars, that run in the train that I was brakeman. They had four rods, and they broke on each end of the car; the brake on either end would work on both trucks; it was the same as Exhibit A.

This only goes back to 1850, but is directly opposed to the theory of appellee, which is that there were no double brakes on the C. & A. till '51; and then they were not the *Tanner*, but the *Hodge*. This witness was brakeman only for those two years, '50 and '51, and cannot well be mistaken as to the time.

19. **JOSEPH HAGAR**, p. 238. Was brakeman on the C. & A. from peach time in '48, till peaches were done in September of that year. He used to drill out the cars in the morning; and one morning he was looking at the brake on the Tyler car, and saw it was a double brake. He told his engineer, *Joseph Trout*, he would like to have it on his car because it was double. *Trout* said he wished they could, it worked so much better. They got under the car and looked to see how it was rigged; it had a lever in the center and four rods attached, and you could get on either end and put on all four brakes at once. It was like Exhibit A. Saw the car often after that at Trenton, Bordentown and Amboy.

There can be no mistake here as to the time. The witness was married March 23, 1848, and in that way fixes the date when he began. He was on that train only that one season, and then went on a dirt train, thus fixing the date when he left.

20. Wm. Coulter, p. 240. Has been conductor on the C. & A. since Oct. 8, 1845. In the fall of '45, or spring of '46, he was applying the brake on the Tyler car and found it did not hold. I let go, and some one was applying it on the other end, and I knew nothing about it. When he let go, the handle I had hold of flew back and hit me on the hand. I found out afterwards that it was being applied on the other end. There is not the least doubt in my mind that this took place before 1847.

Being recalled, he says he now knows this occurred in the fall of 1846, while he was running the Philadelphia train in the absence of Gamble, the regular conductor, who was engaged in Philadelphia as witness in a lawsuit, and he produces a letter dated Nov. 17, 1846, which he received while running that train. He also says that this flying back of the crank took place on the morning train at Campbell's Station. We were about making a stop there, and I was on the rear platform of the Tyler car; I thought he was going to run by, and I attempted to put the brake on; so I took hold of the crank and took the slack or chain up as far as it would go, and I didn't think it was holding any, so I let go of it and, after the cars had stopped, I was standing on the platform, and when the crank revolved it hit me on the back of the hand, and it hurt me so that I felt it for a week or ten days. p. 340.

The first I ever ran on a Philadelphia train was during that week I was hit with that crank, and that week I received that letter, and after that I went back to my regular train. p. 342. Has experimented within the last two weeks, he supposes ten times, to see if any brakes on their road would operate in the same manner, and found none of them would except those on the same principle as the center lever brake. p. 342.

As it seems to us there is no way to get over this. It will not do to charge the witness with swearing falsely, for every word goes to prove his honesty. Neither can there be any mistake as to the time, for there is here documentary evidence to show the very week when he was running the Philadelphia train. And finally, there is no brake with which the facts stated could occur except this very brake that our witnesses all swear was on the Tyler car, viz., the *Tanner* brake.

The plaintiff made a desperate effort to overthrow this testimony, not to prove it false, but to show that the same thing might happen with the *single* brake. This is his argument in the court below.

"Coulter said that at the time referred to, he attempted to apply the brake at one end of the "Tyler" car, and found he could not move it, but in a moment the windlass handle flew round, and hit his hand violently, and he soon after learned that a brakeman had just been applying the brake at the other end of the car. From this defendants strove pertinaciously to show that there *must have been* a connection between the brakes at the two ends of the car, and they called numerous witnesses to state that such a circumstance *could only occur with the Tanner form of double brake.* Seeing so much effort by defendant's, complainant examined a few witnesses—Waterman and others—who proved conclusively that the same thing frequently happens with the *single brake*—though I shall not dwell upon what they say, for the matter is too insignificant—and then called Coulter himself who disposed of the subject most completely, as follows: "that is, by saying that it would be impossible for him to tell from this flying round of the crank, whether it was a double or single brake.""

It would be hard to crowd more errors into the same compass. In the first place *Coulter* does not say that he "could not *move*" the brake; on the contrary he says he did move it, that he wound it up, and found it did not hold, and so he let go; and afterwards the crank flew round, and hit his hand. If it had been true that *Coulter* could not "*move*" the brake, we should have to conclude that it was already wound up, as appellee's theory requires. But he did move it; he took up all the slack, but found it was not holding any; that is, he encountered no resistance; why? because it was already wound tight up at the other end, and the pressure at his end was all taken off This is precisely what would happen with the *Tanner* brake, and what could not happen with the single brake.

Appellee has taken great pains to prove that the single brake will fly back when loosed; there was no need of that, for everybody knew it before; but that has nothing to do with this question.

Waterman says nothing about winding up a single brake, and getting no pressure on it, and then having it fly back. Appellee took good care not to ask him that.

In the second place, and what is yet more material, appellee overlooks the fact that this flying round of the crank *set the witnesses to inquiring into the cause of it*.

Coulter did this and found that there was a man at the other end. He also experimented, and found that no other brake would act in the same way besides the *Tanner*.

J. C. Hillman, who got hit in the same way, went further; he not only found out that there was a boy at the other end, but they got under the car and found that there was a double brake. p. 249.

Even appellee will not pretend that this ever happened with the single brake; or that any one ever looked at a single brake, and found it double.

Again, J. H. Hillman, another witness who had noticed this flying round of the crank, says that when he took hold of the crank he *felt another person drawing the brake at the other end of the car*, p. 243, a thing peculiar to the double brake alone, and which appellee has made no attempt to prove ever would happen with the single brake. And *Jeffries*, one of appellee's own witnesses, says that he found out that there was a double brake on his car in the same way. p 410, 411.

Finally, plaintiff proclaims that *Coulter* has settled the whole thing by admitting that he could not tell from what happened to him whether it was a double or single brake.

But appellant did not offer *Coulter* as an expert or philosopher, but simply to tell the facts. Any one can prove a fact, though it may take a philosopher to explain it. We all know that water can be raised in a pump, but not every one can give the reason, or make the proper deduction from it. Apples fell, and the law of gravitation existed long before Newton, but he was the first to deduce the one from the other.

21. **John H. Hillman**, p. 242, says President Tyler passed through Trenton June 10, 1843; and fixes this date by producing a newspaper published at that time. In May, 1848, I was asked to help put on the brakes by the conductor. I took hold of the crank of the brake and felt another person drawing the brake at the other end of the car; or, in other words, the brakes were put on from the other end, and I noticed when the train started and the brakes came off, that the crank I had hold of flew round of itself. p. 243.

Now all this would happen with the *Tanner* brake, and it could not happen with any other. He could not have felt another man applying the brake at the other end with the single brake.

22. **James Seeds**, p. 244, was brakeman on the C. & A. 4 or 5 years ending in '46 or '7. The first he recollects of a double brake was on the Tyler car, when it first came on Quinton's line, or the way line from Philadelphia to Trenton, about 1844. About '45 or '46, it was put on a crate car; there being only one brakeman on the line it was put there to have more effect upon the wheels than a single brake could have; on that connected brake I could check 8 pair of wheels; I mean 4 pair, two front and two back. I have seen the wheels in both trucks slide when this brake was applied. I was brakeman in this train. I recollect positively that the Tyler car had a double brake in 1844, from using it daily whenever it was on our line. Mr. Lockwood asked me if I recollected the Tyler car, and I told him I did; if I recollected what kind of a brake, and I told him a double connected brake.

23. **Joseph Capner**, p. 247; was brakeman on the C. &. A. six months, beginning Aug. 3, 1847. He always looked after his own brake. In 1847 he knew the Tyler car very well, and there was a connected or double brake, with a cross lever under the car, with four rods and a crank on both ends; and when the brake was applied from one end, it applied to both trucks. It was like Exhibit A. About a year and a half after, it may be longer, I knew of a brake on the C. & A. with two cross levers. I never knew what they called it.

24. **J. C. Hillman**, p. 249; knows of double brakes on the C. & A. in 1845. He was 14 Aug. 10, 1845, and had his choice either to go to school or go to work at the end of his August vacation, and chose to go to work. It was before this he saw the Tyler car; he and several other boys made a practice of being round the railroad when out of school. He heard the new engine (the "Ben. Franklin,") and the Tyler car, were at the old depot in Trenton, and at the lower tank; we got round the car, went inside, and looked at it, came out and commenced fooling with the brakes, and while twisting them on and off at each end, I was hit in the side by the brake handle; my inquiry then was, who done it, and what done it, and the boy on the other end told me he pulled the brake out of my hand. I couldn't see how that could be, because it was different from any brake I ever saw on a car. We then got down and looked at it underneath, and we found that by putting the brake on at either end we put the brakes on all the wheels.

If this evidence is not true, there is no use in ever trying to prove anything. If there is anything a boy remembers, it is when he stops going to school and begins to work. Again, the witness speaks of the new engine, "Ben. Franklin," as being there with the Tyler car. He mentions it incidentally, and without any thought of its bearing upon the case. But it turns out that the "Ben. Franklin" was a new engine in '44 or '45, as shown by *Hutton*, one of plaintiff's witnesses, when re-called by defendants, p. 334. This fixes the time, even supposing there had been any doubt about it, beyond all question.

Then as to the brake, the witness had his attention called to it just as *Coulter* and *J. H. Hillman* had, by receiving a blow from the crank. This set him to investigating the character of the brake, when he found, on getting under the car that it was a double brake. Only two answers can be made to this—either that the witness invented the whole story, or that it did not happen till 1851, when he was 20 instead of 14.

25. ASHER PANCOAST, p. 250; was extra brakeman on the train that took President Tyler to Camden. The afternoon before they started, he and *John Banney* were standing by the side of the car which conveyed the President. *Benj. H. Harber* and *Charles Vandergriff* were at work on the under gearing; *Banney* said to me that I must ride behind the President; *Harber* said there was no use of more than one riding behind on that brake, for one man was as good as two; we got into a little kind of contradiction there; he told us to get upon the car and try it, which we did; we found it was as he said; one was on each end of the car, and we both put the brake on and found *Harber* was right. In the meantime *Captain Shipman*, the Superintendent, came along; he says, "There, you are talking again, as usual; more talk than work. I wish you would work more and talk less." The brake was connected with a rod from the center of the truck with a bolt and key to a cross bar. This cross bar applied the power to both trucks. Exhibit A represents the brake as near as I can recollect; but I cannot recollect exactly. I know of my own knowledge there was a double brake on that car. I was passenger in 1845 on an excursion train; something got wrong under the train; we stopped, and the brake rod was down dragging on the ground. The engineer came to see what was the matter, and went to the engine and got his tools and bolt and put the rod up. This rod was attached to the cross lever. *Charles Yundt* was engineer; *John Holland* fireman; *Andrew Heath* conductor; *William Crim* and *Joseph Harber* brakemen.

In 1844 there was a baggage car made for the 5 o'clock mail line from Philadelphia to New York. They put eight wheels under that, and that had a cross-lever brake on. I was not brakeman after January, 1845.

This has all the ear-marks of truth. No man could have invented all these details. If his story is not true, this witness must bear away the palm for ingenious falsehood.

26. H. H. DISBROW, p. 256; went to work for the C. & A. in 1845, on the road; in '47 went into the shop, repairing cars and brakes. In '48 had to repair a brake that worked from the center of the car, on both trucks at once; one of the rods connecting with the cross lever was broken, and he had to take it down, and take it to the blacksmith's shop, have it mended and take it back again. His wife was confined at the time, and his oldest son came after him, and he went for the doctor. She had a boy, born March 15, 1848. This is the only means I have of fixing the date, and the trouble I had in fixing the brake; being a new hand in the shop. I only recollect this one car where one of the rods connecting with the cross lever was broken.

27. CHARLES COX, p. 261; took an engine on the C. & A. in February,

'48, the one that *Colt. Whitman* ran; he had taken the one *Joseph Cox* had run; *Cox* having been killed. I lost a child that year, which fixes it in my mind. I ran to meet every mail train, and I would wait there on the turn-out, till the train arrived. While standing there I saw the brake applied, and the wheels on both trucks slipping. I saw that scores of times during the years I was running there. It was on a flat crate car. I left there in the spring of '49. The brakes were applied by one brakeman only, both trucks sliding; there was only one brakeman to a train at that time. I will swear positively I saw the wheels slip on both trucks. I saw them slip every time the train passed. What drew my attention was the fire flying from under the truck.

The time here is fixed in several ways. The death of the witness' child ought be sufficient, but there is stronger evidence. It has already been shown that *Joseph Cox* was killed Feb. 25, 1848; and it was his death that gave witness his situation on this train. He left that train in 1849, after having run it a little over a year. The proof is equally clear as to the brake. There was but one brakeman to a train all that year; witness saw him apply the brakes, and the wheels slip in both trucks. He saw this not once only, but scores of times. He was standing there waiting for this train, and with nothing else to do.

The plaintiff's answer to this is, if possible, even a greater failure than his answer to *Coulter*. Like that, too, it is an answer made in showing defendant's "contradictions and absurdities."

"As your Honor knows, one of the most useful features about a *double acting* brake is that it *prevents* the wheels from slipping! But aside from this inherent contradiction, the witness proves the falsity of his story by saying that he knew the wheels slipped *because he saw the fire fly;* and then, when asked on cross-examination *what time of day* it was, he says it was *in the middle of the forenoon*—quite too light, if the court please, to see fire fly from car wheels."

We have here two most remarkable assertions; that double brakes *prevent* wheels from slipping; and that fire cannot be seen to fly from wheels in the day time. The first is flatly opposed to the record, the second is flatly opposed to our common experience.

The evidence as to wheels slipping with this double brake is very full. *Seeds* says that he has seen the wheels in both trucks slide under this connected brake, both when applied by himself and when by others. Int. 6, p. 244.

Bogy says that he saw the brakeman put on the brake on this Tyler car, and he saw the wheels slide in both trucks. Ints. 3, 4, p. 266, 7.

These however are appellants' witnesses. But the same fact is proved yet more fully by appellee's.

Ragland says that as the *Stevens* brake is ordinarily arranged the wheels do sometimes slip. p. 858.

Jackman says the wheels often slip with the double brake. p. 890.

Renwick, appellee's expert, says that in all brakes he has ever seen the brakeman can slide the wheels. p. 940. And he shows very clearly why this is so with the *Tanner*, viz., because with the increased leverage a greater pressure can be brought to bear. p. 940, 942.

Watts says that he has known the wheels slide with the *Tanner*, and with the *Hodge*. *I have seen them slide repeatedly coming into stations. It is a very common thing to see them slide.* p. 796–7.

Stull says he has seen one pair of wheels slide, or two pair, or all, with the *Tanner*, the *Stevens* and the *Hodge*. p. 804–5.

Weightman gives the result of certain experiments with the *Tanner* brake on the Long Island road, where the wheels seem to have done nothing else but slide. p. 808–9.

Doane was present and tells the same story. p. 813–14. He also says that he has seen wheels sliding with the *Hodge* brake when coming into a station, sometimes a part of the wheels only, sometimes all. p. 821; and finally *Kraft* says he slid all the wheels with the *Tanner* brake, and he has noticed the same thing with the *Hodge*, when coming into a station. p. 819.

As to seeing fire fly in the day time, any one who has ever been in a blacksmith shop, or struck sparks from steel, or watched the revolutions of an emery wheel, knows that there is no difficulty about that. The sparks thrown off from wheels are of the most intense heat and brightness; as *Renwick* says, "the particles are so intensely hot as to burn in the atmosphere, or in other words they are heated to a high white heat." p. 941.

28. **Wm. Disbrow**, p. 264; went on to the C. & A. June 11, 1847, as fireman. In the fall or fore part of the winter began firing on the Amboy line. In the winter of 1847, at the end of our route, near Camden, one of the cars was thrown from the track; it was a flat baggage car. I was sent under this car to disconnect the brake; it had a cross lever in the center of the car, with four rods from it. I disconnected all the rods from the cross lever. Exhibit A represents the brake. This happened the first day I fired on that line. I fired on that line, I think, only to the end of '47. I am not positive.

Here we have both the date and the brake clearly proved. It was the very first day he ran on the Amboy line; it was a flat baggage car that was thrown off; after that event he went on a dirt train, where there were no baggage cars.

29. **Patrick Bogy**, p. 266; went on the C. & A. July 4, 1843, as brakeman on a freight train, with passenger car attached; was brakeman about five years; then conductor on freight train. While brakeman I saw the brake on the Tyler car, and on a flat baggage car. I have been in Camden, and saw the mail train go in and out there every day; and saw the brakeman put on the brake on the Tyler car, and the wheels slide in both trucks. By hearing others talk of the brake I made it my business to go and look under the car, and see how the brake was connected, and found it connected by a lever under the center of the car. When the man took hold the crank at one end it applied the brake to both trucks, and made the wheels slide under both trucks. I observed this brake along in '44 and '5. Saw it first in '44; had heard men talking about it, and it made me more anxious to see the

car, particularly to see how the brake was rigged. A few days after I was taken sick, intermittent bilious fever, and had a doctor's bill to pay; his bill was dated October, 1844. I heard the engineer say that when the brakeman applied the brake on the Tyler car, he felt the engine jerk. I heard them remark that it was such a good brake that, if we had more of them, they would not have so much trouble.

30. R. C. BUZBY, p. 270, is time keeper on the C. & A. road. Knows of the Tyler car before it left the shop, to take the President over the road; it had a brake which worked from each platform; it had just come from the Philadelphia & Trenton road, and was fitted up in our shop. It was different from anything we had before, made me notice it; different springs, spiral and elliptic. I took notice of the brake, and looked underneath to see why, by turning one crank at one end, it would put the brakes on both trucks. I found it was by a cross lever, fastened under the bottom of the car.

Now we ask in what can this witness be mistaken? Certainly not in the time; it was before President Tyler had been over the road, before the Tyler car had begun to run, that he saw this double brake. He examined the brake particularly, to see how it was that all the brakes were applied at once.

31. ALFRED HURD, p. 347; went on the N. J. R. & T. Co., as engineer, about 1840, and left about 1850. I know of a brake on a car of that road termed a double brake. I couldn't say exactly when I first saw it; it was in the administration of *Joseph F. Talson.* It acted on both trucks, instead of one, from either end of the car. I am sure I saw the brake during *Talson's* administration. What took my attention was no more than I saw one man could apply the brakes to both trucks, and it would answer the place of two men. It was a passenger car; what train it run on, or where it run, I could not tell.

Talson left the New Jersey road in August, 1849, p. 303.

32. ISAAC DRIPPS, p. 366. was superintendent of machinery for the Cam. & Am. road from 1831 to 1852 or '3; is now master machinist on the Pitts. Ft. W. & Chi. Road. The first I saw of double brakes, that is, brakes that would apply to both trucks, was on a car that was rebuilt by the company's shop at Bordentown, called the John Tyler car; the year I can't tell you. I can only fix the date in this way—when Pres. Tyler first crossed the road, after being inaugurated, he rode in that car, and the car was called the "Tyler Car" afterwards. There was a double acting brake on the car at the time it took him over the road; the brake was applied by a brake-shaft at the end of the car; of course, as they wound up the shaft, it applied the brake blocks against the wheels of the trucks, the four outside wheels of each truck, the trucks being six wheeled. I cannot state any particular time that I examined the brakes; but as the car was in the shop being rebuilt, I of course saw all the work put on it as the work progressed. I cannot specify any particular time; I suppose I saw it in the shop every working day. I distinctly remember when the car was finished; the general plan of the brake; that the brake blocks were applied to the wheels of both trucks, but I cannot recollect the arrangement of the details of levers, rods and blocks. I distinctly remember that I saw the brakes at the time the car was finished.

The car, when first rebuilt, was a very prominent car to us railroad people; we had put on it all the improvements that we had made up to that time.

This is our evidence, and, if it is not true, we think the court will agree with us that this is one of the most extraordinary cases of wholesale perjury ever known. We have here over thirty witnesses, not one of whom had any interest in the suit, and most of whose testimony is of such a character that it is impossible to account for it on any other theory than wilful perjury, or, as we think, even on that. We would here ask the attention of the court to the following suggestions:

First. How happened it that all these witnesses agreed to place this double brake upon these two cars, the Tyler car and the crate car? This is the central fact in their whole testimony; and one that certainly requires explanation. And until it is explained we submit that this alone is sufficient to make out our case. Such a coincidence, though simple enough if the testimony is true, is little less than a miracle if that testimony is false.

Second. These witnesses, though nearly all starting out with this central fact, do not stop there, but add to it the greatest variety of incidents, showing how and when and where their attention was first called to this double brake; incidents that they could never have invented for themselves, and which it is scarcely possible any one else should have invented for them. *Charles Cox*, *B. L. Wolcott* and *J. C. Hillman* afford a marked illustration of this, though there are many others nearly as striking, and hardly one but what has more or less of the same thing.

Third. In the midst of all this diversity these witnesses yet preserve the most remarkable unity and harmony, as to all those matters upon which any two or more of them happen to testify. Many of these matters tend directly to prove the main fact at issue, while others derive their sole importance from the casual and therefore all the more valuable confirmation they lend to the witnesses.

Fourth. This evidence is positive, and not negative. It is direct, and not argumentative. The witnesses swear to what they saw, not to what they did not see; to what they themselves knew, not to what was told them by others. Most of them actually saw the brake; they handled and worked it; they examined carefully into its construction and operation—they all had some special and sufficient reason for knowing that it was a double brake.

Fifth. As to the time, the question here is neither nice nor difficult. It is not a question of a month or a week, but of years. According to appellee, there was no double brake on the Camden and Amboy road before 1851 or '2, and then it was the *Hodge*. The *Tanner* was not introduced till 1854. But we say it was on the Tyler car as early as 1843; and many of our witnesses carry it back to that date. Others did not see it so soon, either because they were not on the road, or did not have their attention called to it. But all put it much earlier than 1854. To suppose that any of them could have made so great a mistake as to put '43 for '54, or even for '51, is out of the question.

The evidence is assailed in various ways. First, it is alleged, as to some of our witnesses, who have fixed the date by marriages, births or deaths, that "there is no connection between such events and the use of a double brake; and that the effort so to fix the date is almost invariably a sign of a *corrupt* or utterly ignorant witness."

But this sort of memory is recognized by every standard writer on the subject as of all the most universal. It is the memory of the unlearned, of men who have not been trained in the severer methods of the schools; of the Indian, the trapper, the backwoodsman; of many women, and of children; in short, of all ages and classes of the uneducated everywhere. It is the memory dependent on propinquity of time and place. Or, as Dugald Stuart expresses it, "The bulk of mankind associate their ideas chiefly according to their most obvious relations, those, for example, of resemblance and analogy, *and above all, according to the casual relations arising from contiguity in time and place.*"

This memory, though unscientific and in one sense illogical, is nevertheless the strongest and most reliable, especially for retaining what might seem to others wholly isolated facts. It is almost the only way indeed in which such facts can be remembered. For as they are not parts of any harmonious whole, and are of no use either to reason or philosophy, they must generally be remembered in this way, or not at all. Of course we do not pretend that this memory, more than any other, is absolutely incapable of error. Those who depend upon it are liable to err the same as others, but the fact that they do rely upon it throws no imputation on their honesty or intelligence, whatever it may prove as to their mental habits and training.

Appellee next advances a theory, by which he seeks to account for so many witnesses swearing as they have done, without impeaching their honesty. He says that the record is full of proof that in 1843 and long after, it was common to fit the passenger cars of the C. & A. and N. J. roads with two single brakes, one at each end; that these were called double brakes, and the witnesses have confounded them with double connected brakes." And he adds that some of the witnesses "speak of knowing that double brakes were in use on the C. & A. road *by their seeing the brakes applied to all the wheels.* See, for example, testimony of Charles Cox."

But this theory is not supported by the fact. Very few, I think only two, of the witnesses speak of two single brakes as a double brake. And as to Cox, instead of saying what is above imputed to him, he says he knew they were double brakes because they were applied to all the wheels *by one brakeman*, which is an entirely different thing.

But this is unimportant. For this theory, even if true, wholly fails to meet the case. In the first place, if double brakes were so common in 1843, how happens it that the witnesses speak only of the Tyler car and the crate car? In the second place, they do not speak simply of *double* brakes, but they say *double connected* brakes—they saw the cross lever, and the four rods—they had to disconnect them to get out the trucks—they got under the car, and examined them

—they got another man to work them—they found that a man at one end broke on both trucks; they ran over the tops of the cars to get to the Tyler car in a dangerous emergency, because it had this double brake—in short, there is scarcely a word in this whole testimony that does not give this theory the lie.

Finally, as the appellee will have it, this whole scheme was got up by Talson & Lockwood, and by them forced upon the other witnesses. Talson, a man of the highest respectability, is never spoken of but as "this fellow Talson;" while Lockwood, without the slightest foundation, is pronounced a "shrewd rascal," and charged with having deliberately "made up his mind to adopt some prominent incident, like the President's journey, as the starting point for his fiction." Whether he also invented the stories told by Charles Cox and B. L. Wolcott, J. C. Hillman, Coulter, Jobes, Gamble and Head, and all the rest of them, we are not informed.

Having thus presented our side of the question, let us see what is brought against it.

The appellee has here three sets of witnesses—first, those who were on the Camden & Amboy road, or saw its cars, and say there were no double brakes till 1851. We give such portions of their testimony as we deem material, leaving it to him to supply deficiencies, if any.

1. J. E. HUTTON, p. 387, says that the Tyler car, when it first came out, had a single brake, and until 1851; and the double brake as long as he knew it afterwards; that he noticed it particularly after it got a double brake.

This sounds well, but will not stand examination. *Hutton* was not on the Camden & Amboy road; he was an engineer for the New Jersey road, and *thinks* he had the Tyler car in his train prior to 1850. He does not tell us how he knew it had single brakes; that he ever examined the brakes or operated them, or saw them, or had anything to do with them in any way.

2. EDGAR MORRIS, p. 390, says he saw the Tyler car about twice a week from '43 to '49; that, *to the best of his knowledge*, it had a single brake; that it could not have had a double brake for any length of time without his seeing or hearing of it: that he was led to observe the kind of brake on the Tyler car by the inspection of cars, looking under them frequently.

But after all this, he says he cannot tell, *of his own knowledge*, what kind of brakes were on the Tyler car from '43 to '49; that he had no practical knowledge of double brakes; he never inspected any cars, he was not in the employ of the C. & A., but in the repair shop of the N. J. road; he doesn't know whether he or the men in his shop ever did any repairs on the Philadelphia cars, but *thinks* they did.

3. GEORGE BROWN, p. 396, went on the New Jersey road in July, 1850. Saw Camden & Amboy cars come into Jersey City; *not a great many.* They used to do the light repairs on those cars. If there was anything wrong with the trucks the C. & A. men attended to that. *Thinks* they had no double brakes before '51; *thinks* he should have known it. He used to go under these C. & A. cars—but he does not say he ever did this before 1851.

4. D. H. **Baker**, p. 403, never saw any double brakes on the C. & A. cars that came into Jersey City from Sept. '49 to Sept. '51; *thinks* they could not have had any without his knowing it. They did all slight repairs on these cars.

But Baker was not in the employ of the C. & A., he was master car-builder of the N. J. road; of course he never himself did any of these slight repairs on the C. & A. cars.

5. S. H. **Brown**, p. 407, *thinks* that one Cummings built four or five cars for the C. & A. road between '49, and '52 or '53, with single brakes; the argument being that no road would buy any more single brakes after they got the double.

But the double brake was well-known on the C. & A. road in 1851, as the plaintiff himself asserts. This argument therefore proves too much.

6. D. T. **Jeffries**, p. 409, used to go on excursion trains in 1845 and '6, or '46 and '47; twice a week during the season to assist the conductor. The Tyler car was in these trains and had a single brake.

But the question is, how did he know? How came this boy of 17, who went to assist the conductor, to examine so carefully into the construction of the brakes on this particular car? For the court will notice that it is not an easy thing to see. That is, no one could see whether the brake was single or double without stooping down and looking under the car. Nor would he be at all likely to see it then, unless he had been told beforehand that there was something peculiar about the brakes. The *Tanner* brake is the same in the trucks as the old single brake; it is nothing but two single brakes united by the centre lever, and its two short rods. Any one, therefore, who was not thoroughly acquainted with the brake, might look under the car a hundred times without seeing that the brakes were double.

This suggestion applies not only to this witness, but to nearly all the witnesses for the appellee. Unless they had a special reason for examining the brakes on the Tyler car, they would be very apt not to notice any difference between its brakes and the single brake. And as a rule they had no such reason. In other words, there was no reason why they should know whether the brakes on the Tyler car were single or double. But this boy says he used to examine the Tyler car almost every time he came where it was, about twice a week, while on these excursion trains, and once or twice a week while on the way to Tacony, up to the fall of 1849. He was led to do so from its being a much easier riding car than any other; all the men, when they met together, would talk about it, and we would get together and look at the gear, the springs and construction of the car, that we might observe what new improvements were being made.

Yet after all these examinations, he is unable to describe any of the peculiarities of the car; and afterwards, when he does attempt it, says that *it had four wheeled trucks, when the most noticeable thing about it was that it had six wheels*, and that it had spiral springs, when it had both spiral and elliptic. And finally, he says, int. 21, that in 1851 or '2 he went to apply the brake, and found most of the pressure taken off by a man at the other end, and on looking found that it was the *Hodge* brake, whereas the pressure is thus taken off only by the *Tanner* brake, and is rather increased by the *Hodge*, as the court can readily see by the models.

7. ERASTUS REID, p. 416, was on the New Jersey road from '36 to '49, in the repair shop. About 10 Cam. & Am. cars came to Jersey City daily; they had single trucks. He never repaired or inspected them himself, because that was other men's business.

8. AMBROSE WARD, p. 425, was in the repair shop of the New Jersey road from 1842 to 1850, and used to repair cars of the Cam. & Am. road; only light repairs. They had single brakes until about 1850. His duties did not specially require him to know what kind of brakes they had. Remembers a car that had a water closet on the platform; noticed it particularly because it was so novel. I saw it a great many times. I must have seen it most every time it came there, because I was one of the chief men about the depot.

And yet this "chief man about the depot" says: "I cannot state what kind of brake that car had prior to about 1850. I have no recollection about what brake was on that particular car." And again, "I do not recollect distinctly what brakes were in use on the baggage, crate and passenger cars of the Camden & Amboy road prior to 1850."

It is needless to say a word about this. It proves nothing, except that a man might be the chief man about the Jersey City depot for many years, and might make the necessary slight repairs for the C. & A. cars, without knowing what kind of brakes those cars had on.

9. JAMES FERNALD, p. 429, conductor on the N. J. road from '37 to '63, says that the C. & A. cars, sent over that road prior to '49, had a single brake on each truck. But he says he does not know this from personal inspection, nor has he told us how he does know.

10. THOMAS O'MAHONY, p. 432, was another man in the Jersey City shop, from '46 to '61. *As far as he knows* the C. & A. cars, that came there between '46 and '49, had single brakes. He did not work on or look at the trucks, and can't say anything about what brakes they had on before '49. Is certain they would have adopted double brakes before '51, if the C. & A. cars had had them.

We will dispose of this argument of his hereafter.

11. A. C. CONDIT, p. 436, was on the N. J. road from 1841 to 1851. He is positive that there were single brakes on the Tyler car, and on the other C. & A. cars that came to Jersey City before 1851.

But it is difficult to believe him when he says that he inspected the brakes on the C. & A. cars—cars not belonging to his road—all through, often; twice a month, or oftener, all the time from '43 to '51.

He says too that he noticed the brakes very particularly *when they put on the double brake in* 1851, thus clearly implying that he had not noticed them particularly before. And why should he have noticed them before, unless he had heard that they were double? He had no motive for it.

12. E. T. MOORE, p. 443, was engineer on the N. J. road from 1846 to

1851; had C. & A. cars in his train every day. They had single brakes. Knew the Tyler car about three years, and saw it a great many times. *I know of my own knowledge that it had a single brake during those three years. It never had anything else on while I knew it.* I noticed the car particularly, as it was different from the other cars. I saw the brakes on the car quite often. While I was on the N. J. road from '46 to '51 there could not have been any double acting brakes on any of the C. & A. cars, that were in my trains, for any length of time, and I not have known it.

We ask particular attention to the above. This witness is as positive as a witness could be, and yet he afterwards took this all back. He says that no one was present on his former examination but *Sayles*, the complainant.

"I told him I knew the car, and had seen it frequently; in regard to the brake I told him I could not say whether it had a double acting brane or a single acting brake; it had a crank on the end. I told him I didn't know much about it; that I didn't think I would be of much use to him; that it might have had a double acting brake on, and it might not. I could not tell anything about it. I told him the first double acting brake I saw, to notice it, was on the New Jersey Central, in '52 or '53," p. 335. "Mr. Sayles asked me and I told him it might have had a double acting brake, and it might not; and I say so still. I had nothing to do with the cars. I would not swear what kind of a brake it had on." p. 336. The Cam. & Am. cars in my train might have had double brakes on; I would not have been likely to have known it. *I had nothing to do with the brakes. I did not at that time know the difference between a single acting and a double acting brake.*" p. 337.

If we could get at the truth, we should doubtless find it to be much the same with nearly all the appellee's witnesses. They knew that double brakes were introduced generally about 1851, and they are ready enough to believe that they could not have been in use before; and they swear accordingly, not from any positive knowledge, but partly from this impression, and partly because others have sworn to the same thing.

13. James McFarland, p. 469, is another characteristic witness. He is sufficiently positive that there were no double brakes on the C. & A. cars that came to Jersey City; but he had nothing whatever to do with those cars; he used to see them pass, and he used to examine them to see if they had any improvement. But there is no proof that he ever examined the Tyler car, or even that he ever saw it. And as the plaintiff never asked him a word about that car, it is fair to assume that he never did see it or had no recollection of it. If he did not remember that, his memory clearly is good for nothing.

14. Wm. Quigley, p. 477, is appellee's best witness. If he were uncontradicted by so many others his testimony would at once be received as true. But when we remember that there are at least twenty witnesses for appellant, every one of whom is at least as good as he, we are constrained to believe that his ardor has here carried him beyond the bounds of truth.

Quigley was only a boy in 1843. He was not at that time in the employ of the road, but was only hired now and then as an extra hand by the brakeman.

His mechanical ideas may have been great, as he says; and if there had been any reason for his examining the brakes on the Tyler car, his youth would be no great objection, but there was no such reason. He knew that the *Hodge* brake was generally introduced after 1851; he remembered that, of course, and he remembered too that this was the first time he ever heard of a double brake, and nothing would be more natural than for him to suppose that no such brake had been in use before. He doubtless *supposed* himself to be familiar with the brake on the Tyler car. But it is asking too much to ask us to believe that this boy kept up for so many years a careful inspection of brakes, that, so far as he knew, were precisely the same as all the other brakes on the road; or that he "recollected particularly about the brakes that were put on the Tyler car when it was rebuilt in 1843," or that he "distinctly recollected the brakes" from 1843 to 1851. We can understand how this might be where there was some marked improvement to fix attention and stimulate the memory, but not where the witness supposed there was no improvement.

Moreover, though *Quigley* swears he was brakeman, fireman or engineer on the C. & A. from 1843, the books show that he was not in their employ till 1847; pp. 358, 361, 363; and the truth is that previous to that time he was only employed by the men when they were sick or absent. pp. 560, 563.

15. R. VAN SYCKEL, p. 505, is quite positive that the Tyler car had single brakes from '43 to '46. But he was engineer and had nothing to do with the cars. And he says he thinks he never heard of a double brake while on the road, and that is why he is sure there was no such brake there. Cr. Ints. 22, 23.

16. J. COUNSELLOR, p, 516, is one of appellee's best witnesses, but his means of knowledge are not to be compared to those possessed by the witnesses for appellant. He was conductor not on the C. & A. but on the N. J. road. He says the Tyler car had single brakes, but does not say how he knew; does not say that he ever saw the brakes, or examined them, or operated them, or ever had the Tyler car in his train. To compare his evidence to that of men who made the brake, who put it on, who repaired it, who curiously examined it, to see how it worked, would be equally unjust and absurd.

17. I. W. VAN HOUTON, p. 525, was in the car shop of the N. J. road at Jersey City, and used to repair the Camden & Amboy cars that came there "to as small an extent as possible, with a view to safety in running." Does not remember ever seeing double brakes on any of those cars, and thinks he should if they had been running for any length of time, though it is possible they might have come there without his seeing them.

18. ISAAC NOSTRAND, p. 530, was baggage master on the C. & A. in '48, and conductor in '49. *Thinks* there were no double brakes on the Tyler car, but says I can only swear to my belief. I believe there was none. Never inspected the brakes, but formed his opinion only from working them. And he does not recollect that the Tyler car was re-built in 1849, but *thinks he would have known it if it had been.*

That is, he gives the same reason for believing that the Tyler car ~~would~~ not
could

have been re-built in 1849 that is given by most of his fellow witnesses for believing that it had no double brakes; and yet the Tyler car *was* re-built in that year, and no body denies it.

19. JOHN BRIGGS, JR., p. 533, was baggage master on the C. & A. in '49. They were then using all single brakes, I believe. If there had been any double brakes, I should have known it. Double brakes were put on about two years and a half after. He found it out by their stopping so much quicker. He never saw more than half their cars.

This evidence is of little weight. It does not appear that the witness ever saw the brakes, or ever operated them. He says himself he was not familiar with their construction. He says he knew of the Tyler car, but that is all he is asked to say about it.

20. CHARLES H. FRISBIE, p. 552, was fireman on the N. J. road between '46 and '49; used to see the Tyler car. I do not know of any brake on it except a single brake while I knew it. I *think* there could not have been any double brakes, on the C. & A. cars that ran into Jersey City, for any length of time, and I not know it. Was not then in the habit of noticing particularly any new improvements. Had nothing to do with the brakes.

21. PAT. H. FLANNEGAN, p. 556. This witness is one of the most positive of all produced by appellee. He was fireman on the N. J. road 3 years and 9 months; saw the Tyler car very often—frequently noticed the car, wheels, trucks and brakes; operated the brakes as often as twice a week; has looked under the car to see how the brakes were made. They were single brakes.

So far nothing could be more complete. But on cross examination he says: "*I mean by a single brake, a brake at each truck.* The brake wheel on the Tyler car had no ratchet. When I put the brake on I had to hold it with my hand, and when I let go of one end, it would let go what it held, until I could go to the other end. I am positive they were single brakes, because *I could screw up one end, and the other would be entirely at liberty.* I know it was at liberty for I tried it. I could not be at both ends of the car at once. When I would screw up one end, and run to the other, I would find it at liberty; there was no pawl and ratchet at either end of the car. The difference between a single brake and a double brake is, that one is a single brake, and the other is a double brake. *A single brake is on each end, or has a windlass on each end of the car;* double brakes are connected. I know there was no rods on the Tyler car to make connections. I could see it, passing by, that there were no rods. *I never thought of looking for any.*"

There are several points here to be noted. First. The witness thought the brake single because after screwing up one end, he found the other at liberty; whereas without a pawl and ratchet, this would be so with any brake. Second. He also concluded that the brake on the Tyler car was single, because there was a windlass at each end. What was the use of having two windlasses when you could apply all the brakes with one? was his reasoning. Third. He never thought of looking to see whether there were any connecting rods on the Tyler car.

All this was doubtless true of most of appellee's witnesses. They too reasoned in the same way. They too never thought of looking for the connecting rods. As we have said before, there was no reason why they should look unless they had first heard that the rods were there. Most of the appellee's testimony is easily explained in this way.

Finally, this witness swears that he did see some double brakes during the time he was on the N. J. road. They were on *a flat freight car*; that he cannot describe any double brake now in use; and does not know what brakes the Northwestern use on their cars; though then an engineer on that road.

22. **Benj. T. Seward**, p. 562, was fireman on the C. & A. in '43 and '44; then engineer till '50 or '51. Saw the Tyler car when rebuilt. Sometimes would see it every day; then not for a month or two. Could not say what brakes it had, but his opinion is they were single.

23. **J. Herbert**, p. 564, used to be brakeman on the C. & A. remembers Pres. Tyler going over the road; saw the car; it had a brake on each truck, and it took two men to brake both. He left the road about two years after.

But on cross examination he says first that he examined the brakes on the Tyler car at Bordentown the day it took the President over the road; because he had to see to the brakes when he was on the road; then that he was not on that train at all, and had nothing to do with the brakes, but was on another train. That when he came along he always cast his eye down on to the brakes and on the wheels too; whereas it was impossible to see the brakes in that way. He says that he has always had the brakes on the C. & A. and distinctly in his mind, so that he could have told at any time since what brakes were on the Tyler car; and that everything else connected with the car is just as fresh in his recollection. But on being asked to describe it, he contrives to be wrong every time. He thinks the seats were all alike—that it had *four* wheel trucks, and an *inside* privy—whereas the seats were *not* all alike—the trucks had *six* wheels, and the privy was *outside*.

The springs, which are also peculiar, he does not remember at all. And worse yet, he says there was then nothing new about the car, when everybody else says that it was just rebuilt, and was almost all new—a "silver palace car," but this witness did not seem to know that it had been rebuilt. And finally, he says, "I am near about sure that the car had a brake on each end. I am sure of that; I am sure;" thus showing that it was this fact which made him think it was not a double brake.

Nothing more can be needed to show the utter worthlessness of such testimony; but we may add that he had had a quarrel with Lockwood, and had been accused by him of theft.

24. **Geo. W. Teese**, p. 572 and 575, says he was engineer on the C. & A. about 5 or 6 years, and finally left in '51; that he knew of the Tyler car before he went on that road, and also after; that during the time he knew of her she had on the *Hodge* brake. Then that the first he knew of her having the *Hodge* brake was when he left the road in '51; before that she had a brake at each end operating on one truck; and so in '43. Being recalled he blows hot and cold, sometimes perfectly sure; "no mistake at all about it;" then he cannot "say exactly," and then "knows it, of course." But through it all he never says a word to show how he knew what kind of brakes were on the Tyler car.

No one on reading this whole testimony can help being struck with its thin and watery character as compared with appellant's. It is nearly all negative. It is what the witnesses did *not* see. The witnesses therefore may easily be mistaken. Or, as this court says in *Still v. Huidekoper*, 17 Wall. 394, "it is possible to forget a thing that did happen; it is not possible to remember what never existed." Out of all these witnesses only five or six say that they ever saw the brakes on the Tyler car, viz.: *Jeffries*, *Condit*, *Quigley*, *Flannegan*, and *Herbert*.

Hu[illegible] had the Tyler car in his train from '50 to '55, and he *thinks* in part of '49. He noticed it particularly *after it got double brakes*. And he says it had the *Hodge* brake on all that time; whereas the fact is, the *Hodge* was on only a short time, and was then superseded by the *Tanner*.

Counsellor does not say he ever saw the brake on the C. & A. cars; nor *Frisbie*, nor *Teese*.

O'Mahony says expressly that he never did, and can't say anything about it.

Nostrand can only answer to his belief, and he does not even remember that the Tyler car was rebuilt soon after he went on the road.

Morris and *Van Houten* and *Seward* say they can't tell of their own knowledge what brakes were on the Tyler car.

Ward has no recollection about it.

Reid recollects nothing about the car, except the seats.

Moore says he knows nothing.

Fernald and *Briggs* are asked by appellee if they recollect the Tyler car. They say they do, but there the matter is dropped.

George and *Silas Brown*, *Baker* and *McFarland*, are not even asked whether they remember such a car.

It is said, however, that if there had been a double brake on the Tyler car these witnesses must have heard of it. But this is by no means certain, still less that they would have remembered it. The Tyler car had 12 wheels, and this struck many of the witnesses as something very remarkable. But *Jeffries* did not remember this, nor *Herbert*. It had its saloon and privy on the outside, something still more peculiar; but *Herbert* had forgotten this also.

It was in every respect a remarkable car in 1848, when it took Pres. Tyler over the road, unlike any they had ever seen, a "silver palace car," fresh and new from the repair shop, but *Reid* can recollect absolutely nothing but the seats; while as for Herbert, though professing to remember everything, he in fact remembers nothing—not even that the car had just been rebuilt. And yet where one man would remember the brakes, twenty would remember these more showy features.

Again, if it be said that such an improvement could not fail to attract attention, we reply, first, that being used only on a few cars it would not be noticed; and second, that not one railroad man in ten can tell to day what kind of brakes is in use on his road.

I have had occasion during the last four years to talk with all sorts of railroad men, and to examine many as witnesses as to the various devices in use on their roads, and particularly as to the brakes; and have found hardly one who could tell me what they were then using, unless he had made examination for that express purpose, or had himself made the thing in question. A man may be a brakeman or conductor on the same car for years without being able to tell anything about the brakes; and it might almost be said that this was the rule rather than the exception.

The second set of witnesses for appellee consists of several of appellant's, who afterwards retracted. Great stress is laid on this, but we are not sure that our case is not helped by it quite as much as it is injured.

1. JOSEPH CAPNER, p. 571, is of little value either way. He had before testified that, when he went on the road in '47, there was a double brake on the Tyler car. He does not say now that there was not, but only that the *Hodge* brake was the first he saw, and he *thinks* that was in 1850, and that before this, the single brake was used on the C. & A. road. He says not a word to explain his former testimony, or how he came to change it.

2. H. H. DISBROW, p. 575, is of even less importance. The sum of both his depositions is simply this, that he has no recollection at all about the brakes.

3. R. C. WALCOTT, p. 588, is another of the same sort.

4. JAMES SEEDS, p. 602, had before testified quite positively that the Tyler car had a double brake in '44. He now says that he has thought the matter over, and thinks it was somewhere from '51 to '55 he first saw such a connected brake.

5. ASHER PANCOAST, p. 601, as we fully admit, was one of our best witnesses, and now turns against us. But we say confidently that his first story was the truth. It could not but be true. No man could ever have invented all those details. Afterwards he had a quarrel with the road, or was discharged, as *Lockwood* says, for drunkenness; and then falling into the hands of appellee, he was induced to change his testimony. We cannot positively say that he was bribed, that promises, more or less definite, were made to him by appellee, but we have

no doubt that such was the fact. And there is evidence enough in the case to warrant this assumption. Our own opinion is that, if all the promises of this sort made by appellee were to be righteously fulfilled, there would be little left of his decree. Though we admit that they were generally framed in such a way that it would be difficult to enforce them at law. It was not often that the appellee went so far as in the case of *Mrs. Nicholls*, where there was a plain promise to pay in case of success; saying nothing of the thousand dollar bond, which *Tanner* gave and *Sayles* assumed; but his approaches were usually much more guarded. Instead of a blunt promise he dealt rather in hints, plain enough to be understood, and yet vague enough to be denied.

This is what he said to *Lockwood:* "He said I must be mistaken, and he wanted to know *if he couldn't do something for me*, to say that I was mistaken as to date; he said if I could, that would leave a doubt as to the date of putting the brake on the car; he said it was worth hundreds of thousands of dollars to him, and he had a suit pending at Chicago for $40,000; and had it not been for the model called the John Tyler, Exhibit A, it would have been decided in his favor." p. 172.

Pancoast himself says that "*Sayles* has never promised me a cent, but I suppose every man has his price." p. 624.

Sayles told *Cudlipp* that "he had some $50,000 to spend in this case, and he was not going to be mean with it." "He said he understood I was the only man that could influence *Joseph F. Talson.*" "He wished me to see *Talson* in regard to this John Tyler car, and have a conversation with him; and see if I could not whet up my memory a little, and to ascertain what evidence there was against *Sayles* and his side of the question." p. 350.

"He represented the value of this patent right in the neighborhood of somewhere from one to three million dollars, as near as I can recollect, provided he gained the case that he had pending against railroad companies; he wished me to see *Talson*, and if I could influence him so far as to hold back what evidence he had collected for the railroad companies, and to go no further with his own evidence than to answer questions as they were put to him, that he would secure to me an income of ten per cent. of the whole income of said brake." "He afterwards agreed to go before any lawyer in New York, and secure me this ten per cent. income." Further, "when Sayles said he would agree to give me this ten per cent., which he thought would amount to the snug little sum of somewhere about $100,000, he said that I was at liberty to divide it with anyone, or do as I chose with it." p. 351.

He said to Talson, "Mr. Talson, I know you hold in your hand sufficient evidence to seriously injure my patent, or to kill it; but if you will not advance anything on this trial, and I win the suit, I will make you a very handsome present." p. 324.

Again, the contradictions in this second testimony of *Pancoast* show that he had now left the path of truth. Thus he first says that *Ryhow* told him there was a suit; that these parties had sued the Camden & Amboy Company, claiming $50 a car for every car it was used on, and then he began to count up how much it would come to—he said how much it would come to, but I don't recollect how much."

Being asked if *Ryhow* said anything about it being important for the Camden & Amboy Company to defeat the patent, he replies: "Yes, sir. *I don't recollect what he said.* I recollect he said it was a big thing for the company. p. 602.

Now in the first place it is impossible for *Ryhow* to have said anything about a suit, for there was no suit against the Camden & Amboy road, that road having been settled with years before, in 1855.

In the next place *Pancoast* says, when recalled, that *Ryhow* never said anything to him about it; and that he *Pancoast* said to *Lockwood*, "I don't see why the Company should take such interest in it. I understood *Mr. Van Rensselaer* had paid Sayles for his right." p. 625.

We insist then, that Pancoast's first story was the true one; that it has all the ear-marks of truth; that his second story has the marks of falsehood, and that in the charge of drunkenness against *Pancoast*, whether true or false, in his evident ill-will against the company, and in the wiles of appellee, we have furnished a sufficient explanation of his conduct. But he may not have been wholly dishonest. He talked with his old comrades and they changed his mind. These "old comrades" were in all probability, *Crim* and *Yundt*, who first deceived themselves and then deceived him, as we shall next show.

Crim and *Yundt*, as the court will recollect, were engineer and brakeman on the same train in 1845, in which *Pancoast* was a passenger, when the falling of one of its rods led them to examine into the construction of the brake. Being recalled by appellee *Crim* says he is not certain, but *thinks* he was mistaken not as to the time, but as to the character of the brake. After giving his first testimony, he says he "was in the Camden & Amboy yard, and thought he would just look at the cars, and see whether he was mistaken or no. He examined and found *the long rod running clear through the car—the brake* rod—and he came to the conclusion that *that rod* was not there, that is was not on at the time he was on the Camden & Amboy road." pp. 600, 601.

Now this, so far from weakening his former testimony, confirms it. The court will notice the reason he gives for thinking he must have been mistaken. He found on one of the cars in the Camden & Amboy yard a brake that had a long rod running clear through the car. There was no such rod on the brake that fell down in 1845, therefore he concluded that it could not have been the same brake. But a word will make this plain. The only brakes having this long rod running clear through the car are the *Stevens* and the *Hodge*. The *Tanner* has nothing of the sort. The witness happened to look at a car having the *Stevens* or *Hodge* brake; he knew that that was not the brake he saw in '45, and came at once to the conclusion that it could not therefore have been a double brake. His present testimony, therefore, only goes to show the correctness of his former statement, not to throw doubt upon it.

Yundt also examined the brakes and was deceived in the same way. And then they both deceived *Pancoast*, as above stated. Finally, however, *Yundt* seems to have found out his error; for having been recalled, not by appellant, but by appellee, he then says that the brake on the Tyler car in 1845 *was* a double acting brake. pp. 630, 631.

The appellee next attempts to rebut this evidence by showing that one or two of our witnesses had on previous occasions either said nothing about this use of a double brake on the Camden & Amboy road, or had expressly denied any knowledge of such use. The most important of these witnesses is *Lockwood;* and those called against him are *Moies*, *Hubbell*, *Waterman*, *Tanner* and *Sayles*.

Moies, p. 498, says that he went to Bordentown, he thinks, in 1851, to introduce the *Hodge* brake; that he spent nearly the whole day with the Superintendent of car repairs, explaining to him wherein the *Hodge* was superior to any other brake, and that he said if this was true, he would do all in his power to introduce it. They said nothing about their having used double brakes on their road. All they said was, they did not believe much in double brakes.

Tanner, p. 536, says he saw *Lockwood* in '51, and showed him the model he had made of his *Turner* brake, which was the same as the *Tanner*, as already explained; that he talked with him two or three hours, and he declined to put on the *Turner* brake at that time, because they had arranged to put on the *Hodge*, and that he said nothing about such a brake having been used on the C. & A. in 1843 and after.

Sayles, p. 454, says that he called on *Lockwood* in 1852, to introduce the *Tanner* brake; that he said *Tanner* had already shown him the model, but they had arranged to use the *Hodge;* that if he had seen the *Tanner* sooner, he thought he should have recommended that; and much more we cannot repeat. That he saw *Lockwood* again in 1853, and he said he had never heard of any other double brake till *Hodge* came there some two or three years before; that he was there again a number of times, and the C. & A. finally paid him for his brake $1,350; that nothing was ever said about their having used any double brake before, except the *Hodge*. And again, that he asked *Lockwood* in 1867 if he was not mistaken in regard to the time when the double brake was put on the Tyler car, and why they settled with him if they had used the *Tanner* brake since 1843; that *Lockwood* said it was a good while ago, and it was possible he might be mistaken as to the time: and that their folks would rather pay two or three hundred dollars than be bothered with a law suit.

Waterman, p. 465, says that in 1859 he saw *Lockwood*, and he said that they commenced with double brakes with the *Hodge;* that they afterwards applied the centre lever. "That was the distinct *impression* made upon me."

And finally, *Hubbell*, p. 543, says that he saw *Lockwood* in 1860, and he could not tell him when they first used double brakes; and the nearest information he could get from him was about 1851. "*Lockwood* did not talk much; he answered how the brake was constructed, but did not seem to know really much about it, particularly as to the time when first used, and I did not rely much upon him, but sought to get the information from *Mr. Dripps.* He never said anything about the use of a double brake on the C. & A. prior to 1848."

Now all this might be true, and still leave the testimony of appellant's other witnesses unaffected. But most of it is not true.

Waterman never saw *Lockwood* at all. This is proved not only by *Lockwood's* own denial, but by another witness, *N. F. Smith*, who remembers *Waterman's* visit, and all the circumstances, and swears positively that *Lockwood* was not in Bordentown at the time, and in consequence *Waterman* had to refer his matters to *Van Rensellaer.* p. 363.

The manner in which the plaintiff sought to dispose of this is so characteristic that we give it at length.

"Mr. Smith says, if I recollect right, that Mr. Waterman was there in the fall of the year, and that Mr. Lockwood was away. Now, if the court please, I don't know, and I don't care, whether Lockwood was there in the fall of that year, or the fall of any other year or not. The case was tried in *June*, 1859, as the clerk's minutes show, and Waterman testifies he was at Bordentown and saw Lockwood, and had this conversation shortly *before* that trial took place. Now, I submit to the court, of what materiality is it what Waterman did or who he talked to *in the fall of* 1859,—months after that case had been tried? That, I think, is enough to say about Mr *Smith's* attempt to deny *Waterman's* statement. It is of a piece with everything they have done in this case."

The unfairness of this is at once apparent when we learn that *Smith* states expressly that it was *just previous to this trial* that *Waterman* came to Bordentown to see *Lockwood;* that he went to *Smith's* brother to get him to go *as witness in that trial*, and *Lockwood* being away, permission had to be obtained from *Van Rensellaer.* The time is thus fixed beyond dispute, and the mere fact that *Smith* thought it was in the fall, so much dwelt on by plaintiff, becomes of no importance. Moreover, *Waterman himself, the very witness the plaintiff is here trying to sustain, made precisely the same mistake.* He says, "I think it was sometime in *the latter part of* 1859, a short time previous to the trial at Canandaigua." p. 465.

Lockwood swears that "Waterman never called on me to my knowledge; but I understood a man did call to see me, and I was not in Bordentown; but when I returned, either from Tarrytown or Newburgh, I can't say which, my foreman, Mr. Smith, informed me that there had been a person there to see me in reference to car brakes; my not being present, Smith saw Mr. Van Rensellaer, and he gave his consent for Smith to go to Canandaigua, as a witness on a trial in reference to brakes." p. 380.

Tanner and *Sayles* are both interested parties, *Sayles* especially, who has testified in this case over and over again, and who has been contradicted every time. *Lockwood* flatly contradicts them both, and his unsupported word is in this instance better than both of theirs.

The statement made by *Hubbell* is wholly inconsistent with those of his fellow witnesses. *Moies* had had a long talk with *Lockwood* about the *Hodge* brake in 1851; *Tanner* another in 1851, when the brake was introduced. *Sayles* called on him in 1852, again in 1853 a number of times; then in 1854, and once more in 1855. Yet when *Hubbell* saw him in 1860, "he did not seem to know really much about the brake." p. 547.

Finally, this is "that most unsafe of all testimony, conversations and confessions—remembered or imagined—partly stated or wholly misrepresented." *Badger v. Badger*, 2 Wall. 93. It is evidence largely of interested witnesses—for if we throw out *Sayles* and *Tanner*, the others amount to little—of conversations that occurred ten to fifteen years before.

It may be said, however, that if the *Tanner* brake had been in use on the C. & A. road since 1843, *Lockwood* would have been sure to say so, and these witnesses to remember it. But that depends on the object these witnesses had in view. If *Moies* saw *Lockwood* at all, he went there simply as agent of *Hodge*, to introduce the *Hodge* brake. He was already familiar with the *Tanner* brake, though not by that name, and was firmly convinced of its great inferiority to the *Hodge*. It was to him therefore a matter of little moment whether the *Tanner* brake had been used on the C. & A. road in 1843 or not. There was no reason for *Lockwood's* telling him, and no reason why he should remember it if told.

The same is true of *Waterman*. All he wanted was to defeat the *Hodge* patent, or to show that it was no better than the *Tanner*, which he already knew was prior to it. It could not have aided him in the least as to either of these matters to know that the *Tanner* brake had been used on the C. & A. as early as 1843.

Hubbell, we admit, ought to have found out about this use, but it is not at all incredible that he should not. It is much easier to account for his failure than it is to explain how the twenty-five or thirty witnesses for appellant could be mistaken. As we have already said, there is something a little singular about this interview between *Hubbell* and *Lockwood*. To read *Hubbell's* statement, it would seem that *Lockwood* had very little knowledge of brakes of any kind. But this is out of the question. The only conclusion we can come to is that *Lockwood* did not happen at the time to be in a communicative mood, or his mind may have been occupied with other matters. It is not true that railroad men, any more than lawyers, are always ready to tell all they know to every stranger that seeks to interview them.

But again it may be urged in this connection that the Cam. & Am. would never have paid for the *Tanner* if it had been on that road since 1848. We do not know how this will strike the court, but no one who has ever had a share in the management of a railroad would give it a thought. Those unfortunates have been too long used to paying for patents that they fully believe to be invalid, to regard such an act as any admission to the contrary. Their experience has been too much like that detailed by *Dripps*, where the Cam. & Am. road spent thousands of dollars in the *successful* defense of a patent suit they could doubtless have settled for as many hundreds. p. 369.

So *Van Rensellaer* says that the President of the C. & A. settled for the *Hodge*, not acknowledging its validity, but to avoid litigation, *and that Lockwood objected to paying for this Tanner brake on the ground that it was already in use on their road.* p. 273. The court will remember that the date of the invention of a patent is almost always an unknown quantity; that the life and memory of witnesses are uncertain, and that the officers of a road who settle for a patent are not often the ones who have any personal knowledge of its prior use.

The remaining evidence for appellee on this point is of the strangest sort, and such as could never have been so much as thought of, except in a patent suit, where all the known rules of evidence are so constantly held for naught. This is the evidence of *Gifford*, *Grosvenor*, *Hubbell*, *Keller* and *North*, the attorneys engaged in the suits of *Tanner* against the Erie and Hudson R. roads, as to what was done in those suits to defeat the patent. It was chiefly hearsay, and except so far as it concerned the witnesses in the present case, *res inter alios acta*, and should never have been admitted into the suit, or only for the purpose of an injunction. But these witnesses have not only been allowed to tell what they did themselves, but everything that was told them by others. And to cap the climax, some of the defendant's lawyers in those suits, *who are now retained by the patentees*, are here asked to give their *opinions* as to our several defences, and it never seems to have occurred to any one that this evidence was not competent. But even admitting it to be competent, it is still of little weight. These parties failed to hit upon this Camden & Amboy brake, but what then? They profess to have been very zealous to defeat these suits, and perhaps they were. But both those suits were settled for small amounts, a thousand or two of dollars in each case; though if the amount had been a hundred times as great, the result might well have been the same. The court is familiar with the Hyatt patent for sidewalk lights, now so common in all our streets. That patent was granted in 1845; it was sustained by the courts; it was twice extended, in spite of vigorous opposition; it was a very valuable patent, having yielded at least a million dollars and probably twice that amount to its owners. In 1872, or 27 years after its issue, one of the defendants in a suit brought upon it went to London to see if he could not find a defense, though he knew that the same ground had been gone over before. He returned in about six weeks, bringing with him a large printed volume, well known

$1000. in one case
and $75 in the
other. p 496; 695.

in this country, containing some 25 descriptions of the device accompanied with drawings. He brought also a light which had been worn as thin almost as a knife by the millions of feet that had walked over it in London streets. He brought a trade circular containing page after page of descriptions and drawings, and a frontispiece showing the maker's shop on a corner in London with the lights in the sidewalk and leaning up against the front of the building. There must have been at least a hundred thousand people in London who had seen these lights a thousand times; the thing was far more notorious than this Camden & Amboy brake, parties had been to London expressly to hunt for it, and had come away without finding it.

Finally, the court below says "There is one fact established, which unexplained, seems to be conclusive on this part of the case. The counsel for the defense do not controvert the value or utility of the *Tanner* brake. Now if there was such a brake in substance or effect on the car referred to, then it was not attached to the other cars of the C. & A. road, because the proof appears ample that some years after 1843 the cars were run generally with the single brake alone, and if it were true that a double acting brake included in the model of the Tyler car, existed in 1843, it is scarcely possible to doubt that it would have gone into general use at once on the road." p. 67.

This argument, on which the court so largely relied, is plausible but wholly unsound. In the first place, as this court has said, "There is no force in the argument drawn from the wisdom that comes after the event." It is not safe to judge 1843 by 1875. Because the utility of double brakes is now generally proved and acknowledged, we have no right to assume that the same was true thirty years ago.

"Being schooled as we are now to the use of the double brake we would not consider it safe to depend on the brakeman running through the car, first applying the brake on one end, and then on the other; but we did consider it so, 18 or 20 years ago; that was the custom." Dep. of S. J. Hayes, p. 961.

But second, it is a still greater mistake to suppose that new improvements are so readily adopted as the above argument assumes. On the contrary it is oftener the work of years. The two greatest improvements ever made in railroading are the Miller platform and the Westinghouse brake. Yet it took years to introduce them even on the leading roads, and many are without them still. And twenty years after the double brake was known, many roads continued to use the single brake alone. Finally the very thing the court below thought so incredible is proved by the plaintiff in this case to have happened on two other roads. Batchelder, one of these pretended inventors, swears that he applied the *Tanner* brake on a car on the Fitchburg road in 1847, and that it worked to his entire satisfaction, p. 93. If the court below is correct, then this brake ought "at once to have gone into general use on that road." But the fact is that the Fitchburg road continued to use the single brake on all its other cars till 1851, when they adopted not the *Tanner*, but the *Hodge*, precisely as happened on the Camden & Amboy. In 1848 Batchelder swears that he applied it in like manner on the Boston & Lowell road, but there too they went on using the single brake till 1851, when they adopted the *Hodge*.

So too on the New Jersey road *Brown* says they put on the first double brake in 1851, but it was not till 1856 or '7 that they gave up the single brake. p. 868.

The fact is it takes long to satisfy the various officers of a railroad of the necessity of a change. For this there are many reasons. A thousand different so-called improvements are all the time being urged upon them. Some of these work well for months or years, and then develop defects before unseen. Or they work well, but are supplanted by something better. Or the officers, who alone have the power to make the change, are not aware of its necessity. The Master Mechanic must see the Superintendent, the Superintendent the President, and the President the Directors. It is often only after years of such consultations that the change finally comes. Nowhere in short is Paul's advice better heeded, to "prove all things, hold fast that which is good."

In conclusion we must say that it seems to us, this defense is fully made out. The evidence on the other side is all capable of full explanation. But there is no possible explanation of appellant's testimony, except on the theory of its truth. If the court will look again at the evidence of *Coulter*, *B. L. Walcott*, *J. C. Hillman*, *Chas. Cox*, we might add a dozen more, we think they will agree with us that if such a matter ever can be proved, we have proved it in this case.

III.

THE INFRINGEMENT.

There are three kinds of double brakes now and for the last 25 years in use, the *Tanner*, the *Stevens* and the *Hodge*. The *Tanner* is little used, most of the roads having preferred the *Stevens* or the *Hodge*. It is claimed, however, by the plaintiff that both of these are infringements of the *Tanner*, but this we wholly deny. The brake used by defendants is the *Stevens*, and that is the only one now before the court. We will first state what we believe to be the law, and then apply that law to the facts. We admit,

First. That two things may *look* very unlike, and yet be the same.

Second. That mere formal changes, changes that do not go to the substance of the invention, are not enough to avoid infringement.

Third. That to use the *principle of an invention* is an infringement, no matter what *formal* changes may be made.

Fourth. That no one has a right to use the patented device, no matter what improvements of his own he may add to it.

But on the other hand we say,

First. That the *principle* of a machine or a combination is not an *abstract idea*, but only that idea when embodied in a visible shape.

Second. If there can be no patent for an abstract idea, of course there can be none for a result. And if none for a result, then none for *all ways* of producing that result. Anyone has a right to produce the same result, provided he employs different means. It is the *specific means* employed, or their equivalent, that is patented; and unless we use those means there is no infringement.

"The word '*principle*' is used by elementary writers, and sometimes by courts, with such a want of precision as to mislead. It is admitted that a principle is not patentable." *LeRoy v. Tatham*, 14 How. 174.

"The end to be accomplished is not the subject of a patent. The invention consists in the new and useful means of obtaining it." *Carver v. Hyde*, 16 Pet. 519.

"The patent embraces nothing more than the improvement described and claimed as new; and any one who afterwards discovers a method of accomplishing the same object, substantially and essentially differing from the one described, has the right to use it." * * "The patent confers the exclusive right to use the means he specifies to produce the result or effect he describes, and nothing more." * * "And any one may lawfully accomplish the same end without infringing, if he uses means substantially different." *O'Reilly v. Morse*, 15 How. 119.

"The patentee is protected against any other device which involves substantially the same principle. But if another produces the same result by means different in principle and application, it is no infringement; for it would be absurd to say that a patent covers all possible ways of producing the same result." *Lee v. Blandy*, 2 Fish. 95.

"There cannot be a patent for a principle; nor for the application of a principle; nor for an effect. Two persons may use the same principle, and produce the same effect by different means, without interference or infringement, and each be entitled to a patent for his own invention." Bain v. Morse, Law's Dig. 259.

"We find here no authority to grant a patent for a "principle," or a "mode of operation," or an idea, or any other abstraction. A machine is a concrete thing, consisting of parts, or of certain devices and combination of devices. The principle of a machine is correctly defined to be its mode of operation, or that peculiar combination of devices which distinguish it from other machines. A machine is not a principle, or an idea. The use of ill defined abstract phraseology is the frequent source of error." *Burr v. Duryee*, 1 Wall. 570—578.

See also *Case v. Brown*, 2 Fish. 273, 2 Wall. 327; *Stone v. Sprague*, 1 Story, 270; 2 Robb. 10; *Singer v. Walmsley*, 1 Fish. 563-9; *Amer. Pin Co. v. Oakville Co.*, 3 Blatch. 192; *Werner v. King*, Off. Gaz. 13, 178.

Third. There can be no infringement of a combination unless all the parts are used, or their equivalent. *Prouty v. Ruggles*, 16 Pet. 341; *Brooks v. Fiske*, 15 How. 219; *Vance v. Campbell*, 1 Black, 429; *Eames v. Godfrey*, 1 Wall. 80; *Rich v. Close*, 4 Fish. 283; *Case v. Brown*, 2 Ib. 274.

"The defendants do not infringe, for the combination which they use is not Shaw's combination. It discards one of Shaw's elements, as he has described them, and includes a device not found in Shaw's combination, which performs, in the defendants' machine, a function not performed by any device in Shaw's." *Knox v. Martha*, 5 Fish. 181.

Fourth. And even though all the parts are used, yet if they are *arranged and combined* in a substantially different way, there is no infringement.

"The use of any two of these parts only, or of two combined with a third, which is substantially different in form, or *in the manner of its arrangement and connection with the others*, is therefore not the thing patented." *Prouty v. Ruggles*, 16 Pet. 341.

"If either the devices or *the mode of applying them* in any other machine, is substantially different from the plaintiffs, it is not the same." *Eames v. Cook*, 2 Fish. 148; *Carver v. Hyde*, 16 Pet. 513; *Singer v. Walsmley*, 1 Fish. 578, 582; *Case v. Brown*, 2 Ib. 274; *Stimpson v. The Railroad*, 10 How. 345; *Eames v. Godfrey*, 1 Wall. 80; *Seymour v. Osborn*, 11 Wall. 555.

Fifth. There can be no infringement unless the two machines employ the same means—operating in the same way—and producing the same result. All of these things must be proven to make out that substantial identity that constitutes infringement. *Cahoon v. Ring*, 1 Fish. 419; *Foss v. Herbert*, 2 Ib. 85; *Eames v.* Cook, Ib. 148–151; *Cox v. Griggs*, Ib. 178: *Westlake v. Carter*, 6 Ib. 525, 6, and *Burr v. Duryee*, 1 Wall. 572, 3, are all very clear on this point. See also, *Smith v. Downing*, 1 Fish. 83; *Many v. Sizer*, Ib. 24; 40–43; *Page v. Ferry*, Ib. 314; *Morris v. Barrett*, Ib. 464; *Blanchard v. Putnam*, 3 Ib. 196; *Conover v. Roach*, 4 Ib. 26; *Conover v. Rapp*, Ib. 62; *Carter v. Baker*, Ib. 408; *Merriam v. Drake*, 5 Ib. 263.

Sixth. The result here spoken of is not the same *general* result, but the *specific* result.

"It is true that the general object of the two is the same, and so it is with all rival inventions. But this of course does not necessarily make all new inventions or patents for like objects an encroachment on all previous ones. Such a doctrine would discourage progress rather than encourage useful arts, as the constitution wishes to be done by granting patents. It would, after one invention as to the same subject, principle, or art, halt and bar all further advances on the same subject." *Smith v. Downing*, 1 Fish. 84.

"By an abuse of this doctrine of equivalents, experts may demonstrate every machine which effects a certain purpose to be the same with every other that effects the same purpose." *Sickles v. Gloucester Man. Co.*, 1 Fish. 284.

Seventh. There is no infringement if the difference, whether in the means employed—or in the mode of operation—or in the result, *involves invention*; unless the difference consists solely in some *addition* to the plaintiff's machine; retaining all that was his, and adding something more. *Pitts v. Wemple*, 2 Fish. 19; *Foss v. Herbert*, Ib. 36; *Case v. Brown*, Ib. 272, 5; *Rich v. Lippincott*, Ib. 5; *Carter v Baker*, 4 Ib. 407, 416; *McCormick v. Seymour*, 2 Blatch. 245; *Blanchard v. Beers*, Ib. 420.

" Such an alteration is not a mere formal alteration, *as the difference between the two improvements is such that the new combination would be the proper subject of a patent*, and consequently would avoid the charge of infringement in a case like the one supposed by the court." *Gould v. Rees*, 15 Wall. 193.

Eighth. There is an important distinction here between *addition* and *substitution.* If I add something to the plaintiff's invention, I infringe, even though my addition be also patentable. But if I leave out a part of his combination, and substitute something of my own, constituting a patentable improvement, there is no infringement.

" If an improvement can be made by one skilled in the art without invention, then the one is substantially the same as the other. " But if he is obliged to go to invention, then he has a right to the benefits of whatever he thus invents; and if his invention is a *substitution* for the original invention, then it is not substantially the same, and he does not use it. But if he merely invents something to be *added* to it, then he cannot take the original invention, because he has made something distinct to add to it, as a new improvement." *Johnson v. Root*, 1 Fish. 364, "Adding and improving as much as they may, if defendants have taken plaintiff's combination they are liable for the use of that. It is true there may be a distinction of another kind; if a defendant does not *add*, but *makes a change*—improves one part of the machinery used—he may do that, and not be liable in the common acceptation of the term; and it might not be considered as a separate and additional improvement, but a change which is made by itself." *Colt. v. Mass. Arms Co.*, 1 Fish. 125. See also *Pitts v. Wemple*, 2 Fish. 18, 19, just cited; *Eames v. Godfrey*, 1 Wall. 80; *Gould v. Rees*, 15 Wall, 194, and *Richardson v. Noyes*, Off. Gaz. 10, 508; *Potter v. Holland*, 1 Fish. 390–2, where this point is very fully presented.

Ninth. This furnishes us with the safest and most exact definition of an *equivalent.* It is what can be substituted without invention, by the ordinary skill of mechanics.

Tenth. It is not enough for the plaintiff to show that the thing substituted is an equivalent; *he must also show that it was well known at the date of the patent as a proper substitute for the one omitted. Roberts v. Harnden*, 2 Cliff. 504; *Gould v. Rees*, 15 Wall. 194, and cases there cited; *Gill v. Wells*, 22 Wall. 28, 32. *Tafts v. Boston Mach. Co.*, Off. Gaz. 8, 240. *Union Sugar Ref. Co. v. Matthiessen*, 2 Fish. 629; *Fuller v. Yentzer*, 4 Otto. 297. And the same has long been the rule in England.

Eleventh. Increased utility is evidence tending to show that there is no infringement. *Many v. Sizer*, 1 Fish. 24; 40, 41; *Johnson v. Root*, Ib. 362; *Eames v. Cook*, 2 Ib. 149; *Woodman v. Stimpson*, 3 Ib. 98. *Mitchell v. Tilghman*, 19 Wall. 418.

The whole law on this question may be summed up as follows: There can be no infringement of the plaintiff's combination, unless we use all its parts, or their equivalents. And the parts used by us are not equivalents unless well known as proper substitutes at the date of his patent. Nor unless they are combined in the same way—and operate in the same way—and produce the same specific results. Nor unless they could have been substituted by the ordinary skill of mechanics, without invention.

Now there is not one of the above rules but what is settled beyond question. And there is not one of them but what must be disregarded in order to find infringement in this case.

Thus defendant's combination is different—its parts are different—their arrangement, connection and results are all different; and finally all these differences are beyond question substantial and material; they constitute a patentable invention—that invention has been patented, and the patent has been sustained by this court—we have a license under it, and it is by virtue of that license we have used the *Stevens* brake. If we have used anything that legally belongs to the plaintiff we are willing to pay him for it; but we deny that we have done this—we insist that we are here acting under an independant invention, and we claim its protection, as the courts have said we may do. *Westlake v. Carter*, 6 Fish. 526; *Corning v. Burden*, 15 How. 271; *American Pin Co. v. Oakville Co.* 3 Blatch. 192.

And finally the burden of proof is here upon the plaintiff, and every doubt is to be resolved in favor of defendent. *Many v. Sizer*, 1 Fish. 22; *Brooks v. Jenkins*, 3 McLean, 432; *Washburn v. Gould*, 3 Story, 142; *Cahoon v. Ring*, 1 Fish. 403.

We come now to compare the two machines. In Batchelder and Thompson's original petition, specification, and oath the invention is said to be "an improvement upon the car brake now in general use;" in the new specification, "a new and useful *mode of operating* the brakes of railway cars;" and in the patent, "a new and useful improvement in railroad car brakes." The specification, after describing the invention, and disclaiming the mode of applying all the brakes at once, as patented by Griggs in 1839, concludes as follows:

"BUT WHAT IS CLAIMED BY US IS TO SO COMBINE THE BRAKES OF THE TWO TRUCKS WITH THE OPERATIVE WINDLASSES OR THEIR EQUIVALENTS, AT BOTH ENDS OF THE CAR, BY MEANS OF THE VIBRATING LEVER A′, OR ITS EQUIVALENT, OR MECHANISM ESSENTIALLY AS SPECIFIED, AS TO ENABLE THE BRAKEMEN BY OPERATING EITHER OF THE WINDLASSES, TO SIMULTANEOUSLY APPLY THE BRAKES OF BOTH TRUCKS, OR BRING OR FORCE THEM AGAINST THEIR RESPECTIVE WHEELS, AND WHETHER HE BE AT THE FORWARD OR REAR END OF THE CAR."

Or more briefly, "COMBINING THE TWO SETS OF BRAKES AND WINDLASSES, BY MEANS OF THE VIBRATING LEVER A′, OR ITS EQUIVALENT, SO AS TO APPLY ALL THE BRAKES AT ONCE FROM EITHER END."

Now whatever else the inventors *might* have claimed, what they have claimed is certainly clear. This is not a claim for a double brake generally; that is, for any and all kinds of double brakes; as seems to have been supposed by the court below; nor is it, as insisted by the plaintiff, a claim for any and all modes of combining the brakes by means of an "*intermediate lever connection*"; but it is simply a claim for combining them by means of the *vibrating lever A′, or its equivalent.*" This lever, as their own expert declares, is the "*controlling element.*"

Whether they invented anything more than this, or whether they might have had a broader claim, is not necessary to inquire. All that the public are required to do is to take the claim as they find it. And any one reading this claim would have a right to conclude that all the inventors meant to claim was the means specified; viz., *the vibrating lever A′, or its equivalent*, and that every other mode he was at entire liberty to use. As this court has said in a recent case, *Keystone Bridge Company v. Phœnix Iron Company*, "When a claim is so explicit, the court cannot alter or enlarge it. * * When the terms of a claim are clear and distinct (as they always should be) the patentee is always bound by it. He can claim nothing beyond it." And so in *Merrill v. Yeomans*, 4 Otto 573.

With such a precise and definite claim, then, we think there should have been no difficulty in settling this question. The single point was this, Did defendants use the vibrating lever A′ or its equivalent? But our misfortune is that the learned judge who heard the case below seems at times to have entirely lost sight of this. True he refers to the claim in one part of his opinion, but he nowhere undertakes to point out this equivalent. And in another part of the case he evidently goes on a very different theory. Thus in his second interlocutory decree he says "that the thing patented and covered in and by the said letters patent is the combination of all the brakes of a car with the windlasses, so that the brakeman, by operating either of these windlasses, can apply simultaneously all the brakes. p. 34—35.

And in his second opinion, "According to the view which the court takes of the evidence, Bachelder & Thompson first successfully combined the two systems of brakes with each other and with the windlasses, so that all the brakes could be applied at either end of the car. *This was their invention, secured by letters patent to Tanner.*" p. 69.

We respectfully submit that this is not a correct view of the law. Whether they were first in the field or not, the inventors never could have had a claim for "combining the two sets of brakes with each other and the windlasses, so as to apply all the brakes at either end of the car." The most they could have claimed in any event was their specific devices or their equivalents. Subsequent inventors like Stevens would still have an undoubted right to do the same thing, provided they did it in a substantially different way, or by substantially different means. But much more is this the case when, as we have just seen, the inventors, confine themselves by the very words of their claim to "the vibrating lever A′ or its equivalent."

The rest of the opinion of the learned judge is what would be expected from such a construction of the claim. He gives us no analysis of either patent, nor does he anywhere inform us in what the infringement consists. We are simply told, in one place, that *Stevens* has taken the *inventive principle* of the *Tanner* combination, and evolved something different and better by additional devices; in another, that the only question is whether the Stevens brake *embodies the Tanner invention.*

We cannot protest too strongly against this mode of dealing with a great and important question. It strikes us as at once unsafe, unjust and unsatisfactory. It is very easy to say that one machine "*embodies the invention of another,*" or "*contains the inventive principle of another,*" much easier than it is to analyze the two machines, and point out those parts in the one which answer to those in the other. But this very ease is what makes it so unsafe. If the learned judge had gone on to point out in the Stevens an equivalent of the Tanner centre lever, his well known learning and experience would, we believe, have brought him to a very different conclusion.

The view taken by the court below is still farther obscured by what is said in other parts of the opinion. Thus we are first told that the case is to be decided according to the rule in *McCormick v. Talcott*, 20 How. 402. But the rule there laid down is, that "the inventor of the first improvement cannot invoke the doctrine of equivalents to suppress all other improvements which are not mere colorable invasions of the first." According to this view, therefore, the Stevens is "*a mere colorable invasion*" of the Tanner, a proposition we cannot believe the court meant to assert, and which we cannot be seriously called to refute.

A little further on we are referred to *Seymour v. Osborne*, as ruling that "inventors of a combination are as much entitled to suppress every other combination of the same ingredients to produce the same result not substantially different from what they have invented and patented, as any other class of inventors; and they have a right to invoke the doctrine of equivalents to that extent to sustain their invention."

But the rule in *Seymour v. Osborne* further is that "the inventor of a combination cannot treat anyone as an infringer whose machine does not contain all the material ingredients of the prior combination, as in that state of the case the subsequent invention is regarded as substantially different from the former one, unless the latter machine employs as a substitute for the ingredient left out to perform the same function, *some other ingredient which was well known as a proper substitute for the same when the former invention was patented.*" And that inventors of a combination have, as well as other inventors, "*the right to suppress every colorable invasion.*" p. 556.

From this it would seem that the court either mistook the rule in *Seymour v. Osborne* or else meant to decide that the Stevens combination had all the ingredients of the Tanner, or well known substitutes; a proposition impossible to be maintained, as we shall presently show.

We come next to the argument of the patentees. They admit in the outset that they are not entitled to claim *all modes* of combining the two sets of brakes. They are well aware that neither the law nor the claim would allow them to go to that extent; they have been compelled therefore to seek out some narrower construction, which, while seemingly more in accordance with the law, should yet be broad enough to embrace the Stevens brake.

The construction they finally settled upon was this: that the patent "COVERED ANY MECHANISM WHICH CONNECTS THE BRAKES OF THE TWO TRUCKS WITH THE WINDLASSES, SO AS TO PRODUCE THE RESULT STATED, BY MEANS OF A CONNECTION—BY WHATEVER ARRANGEMENT OF LEVERS—LOCATED INTERMEDIATELY BETWEEN THE BRAKE SYSTEM AND THE WINDLASSES SUBSTANTIALLY IN THE MANNER SET FORTH."

That is, to state it more briefly, they now claim "ANY INTERMEDIATE LEVER CONNECTION SUBSTANTIALLY AS SET FORTH."

Now we submit that this mode of stating their claim does not help the matter at all, except so far as it tends to mislead. It is a mere form of words which, whether intended to have that effect or not, simply obscures what before was perfectly plain. For it is clear that the patentees have no more right to claim *all modes* of combining the brakes by means of an "*intermediate lever connection*" than they have to claim *all modes* generally. Inserting these words, therefore, in place of those found in the claim, viz., "*by means of the vibrating lever A′, or its equivalent*," strikes us as nothing more or less than an evasion. It certainly implies, even if it does not directly assert, that *any* intermediate lever connection is an infringement. If that is not its meaning, why make any change in the claim?

It is no answer to this to say that they claim this intermediate lever connection only substantially as described. For if that is what this new claim means it means nothing. If we use the device substantially as described we infringe, and there is an end of it; there is no need of saying anything about an "intermediate lever connection." If we do not use substantially the same device, we do not infringe, whether we use an "intermediate lever connection," or any other. Admitting, however, the right of the patentee thus to construe the claim it only makes our case the stronger; for it is very certain that whatever else we use, we do not use any "intermediate lever connection" whatever to combine the two sets of brakes. The patentees indeed assert the contrary, as their own construction of the patent of course drove them to do, but when the court comes to see the position they have here to assume, its entire absurdity will we think become apparent at once.

Cooper, their sole expert on this part of the case, at first says that he is "clearly of opinion that the *Stevens* patent *embodies the invention* claimed in the *Tanner;* all the brakes in the *Stevens* are applied by operating either windlass as in the *Tanner*, the center lever is dispensed with, for the reason that the power is applied directly to the brake levers, and by them is transmitted to the other truck; the brakes of the two trucks are connected by means of rods in such a manner that all that is performed by the *Tanner* is also accomplished by the *Stevens;* the difference is one of form and not of essence up to the point when the *Tanner* invention ceases, and the *Stevens* begins." p. 106.

But he is very careful not to tell us where that point may be found; if he had, we should have seen at once that it was an abstraction merely, an imaginary point incapable of any local habitation, and becoming a vanishing point the moment we try to seize it. So he tells us that the Stevens brake "*embodies* the Tanner invention," that most vague, plausible and convenient formula when one wishes to prove one thing to be an infringement of another, and does not know exactly how to do it. Being asked, however, on cross examination, to state his reasons, he at last comes out with this truly astounding statement, astounding even for an expert, that *the equivalent of the Tanner centre lever is to be found in the Stevens in one of the brake levers!*

Whatever may be thought of this ingenious theory, it has at least this merit, that it reduces the question of infringement to the briefest compass, and presents it in the most definite, tangible shape. What we had most to fear, in fact, the only thing we had to fear was that the matter might be left in the same vague, shadowy condition in which it was left by *Cooper* on his direct examination, and in which, as we have just seen, it was left by the court. The question now is simply this, Is the equivalent of the Tanner centre lever to be found in any one of the Stevens brake levers? We say as to this that it is not an equivalent; for it is combined and arranged in an entirely different way—it operates in an entirely different way—it was intended to produce and does produce entirely different results—it could not have been made without invention—it has never been pretended that it was a substitute well known at the date of the plaintiff's patent—in short it would be hard to find two things more totally unlike.

If we look now at the Tanner brake we shall find its parts combined as follows. The power is first communicated from the windlass by means of its rod and chain to one end of the centre lever A'. There the power is divided, part being sent back to the brake lever in the nearest truck, and the rest sent forward to the brake lever in the farther truck. There are thus five elements which serve to combine the windlasses with each other and the two sets of brakes; viz: the two rods running from the windlasses to the centre lever—the centre lever itself—and the two rods running from it to the brake levers. The centre lever is here, as said by Cooper, the "*controlling element.*" p. 116.

This centre lever is not a brake lever; it is not even a part of the brake mechanism proper; but a separate and distinct device, added to the brake mechanism for the sole purpose of receiving, transmitting and increasing the power. Or, as described and claimed in the patent, it is the means employed to connect the two sets of brakes. Or, to adopt the language of the patentees in their construction of the claim, it is the "intermediate lever connection." In whatever way we look at it, it is *an extra device outside of the brake levers.*

In the Stevens, on the contrary, the levers are all brake levers, and nothing but brake levers. They are all just alike. There are two in each truck, instead of one as in the old single brake and the Tanner; but this new lever is still as much a brake lever as the old one. It is not in any sense a centre lever. It is to that extent; they have been compelled therefore to seek out some narrower construction, which, while seemingly more in accordance with the law, should yet be broad enough to embrace the Stevens brake.

The construction they finally settled upon was this: that the patent "COVERED ANY MECHANISM WHICH CONNECTS THE BRAKES OF THE TWO TRUCKS WITH THE WINDLASSES, SO AS TO PRODUCE THE RESULT STATED, BY MEANS OF A CONNECTION—BY WHATEVER ARRANGEMENT OF LEVERS—LOCATED INTERMEDIATELY BETWEEN THE BRAKE SYSTEM AND THE WINDLASSES SUBSTANTIALLY IN THE MANNER SET FORTH."

That is, to state it more briefly, they now claim "ANY INTERMEDIATE LEVER CONNECTION SUBSTANTIALLY AS SET FORTH."

Now we submit that this mode of stating their claim does not help the matter at all, except so far as it tends to mislead. It is a mere form of words which, whether intended to have that effect or not, simply obscures what before was perfectly plain. For it is clear that the patentees have no more right to claim *all modes* of combining the brakes by means of an "*intermediate lever connection*" than they have to claim *all modes* generally. Inserting these words, therefore, in place of those found in the claim, viz., "*by means of the vibrating lever A′, or its equivalent*," strikes us as nothing more or less than an evasion. It certainly implies, even if it does not directly assert, that *any* intermediate lever connection is an infringement. If that is not its meaning, why make any change in the claim?

It is no answer to this to say that they claim this intermediate lever connection only substantially as described. For if that is what this new claim means it means nothing. If we use the device substantially as described we infringe, and there is an end of it; there is no need of saying anything about an "intermediate lever connection." If we do not use substantially the same device, we do not infringe, whether we use an "intermediate lever connection," or any other. Admitting, however, the right of the patentee thus to construe the claim it only makes our case the stronger; for it is very certain that whatever else we use, we do not use any "intermediate lever connection" whatever to combine the two sets of brakes. The patentees indeed assert the contrary, as their own construction of the patent of course drove them to do, but when the court comes to see the position they have here to assume, its entire absurdity will we think become apparent at once.

Cooper, their sole expert on this part of the case, at first says that he is "clearly of opinion that the *Stevens* patent *embodies the invention* claimed in the *Tanner;* all the brakes in the *Stevens* are applied by operating either windlass as in the *Tanner*, the center lever is dispensed with, for the reason that the power is applied directly to the brake levers, and by them is transmitted to the other truck; the brakes of the two trucks are connected by means of rods in such a manner that all that is performed by the *Tanner* is also accomplished by the *Stevens;* the difference is one of form and not of essence up to the point when the *Tanner* invention ceases, and the *Stevens* begins." p. 106.

But he is very careful not to tell us where that point may be found; if he had, we should have seen at once that it was an abstraction merely, an imaginary point incapable of any local habitation, and becoming a vanishing point the moment we try to seize it. So he tells us that the Stevens brake "*embodies* the Tanner invention," that most vague, plausible and convenient formula when one wishes to prove one thing to be an infringement of another, and does not know exactly how to do it. Being asked, however, on cross examination, to state his reasons, he at last comes out with this truly astounding statement, astounding even for an expert, that *the equivalent of the Tanner centre lever is to be found in the Stevens in one of the brake levers!*

Whatever may be thought of this ingenious theory, it has at least this merit, that it reduces the question of infringement to the briefest compass, and presents it in the most definite, tangible shape. What we had most to fear, in fact, the only thing we had to fear was that the matter might be left in the same vague, shadowy condition in which it was left by *Cooper* on his direct examination, and in which, as we have just seen, it was left by the court. The question now is simply this, Is the equivalent of the Tanner centre lever to be found in any one of the Stevens brake levers? We say as to this that it is not an equivalent; for it is combined and arranged in an entirely different way—it operates in an entirely different way—it was intended to produce and does produce entirely different results—it could not have been made without invention—it has never been pretended that it was a substitute well known at the date of the plaintiff's patent—in short it would be hard to find two things more totally unlike.

If we look now at the Tanner brake we shall find its parts combined as follows. The power is first communicated from the windlass by means of its rod and chain to one end of the centre lever A'. There the power is divided, part being sent back to the brake lever in the nearest truck, and the rest sent forward to the brake lever in the farther truck. There are thus five elements which serve to combine the windlasses with each other and the two sets of brakes; viz: the two rods running from the windlasses to the centre lever—the centre lever itself—and the two rods running from it to the brake levers. The centre lever is here, as said by Cooper, the "*controlling element.*" p. 116.

This centre lever is not a brake lever; it is not even a part of the brake mechanism proper; but a separate and distinct device, added to the brake mechanism for the sole purpose of receiving, transmitting and increasing the power. Or, as described and claimed in the patent, it is the means employed to connect the two sets of brakes. Or, to adopt the language of the patentees in their construction of the claim, it is the "intermediate lever connection." In whatever way we look at it, it is *an extra device outside of the brake levers.*

In the Stevens, on the contrary, the levers are all brake levers, and nothing but brake levers. They are all just alike. There are two in each truck, instead of one as in the old single brake and the Tanner; but this new lever is still as much a brake lever as the old one. It is not in any sense a centre lever. It is not an added device outside of the brakes; it is itself a part and parcel of those brakes. It is not the connection, but is itself a part of one of the things to be connected. It does not answer to the claim even as modified by the patentees, for it is not an "intermediate" lever connection. It is in no sense "intermediate" between the two sets of brakes, or between one set of brakes and the windlass.

But again, let us look at this brake lever if we can as something apart from the brakes, still it does not answer to the Tanner centre lever, for it does not connect the two sets of brakes, that is, it does not do the very thing the centre lever was designed for. It receives the power from the windlass, applies a part to its own pair of wheels and passes on the rest to the other lever in the same truck. It does not transmit any portion of the power to the other truck, for it is not connected with that truck. That has to be done by the other lever from which the long rod runs to the other truck. Thus it takes both the brake levers in one truck to connect the windlass with the other truck. And if the power is applied from the other end, all this is reversed; so that to make this pretended connection it takes sometimes the two levers in one truck and sometimes the two in the other. And in either case it takes *all four* of these levers to connect the two *windlasses*.

Again, the Tanner centre lever is pivoted to the bottom of the car, while the Stevens brake levers are hung each one to its own brake beam. This difference is very important.

1st. These two modes of attachment cannot be changed the one for the other. The centre lever would be wholly useless if hung to the brake beam, and so would the brake lever if pivoted to the bottom of the car.

2d. In the Tanner it may well be claimed that the *bottom of the car* is an essential element in the combination, while it is not so used in the Stevens.

3d. The centre lever being pivoted to the bottom of the car has but one motion, viz. a vibrating motion on its pivot; while the Stevens brake lever has three motions, viz. a vibrating motion on its pivot, a swivelling motion with the truck, and still a third motion with its brake beam, to and from the wheels; and all these motions are essential to its operation.

Again, the Stevens brake lever was not intended at all for the same purpose as the Tanner centre lever. These added levers in the Stevens were intended solely to remedy a serious defect that existed in the old single brake, and also in the Tanner. In both these brakes, owing to there being but one lever in the truck, far more power is applied to one set of wheels than to the other. Thus, suppose the upper arm of the lever to be twice as long as the lower, if now we apply a force of 100 pounds to the upper end we shall have a pressure of 200 pounds on one pair of wheels and 300 pounds on the other. Hence one pair of wheels will slide sooner than the other; and as it will not do to slide the wheels, we are compelled to apply much less force than if it were equally divided.

To remedy this defect Stevens added his second lever in each truck, and then combined the two by a short rod running from one lever to the same point in the other lever, thus obtaining an equal pressure on all the wheels in one truck. This was the first improvement made by Stevens, and was an improvement simply on the old single brake. It had nothing to do with the connection between the two sets of brakes; that had to be provided afterwards, and was provided by wholly different means, as we shall presently see.

Again, no one has ever said or dared to say that this brake lever of Stevens was a proper and well known substitute for the Tanner center lever at the date of the Tanner patent. Yet unless it was such a substitute, it was no infringement. The burden of proof too is here upon the plaintiff, he is bound to prove infringement, and he is bound of course to prove all that goes to make up that fact.

> "If the claim is valid defendants are not proved to have infringed it, for there is no evidence in the record tending to show that the contrivances used by defendants were at the date of the patent known substitutes for either of the means of adjustment described in the patent." *Tufts v. Boston Machine Co.*, 8 Off. Gaz. 240; Shepley, J., 1875.

Now there is not a word of such proof in this case, nor could there be. The brake lever as found in the Stevens never was known as a proper substitute for the centre lever; never was known at all in fact until long after the alleged invention of Batchelder & Thompson.

The differences above noted are special. We come now to a difference of a more general character, applicable not only to the comparison just made between the centre lever and the brake lever, but also to any broader comparison that may be made between the two machines.

The Tanner centre lever is pivoted to the bottom of the car by a bolt passing through the floor timbers, on which bolt the lever revolves. This bolt thus constitutes a rigid or fixed fulcrum for the centre lever, and it is to the existence of this fixed fulcrum that the chief merits and demerits of the Tanner brake are due. The court will see from the drawings, and still better by working the model, that this fulcrum furnishes the point of resistance against which the power of the windlass is exerted. Consequently by winding up the slack of the chain on one windlass we can apply the brakes without reference to the state of the other windlass. We do not pull against the other windlass at all, nor are we obliged to take up any of its chain. That chain may be entirely loose and yet the operation of the working windlass be entirely unaffected. Nay more, we may even disconnect the rods that run from the centre lever to the windlass and brakes at one end of the car, and yet apply the brakes at the other end the same as before, thus making of it one single brake. Or we may even leave out one windlass and the rod running from it; and thus have a double brake, but capable of being worked only from one end.

In the Stevens, on the contrary, there being no such fixed fulcrum, the point of resistance of the one windlass is only found in the other. The force runs way through from one windlass to the other, and has nothing to bring up on till it reaches the other. In other words the windlasses pull against each other, instead of pulling, as in the Tanner, against the fixed fulcrum of the centre lever. The Stevens is thus seen to be a unit in which every part is necessary to the operation of every other part. By connecting one of the brake levers on one car to the corresponding lever on the next car, all the brakes on both cars can be operated from one windlass; and so on through the whole train; only in practice there would be too much lost motion to make the brakes effective.

Now the advantages due to this novel arrangement in the *Stevens* are very great. It is owing largely to the absence of this fixed fulcrum that the *Stevens* brake has superseded the *Tanner* on so large a proportion of our roads. A brake should apply an equal pressure on all the wheels; not only in one truck, but in both trucks. If the pressure is unequal some of the wheels may slide, while on the others the brakes produce very little effect. But sliding the wheels is bad for two reasons; first it is apt to wear a flat place on the wheels (commonly called "spotting"), and second, a wheel when sliding is thought not to exert so much power towards stopping the train as just before sliding. Hence the best brake, other things being equal, will bring all the wheels as nearly as possible to the point of sliding at the same time. Now if all brakes could be perfectly adjusted, and remain so; if the rods and levers always remained of the same length and in the same relative position; if the wheels were perfectly round and true on their centres; and if the brake shoes always wore evenly; in short, if all the parts of the whole, complex machine, a heavy railroad train, and its trucks and brakes, could be kept in the right relation to each other while flying over the track at thirty miles an hour, and in spite of the repeated and violent strains upon them while being brought to rest, then one brake would be, so far as this matter is concerned, about as good as another. But this is not the case, the rods and levers will not remain the same; the turn buckles on the rods will wear loose and turn the wrong way, the trucks will shift their position according to the way the car is running, the break shoes will wear very unevenly; and the consequence is that a brake which is not self-adjustable may start out in the morning all right, and after running fifty miles or twenty, or even ten, may get so far out of order as to apply the power chiefly on one truck, or wholly on one truck and not at all on the other.

This is the one great defect in the *Tanner* brake, and it is due solely to this fixed fulcrum in the centre lever. It has no self adjustability. If the rod that runs from the centre lever to one truck happens to be a little shorter than the rod running to the other truck, the short rod will, of course, apply the brake on that truck, while the brakes in the other truck will remain loose; and the same thing will happen if the brakes' shoes in one truck wear faster than those in the other. The only help for this is to re-adjust the brake by hand.

In the *Stevens* brake on the contrary, there being no fixed fulcrum, the power is the same on both trucks, and remains the same in spite of the wearing of the shoes or the changes in the rods and trucks.

E. S. Renwick, one of patentee's experts, says "If the brake is in the best possible condition in each case, there is no appreciable difference between the two; but the *Hodge* arrangement permits of a considerable variation in the brake shoes and connections by wear and otherwise, without materially varying the equality of distribution between the two trucks; this difference in result being due to the fact that *in the Tanner system the fulcrum of the centre lever is fixed*, while in the *Hodge* brake the *fulcrums of the two cross levers are movable*, and adjust themselves to variations in the brake-shoes and in the connections." p. 945.

But the *Stevens* and the *Hodge* are both alike in this, neither having any fixed fulcrum; and both possess this advantage over the *Tanner*.

Waters, another of patentee's experts says: "The advantage of the Hodge over the Tanner consists in the fact that there is no relative adjustment to be maintained in the brake connections. The levers used in the Hodge contrivance between the windlasses and the brake levers *having no connection with the body of the car*, float into the position required, so as always to produce an equal strain upon each of the two trucks when the brakes are set up. This will not be the case in the *Tanner* brake unless the connection from the central lever to the truck levers are adjusted to a suitable length—the one with the other. In consequence of this difference, the *Hodge* brake will bear much greater neglect of adjustment than the *Tanner* brake." p. 716.

So the plaintiff's expert, *Cooper*, in trying to show that the *Millholland* brake differed substantially from the *Tanner*, says that there is no elasticity in the Millholland, "*all the pivots being rigid;* if a single shoe were worn or lost, all the force applied would be expended on a portion of the brakes, and in my opinion the brake could never be a practical one." "The chief defect in my opinion arises from the fact that the brake levers are also pivoted rigidly to the trucks; whereas in the *Tanner* they are suspended loosely from the truck, which gives an entire self-adjustibility to the latter. And if the brake (*Millholland*) were so adjusted, any unequal wear such as occurs constantly in railroad brakes, would throw it out of adjustment—throw all the strain on some of the wheels, and leave the others free." pp. 107, 108, 115.

Now this all-important advantage which according to *Cooper* the *Tanner* has over the *Millholland* in having no fixed fulcrum to *its brake levers*, the *Stevens* has over the *Tanner* in having no fixed fulcrum *between the trucks.* In other words, that self-adjustability which the *Tanner* has only as to the brakes in each truck by itself, the *Stevens* has in the trucks, and also between the trucks.

It is impossible to deny that this difference exists, or that it is material and substantial, for both these facts are proved by the plaintiff's own witnesses and also by the models. If then we should admit that all the parts in the *Tanner* were to be found in the *Stevens*, there would still be no infringement, for we must not only use the same elements, but those elements must be arranged and combined in the same way and so as to produce the same results.

The case of *Carver v. Hyde*, 16 Pet. 519, already cited, is here strikingly in point. The invention there was a new form of "*rib*, to be used in a cotton gin," and this "*rib*" had of course to be connected in some way with the other machinery. If we apply that decision to the present case, it will read as follows:

"The invention here in question is not an invention to be used by itself, but it is an improvement on the old brake, and that improvement consists in the means employed to effect the combination of the two sets of brakes; and it is to be used in connection with the other parts of a machine, viz., a railroad car, which has been long publicly known and used. This brake has in some way to be connected to the car: and the effect produced by it necessarily depends in a great degree upon the mode in which it is arranged and connected with the car and other parts of the machine. The patentees specify the mode, viz., the centre lever pivoted to the bottom of the car, and claim it as part of their invention. If then Stevens has by a lever of a substantially different form, *or differently arranged with the car, or not fastened at all to the car*, made an improvement which more effectually secured the object intended to be accomplished by the plaintiff's patent, it would be difficult to maintain that it could not be lawfully used because it produced the same result with the plaintiff's invention."

The argument of the patentees is that because the *Stevens* brake applies all the brakes at once by means, as they pretend, of an "intermediate lever connection," therefore it is an infringement, no matter what else may be added to it or taken from it. But this argument finds a complete answer in the case just cited. We do not admit that there is in the *Stevens* any lever connection, but if there is, it is too plain for proof that that lever is not fastened at all to the car; that it is arranged and combined in a totally different way, and attended by very different results.

There is another way of presenting this question of infringement in a very brief compass which yet makes it, if possible, still plainer than the last. It consists in showing how differently the two inventions were made. All that was done in the *Tanner* was to take the old single trucks and connect them by means of the centre lever. *Stevens* proceeded in a very different manner. He began at an entirely different point, and went on in an entirely different path. His first step was to add a second brake lever in each truck of the old single brake, for the purpose of equalizing the pressure on the wheels *in the truck*. He thus made his first improvement, an improvement, namely, on the old single brake. If now he had gone on to combine these two improved single brakes by the same means used in the *Tanner*, viz., a vibrating centre lever, it would have presented a very different question. In that case he would have had all there is in the *Tanner*, and this first improvement of his own besides. It would have been a clear case of addition. The court below might then well have said that the device "embodied the plaintiff's invention"—that *Stevens* had taken the inventive principle of the *Tanner* combination, and evolved something different and better by additional devices."

But this *Stevens* did not do. Having made this first improvement, he then went on to make another still more important. He might have retained the centre lever perfectly well, as the court can see at a glance from the handy model here offered in illustration. Fig. 8. But by so doing he would have lost the chief advantage of his brake over the *Tanner*. He therefore wisely rejected the center lever, and substituted the single straight rod which is the only thing that really connects his two sets of brakes. He could do this, though *Tanner* could not. By having two levers in each truck he was able, first to apply the power from the windlass to the brake levers in one truck, and then to transmit the power by his straight rod to the other truck. His second improvement thus sprang directly out of his first. His improvement in the old single brake enabled him to connect the two trucks in a far simpler and better way than was possible with the *Tanner*, in which the old single brake remained unchanged. And if anything can be plain, it is that this second or greater improvement was gained not by *adding* anything to the Tanner, but by putting his rod in place of the centre lever. It is a clear case of substitution.

This model, which we have called the "Tanner-Stevens" brake, shows also in another way how absurd it is to call the brake lever an equivalent of the centre lever. The brake levers in this model perform precisely the same function that they do in the Stevens brake. But it is clear that they do not here connect the two sets of brakes—that is done, as it is in the Tanner, by the centre lever. But if they do not connect the brakes in this model, neither do they in the Stevens.

We have thus far gone on the theory that the patent covers equivalents to the fullest extent, and have shown that even on that theory there is no infringement. But according to *McCormick v. Talcott*, 20 How. 404, they are not thus entitled to equivalents. The Tanner brake is admitted in the oath and patent to be an improvement on the old brake. The patentees, however, may perhaps claim that it was the first of its kind—that is, the first double acting brake, and therefore entitled to equivalents.

Supposing it to be the first of its kind, in what did the invention consist? The first railroad brake broke on only two wheels; the next step was to combine two of these brakes, so as to brake on four wheels, thus making what is now known as the old single brake, though really a double brake. Then two of these brakes were again combined, making the present double, or more correctly speaking, quadruple brake. This second improvement, therefore, was of the same sort as the first; it was only a second duplication.

But the Tanner was not the first double-acting brake. We leave out the *Nicholls*, *Millholland*, *Stanley-Talson* and *Camden & Amboy* brakes, and confine ourselves to those inventions the priority of which is admitted.

1. The *Griggs* brake, patented December 31, 1839, is disclaimed in the Tanner patent, and so are all other brakes which are operated by the movement of the cars. The *Griggs* broke on all eight wheels by mechanism connected with one of the axles, controlled by a clutch moved by the brakeman. We do not claim that either this or any of the "bumper" brakes was the same as the Tanner; but they were double brakes, and far better than the "bumper" brake described in Batchelder & Thompson's original application.

1018,
1038-1050.

2. The *Springfield* brake was first put upon two crate cars on the Western Road in 1843, and continued in use two summers, or as long as those crate cars were used. p. 145. It was again put on that road in 1856, as shown in Springfield brake No. 3, and used on all the cars, 23, in the mail train between New York and Boston, 16 months. p. 144.

In 1871, a car with the *Springfield* brake No. 2, and a car of the same build with the *Tanner* brake, were run in the same train for several months; this brake was then put on five cars, all in the train, and it was run for several months between New York and Albany, in alternation with a similar train with the *Hodge* brake. About the same time, similar experiments were tried on the Bos. & Prov., Bos. & Low., Conn. River, Prov. & Wor., and other roads, with Springfield brakes on the whole train, or with part Springfield, and part Tanner or Hodge.

A vast deal of testimony was taken on this point, which we should be glad to analyze at length, but we have not the space, nor can we think it necessary. We can only indicate its general nature. First, the two cars running in the same train, one with the *Springfield*, and one with the *Tanner* brake, wore out the iron brake shoes just alike, thus showing an equal friction on the wheels. Second, defendants' witnesses, p. 965–1174, brakemen, engineers, conductors, car-builders, and experts, over 50 in all, swear that the *Springfield* brake was as good or better than the *Tanner;* it stopped the train as quick; they whistled for down brakes at the same distances; they *never knew, without being told, whether they had on the one brake or the other.* Much of this evidence is very full and convincing. The patentee's witnesses swore, as usual, just the other way. The *Springfield* brake was not so good as the *Tanner;* it did not stop as quick, it was always getting out of order.

Now we admit that the *Springfield* brake is not the same as the *Tanner*, and does not defeat the *Tanner;* we admit that on very short curves, such as are sometimes found near depots and in cities, it does not work perfectly and is liable to be strained. But such curves are found on very few roads; as Adams states, not on the main line of any road. p. 984.

The same defect, though to a far greater extent, existed in the first sewing machine. It had its work stuck on pins, and hence could only sew on a fixed line. It was not so good on a curve as the Springfield brake. And yet it was never held an abandoned experiment, though it was an abandoned machine.

On the other hand, except on these very sharp curves, the *Springfield* brake is as good, and, as the evidence we think shows, even better than the *Tanner*. On a sharp curve it may not work so well; but neither does the *Stevens*. The patentees have shown that the *Stevens* on a curve is as bad as bad could be. "It stalls the horses, so that we have to disconnect the rods to get them through the city sometimes. And then the men get mad and tear the rods off, and the cars come through all the rest of the way without any brakes. This happens often and gives a great deal of trouble." p. 864, 869.

Nothing worse than this is anywhere said of the *Springfield* brake. The fact is that the trouble in both these cases was mainly owing to the very sharp curve which the cars had to pass in a city. That curve was so sharp that neither the *Stevens* nor *Springfield* brake could get round it without being strained, but this does not prove the latter brake to be worthless any more than the former. What it does prove is that the same advantage which the *Tanner* has over the *Springfield* brake on a curve, it also has over the *Stevens*. And in both cases this advantage is due to the same thing, viz., the centre lever, as is made plain by Waters. p. 710. Yet the *Stevens*, they say. is an infringement none the less.

Again, the *Springfield* brake, with all its defects, wore out just as many pounds of iron brake shoes as the *Tanner*. But this it could not do without producing the same friction on the wheels; and the same friction on the wheels must produce the same stops. p. 968 *et seq.*

3. But there is another Springfield brake about which there is no dispute. This is the *tender brake*, which has been in use on the Boston & Albany Road ever since 1841. p. 142–5. True, it can be operated only from one end, and in that respect is inferior to the *Tanner;* but it is none the less a double brake, and after a continued use of over thirty years may safely be called successful.

We submit therefore that the Tanner combination can claim equivalents to no greater extent than the *divider* combination in *McCormick v. Talcott;* but giving it the full benefit of equivalents the Stevens brake is still as far from being an infringement as ever.

IV.

THE DAMAGES.

We believe no case has ever come before this court in which the damages were so enormous as in this. By the master's report and the first final decree based upon it a total value was in effect put upon this patent of at least

SIXTY MILLIONS OF DOLLARS.

The way in which we get at this result is this: The master found the saving to be over $450 a car, per year. But according to the best authorities there was an average of 10,000 cars in the United States during the 20 years ending July 6, 1873. If then they all had had on the double brake, and had to pay at the rate fixed in this decree, the sum total would reach $90,000,000. It is true they did not all use the double brake during the whole period, but by far the greater part of them did. And if we include the freight cars on which the double brake is used, and which at least equal the number of passenger, baggage and express cars—there being no less than 3,000 of them on one road alone—

and the horse cars, we shall probably exceed the above calculation rather than fall below it.

After this final decree defendant asked leave to file a bill of review on the ground of newly discovered evidence, and at the same time urged upon the court some of the objections here made to the master's report. The motion was overruled, and with it all our objections; but the court struck off from its decree about $16,000, thus reducing the final amount to $47,725, at which the total value of the patent would be some forty or fifty millions, and the amount for which this defendant would be ultimately liable about $1,200,000. And there is a bill now pending against this defendant on the extension of this patent alone, in which the plaintiffs claim $800,000.00.

Now before coming to our specific objections we beg the Court to consider whether on this general statement alone this decree ought not to be set aside? Is this Court ready to affirm judicially that any patent is or can be worth fifty millions of dollars, or forty millions, or even twenty? Or will the Court establish such a precedent for the hundreds of other cases which if this is successful, are still to be tried?

If this were a thousand million, instead of fifty no one would think of arguing the matter. But it is hardly less certain with fifty millions than with a thousand. Or, if complainant had been able to include all the railroads of the country in a single suit, and had thus come here with a decree in his favor of fifty millions, then too no argument could have been required. Such a decree as that would have fallen by its own weight.

Again, if the roads have saved fifty millions by the *Tanner* brake they have saved at least ten millions more by the *Hodge* and *Stevens*, the value of the latter having been already fixed at $50 a car per year; they would save in the same time another fifty millions by the Westinghouse, and at least five millions by the Swage Block. Thus, according to the theory in this case the roads would save in 20 years from one to two hundred millions by these inventions alone. But a railroad is little more than a bundle of inventions, and every one of them can be shown by any necessary amount of evidence to save any necessary amount of money. If then we add to the above the patents on locomotives and all their various parts; boilers, flues, smoke stacks, grates, valves, cut-offs, and their innumerable connections—the passenger and sleeping cars—the wheels, axles, journals, boxes, couplings, platforms, springs, trucks, rails, switches, frogs, bridges, and so on, ad infinitum, and calculate the savings on each, we shall begin to understand what has so long been a puzzle to many, how the railroads in this country have all contrived to get so rich during the past twenty years!

But we all know that the railroads have not saved any such money. We all know that these calculations of the saving effected by new inventions are in the highest degree delusive. Hardly a week passes when we are not greeted with the news that somebody has invented a new improvement in the steam engine, for instance, by which you can save one-third or one quarter of the coal. We are incredulous—we ask for proof. We demand the figures, and the figures come at our call. They are all that could be wanted. Nay more, the machine is set to work before our eyes, the coal weighed to an ounce, the power estimated to a hair, and we see for ourselves that the saving claimed is effected. Another distinct improvement is shown, in the same way, and with equal certainty to save another quarter of the fuel. Do they both together save half? Do they both save a quarter? We all know they do not. We have all learned to make a large deduction from all such estimates. And yet it is these very estimates and far more than these that are too often imposed upon the courts as the sober truth.

In estimating these so called savings in this case, the master compared the *Tanner* with the *old single* brake, rejecting both forms of the *Springfield* brake, that is, the form used on the *crate cars* of the Western road in 1843 and '4, and the form used on the *tenders* of the same road from 1841 down to the present time, as adandoned and unsuccessful experiments. He found that for five years defendants ran constantly in passenger trains 24 cars, and required therefor 12 brakemen and four baggage men, equalling 16 brakemen; and that the use of the patent saved an equal number, that is 16. p. 37.

That on mixed trains they ran two cars, requiring one baggage man, equal to *one* brakeman, and saved *two* brakemen. On freight trains they ran two caboose cars, requiring two brakemen or conductors, and thus saved two brakemen. Making in all 20 brakemen saved. He called the wages of a brakeman $34.40 per month, making a total saving from this source of $41,280. That is he assumed that defendants could break the same number of wheels in the same time with the double brake that they could with twice as many men with the single brake.

In addition to this he found that the patent saved 2 sets of wheels per car per year; and that, after deducting the value of the old wheels, this left a saving of $22,358.40, which added to the saving by brakeman gave a total of $63,638.40, the amount of the first decree, or a little over $450 per car per year; equal, as we have just seen, to $60,000,000.00, for the whole patent, on the most moderate calculation. It is true that the court has reduced this finding some $16,000, but at the same time expressly overruled all our exceptions, thus unqualifiedly approving of the method adopted by the master. These errors then all remain, in kind, if not in degree; and still work very great injustice to the appellant. These errors began early.

I. The interlocutory decree of July 18, 1871, directs the master to compute, not only the defendant's profits, but, in addition thereto, the complainant's damages. p. 35. The decree was so drawn, probably under the impression that the case was governed by the law of 1870, Section 55. But that law has no application. The repealing clause and schedule, Section 111, expressly limit the *remedial* provisions of this act to suits thereafter to be commenced. It may be said, however, that defendants are not prejudiced, because the master has found the damages in this instance to be the same thing as the profits.

To this we reply, first, that the decree is not simply an erroneous finding as to the *facts*, but it entirely mistakes and misapplies the *law*. But, secondly, it is impossible to say that defendants have not been damnified. There were many nice questions for the master to settle; and we cannot tell how far his doubts may have been resolved in favor of complainant by the thought that he was entitled to something more than mere profits. The master should not be subjected to such a bias, nor the defendant to such a risk. And in such a case it must be shown beyond doubt that the error neither did nor could have worked the party any prejudice. *Deery v. Cray*, 5 Wall. 795.

II. The master erred in finding the Springfield brake an unsuccessful and abandoned experiment, and on that ground excluding it from his calculations. We have already argued this question at p. 78 of this brief, and only repeat here that a brake which has been used constantly for the last thirty years can in no sense be deemed an experiment, still less unsuccessful or abandoned. Nor can those terms with any more propriety be applied to the other Springfield brake which was used on the *crate cars* for part of two years, and as long as those cars themselves continued to be so used. Nor can a brake be called unsuccessful which is admitted to do good work on a straight track, or on a short car, simply because it did not work so well as some others on a curved track or on a long car.

III. But, admitting that the master was right in adopting the single brake as his standard, we still say that his method was erroneous, not only as to the facts but also as to the law.

The savings here were found to be of two kinds, the saving of brakemen, and the saving of wheels. We will consider first,

THE SAVING OF BRAKEMEN.

The master has found that defendants saved as many brakemen as they employed, on the assumption that they must have had twice as many men with the single as they actually had with the double brake. Only on the mixed train he has, for some unknown reason, found that they saved *twice as many* as they employed. And he has found that they have thus saved the wages of all these men; and that they are chargeable with the full amount of these wages as profits. We expect to show that this finding and the assumption on which it was based are both alike fallacious—that defendants never have saved a single man by the use of the double brake—that still less have they saved as many as they employed—that consequently they have not saved the wages of these men—and finally, even if they had saved all these wages, that those wages would not in any proper sense represent defendant's profits.

And first, we deny that defendants have ever saved a single brakeman by use of the double brake. On the contrary, it has been, like the Westinghouse brake, the Miller platform and coupler, and many other similar inventions, simply an added expense. It is not pretended that the defendants in this case actually did employ twice as many brakemen with the single brake as they did with the double. The evidence is conclusive that they continued to use precisely the same number. The only evidence on this point as to defendant's road is that of Garvin. p. 962, and he swears that he had been in the employ of the Concord & Nashua, the Northern New Hampshire, the Vermont Central, and *the Chicago & Northwestern; and that on all these roads they used just as many brakemen with the double as with the single brake.*

What other roads did is not important, but the evidence shows that the same was true in regard to them. See dep'ns of Hayes, p. 960; Burton, p. 906; Hutton, p. 910; Van Syckle, p. 510; Elder, p. 921.

Now if defendants had in fact diminished the number of their brakemen in consequence of the double brake, then we admit they might have been chargeable with *a part* of that saving; but as they never did diminish the number, we say that there could not possibly have been any saving in that direction, and whatever saving there may have been must be sought for somewhere else. What then is the saving by the use of the double brake? Simply this: the saving of time. That is, using the same number of brakemen as before, the cars can be stopped a little sooner. That this advantage has been vastly overrated we think there is no doubt. It has been quietly taken for granted that a train could be stopped with the double brake in half the time required for the single. But a moment's thought will show that this, like a thousand other merely theoretical notions, is entirely a mistake. There are many other forces at work to bring a train of cars to rest besides the brakes. The inequalities in the track, both lateral and vertical; the curves, the joints between the rails, the friction on all the axles, even the resistance of the atmosphere, all combine to bring about this result—and every one of these forces is of course just as active with the single brake as with the double.

Owing to these and perhaps other causes that have not yet been explained, it is far from being true that a train can be stopped twice as quick with the double as with the single brake. On the contrary, the experiments tried for this purpose show that there is really very little difference between them. These experiments were made in November, 1871, and proved that a train can be stopped by the single brake very nearly as quick as with the Tanner. See dep'ns of Hitchcock, p. 1075-6; Adams, p. 982, and Stearns, p. 1086-7.

But admit that the double brake will stop the train nearly twice as quick as the single, that does not prove any saving in brakemen. It is still a saving in time only, and it is for that time if anything, that defendant ought to pay. A simple illustration will make this perfectly plain. Suppose a patent for an improvement in wagons by which one horse can draw as much as two without it. A, the infringer, still drives his two horses, and he carries no heavier load. Has he saved one horse, or must he pay the same as if he had? It is clear that thus far he has saved nothing except that it is easier for his horses. But now suppose he drives a little faster—as the improvement would enable him to do—and thus saves a little time; here we have a clear saving from the use of the invention, a saving that he ought fairly to pay for, that is if it should prove capable of estimation. But nothing can be clearer than that he has not saved either of his horses. To put it in a different shape, if he does not use the improvement at all of course he cannot be made to pay for it. And if he does use it, but uses it in such a way as not to gain the advantage promised, that is, a saving in horses, but so as to gain a different advantage, that is a saving in time, it seems equally clear that whatever profits he is liable for in a court of equity cannot be based on any speculative saving of horses which he has not saved, but must be awarded, if awarded at all, for the sole benefit he has derived from the invention, viz., the saving of time.

The appellee's argument here is that defendants found it *necessary* for the safe running of their trains to have brakemen enough to apply the brakes to a certain number of wheels; that this would have been equally necessary with the single brake, and hence they *must* have had twice as many men.

There are several answers to this, every one of which seems to us conclusive. First, whether necessary or not, no railroad ever did in fact do any such thing. No railroad ever did employ twice as many men with the single as with the double brake, and of course no road ever found it necessary to do so. This so called necessity therefore is a coinage of the patentee's own brain.

Second. Whether a thing is necessary or not depends often, if not always, on what it costs. A prudent railroad manager might well consider a device a necessity provided its advantages outweighed the increased expense. Thus it is a necessity to have a guard rail in the centre of the track on bridges, but it is not a necessity to have it on the whole road, though it would be very desirable to do so, for the simple reason that no road can possibly afford it. But if in some way the cost of such a rail could be largely reduced, then it might become a necessity over the whole line of the road. So with the brakes; it may be thought by some one railroad official a necessity to apply the brakes to at least half the wheels in a train, provided it can be done at not too great a cost; but if he has got to pay at the rate of three hundred dollars a car a year for the increased braking, he would at once say, "We cannot afford it."

Again, the court is familiar with the bit known as the "curb" by which one man can with ease curb the most fractious horse. In fact it is much easier for one man to check a horse with this bit than for two with the old bit. Then, according to appellee's argument, the use of the curb would save the wages of at least one man, because in order to do with the old bit what one man can do with the curb, would require two men. And if the user of the curb should admit that he found it necessary to use it, that he should not consider it safe to do without it, it would follow that if he had continued to use the old bit, he must and would have employed two men to hold his horse. This argument of "*necessity*" is just as good in this case as in the case of the brakes.

Third. This speculation as to what defendants might and might not have done is all idle. As this court has so often decided, the defendant is never liable for any mere speculative profits, but only for his actual profits. He is not liable for what he might have made, nor even for what he ought to have made, but solely for what he did make. Appellee has here been driven to use a very singular illustration. He said in the court below,

> "As well might it be said that the modern weaver's loom—for instance the hair cloth loom—saves no labor, though at least one hundred looms can now be tended by the same number of girls which were formerly required to tend fifty. Apply the counsel's argument to this, and it would be that the mill owner who increases his looms from fifty to one hundred saved no attendants, because he still employed as many as when he had only fifty looms. But with the same labor he has doubled his product; doubling the product with the same labor is equivalent to the same product with half the labor. This is the case with defendants. Assume they do still employ the same force of brakemen—they have more than doubled the wheels "braked" by that "force."

That this argument is fallacious, that it has no application to the present case, will become apparent at a glance. The mill owner who doubles his looms of course doubles his products; he can make two yards of cloth where before he made only one. And if he sells his cloth at the same price he of course increases his profits by a sum equal to the diminished cost of production. But the railroad receives no such products from its brakes, it has nothing more to sell; no more money comes into its coffers. If the railroad received a certain sum of money, say five dollars, for every additional wheel, then we admit the cases would be parallel. To put this in another way. The mill owner has fifty girls, and the railroad has fifty brakemen. Then certain improvements are made by which the girls and the brakemen can both do twice as much work as they could before. But neither the mill owner nor the railroad makes any change in the number of their servants. Then what happens? At the end of the year the millowner has sold twice the quantity of cloth without paying out any more wages than before. The railroad has paid out no more wages and it has paid out no less. But it has no more cloth, and no more of anything than it would have had with the old brake, and of course it has made no profits. It has simply incurred the increased expense of the new brake. It has absolutely nothing to show for it; nothing that could be set down on the credit side of its brake account, according to any system of book-keeping we ever heard of.

The appellee says further that defendants never used the single brake, and he argues this at length as if it were a matter of importance. It is but a small part of defendants' road included in this suit, and what they used on the other parts we only know from the testimony of Garvin, already quoted. That shows that they used the same number of men with the double as with the single brake.

But admit the appellee to be correct in his assertion, that only makes the matter worse; for if defendant never used the single brake, how is he to tell how many brakemen they would have used with it. It is clear that in that case the whole thing would have to be left to conjecture and speculation, even more than it is now.

To re-state then our proposition in more general terms, we insist that unless the user of a patented device has actually made money by it, he is not liable for any profits. We do not mean by this of course that he must have *received* more money; it is the same if he has *saved* it. But the saving must be real, not fanciful. And it will not do to argue that *if* he had used the old machine in a different way, in a way that no one ever did use it, in a way that no one ever would use it, he would have saved so much money. The plaintiff is here suing in equity, he has elected to claim defendants' profits, and he must take whatever profits were actually made.

But secondly, admitting that defendants did save any brakemen by the double brake, we deny that they saved as many as they employed with the double. The master has found that defendants employed 16 men on 24 cars, and that they therefore saved 16. If then they had happened to employ only 10 men they would have saved only 10; and so, if they had employed 24 men they would have saved 24. We thus reach this strange conclusion, that the more men to a car a road has employed with this double brake, the more it has saved. That is, the more one spends the more he has. If anything more were needed to show the utter unreasonableness of this whole theory of profits, its purely visionary character, we have it here. For there is evidently no other way by which to estimate this supposed saving of brakemen than just this. If defendant did in fact save any men, they saved a number equal to that which they employed with the double brake. But that they could not possibly have saved that number; that such a method of estimating the number leads at once to the grossest absurdity, is fully demonstrated by the above illustration.

Again, the master has found that defendants employed 12 brakemen and 4 baggagemen, on 24 cars, with the double brake; and that they would have had twice as many with the single. That is they would have had 24 brakemen and 8 *baggagemen*. But there would have been no more baggage with one brake than with the other, and of course no need of any more baggagemen. The four extra men, therefore, having nothing to do with the baggage, would have been more than the equivalent of the four whose first and principal duty it was to look after the baggage. It is absurd therefore to suppose that any road would have doubled its baggagemen simply to gain their services as brakemen. And this leads us to suggest what may perhaps be a partial explanation of the error into which the master has fallen. He has assumed that the brakemen did nothing but brake, whereas this was a small part of their duties. They were required to take care of the fire and lights, to call out the names of the stopping places, to assist passengers on and off the cars; and generally to help in running the train.

The court below asked: "Suppose a brake by which the engineer could brake all the wheels at one and the same moment, would not that save all the brakemen?" And the answer is, we have just such a brake already, the "Westinghouse," by which the brakes of a train are more completely under the control of the engineer than the brakes of a single car are under the control of the brakeman. By a turn of his hand he can apply all the brakes in an instant. He can graduate the pressure with greater nicety than any hand brake in existence. He can stop the train with a suddenness never before known. And what was not anticipated, even by the inventor, the pressure is applied first, just where it ought to be, to the rear car of the train, and then to every other car, in order; thus preventing their running on each others heels. In short, it is the very perfection of a brake; and, if any brake ever *could* save all the brakemen, this ought to do it. According to the *theory* adopted in this case, it *would* save all the brakemen. But we all know it does no such thing. We have all ridden, time and again, on trains furnished with this brake, but we have never ridden without brakemen; and we probably never shall. Waters' Dep, p. 705.

According, then, to the theory in this case, the users of the Westinghouse would have to pay for as many more men as would be necessary to do with the hand brake what is done by the Westinghouse; that is, not merely double the number, but four, six, ten times the number, according to the size of the train; because, with this brake, one man can do the same work for ten cars that ten men can do with the hand brake, and do it much better, too; thus fixing the savings by the Westinghouse brake as at least seventy millions more, while all the time the fact is that railroads employ, as a general rule, the same number of brakemen with the Westinghouse as they did without it.

An illustration or two will make these points still plainer. Some years ago, a man invented a device by which it was said the sails of a ship could be handled by one-third the number of men required before. Then, according to this case, the users of that device would save two-thirds of their sailors, and of course would be chargeable with their wages. Or to take the curious modification of this rule adopted in this case, if they continued to use the same number of sailors after introducing the device that they did before, they would have to pay for twice that number, as for so many men saved by this wonderful invention. That is, if the crew at first consisted of twenty men, and if after adopting the device they still employed twenty, they would have to pay the patentee the wages of forty men. Why? Because—as found in this case—sixty men without the new invention would be only equal to twenty with it!

Again. A, we will suppose, has three servants a part of whose duties is to carry up coals for the fires. By using an elevator one man can carry up as much as two without it. A, however still keeps his three servants, but on being sued for infringement on the elevator it is found by the master that he has saved the wages of an equal number, because one man with the elevator is equal to two without it! We can think of nothing quite equal to this legerdemain except the Irishman's stoves of which we have all heard, one of which saved half of the fuel, while two saved the whole.

It seems to us that enough has now been said to show that this alleged saving of brakemen has no existence in fact, that it is not merely speculative, but visionary, that to assume otherwise is to assume not only what is not supported by the proof, but what is directly contrary to the proof. It has betrayed the master and the judge into awarding an amount of profits that dwarfs all preceding awards into insignificance; an amount so startling and overwhelming that one would naturally suppose they would have sought some means to diminish it; that they would have sought diligently until they found it. On the contrary, not satisfied with this enormous profit based on the fictitious saving of brakemen, they then went on to add half as much more for what was curiously enough claimed to be

The Saving in Wheels.

The master's report on this part of the case was as follows: Defendants used what was equal to 29 cars for one year, and 27 cars for each of the other four years. The patent saved two sets of wheels per car per year, making 274 sets in the five years.

The cost of a set of wheels was	$ 133	60
Cost of putting on a set	8	00
Total cost of a set	$141	60
Or for the whole 274 sets	$ 38,798	40
Value of old wheels for old iron	16,440	00
Leaving as actual saving	$22,358	40

This was on the theory that the double brake did not slide the wheels so much as the single, so as to wear flat spots upon them. Applying to this result a similar calculation to that made as to the brakemen, we find that the railroads have saved by the use of the double brake, during the 20 years covered by the patent, some twenty million dollars worth of wheels, or an amount so vast as to be not merely improbable but wholly impossible, and such as at once to make out a *prima facie* case against the patentee. The evidence to overcome this presumption, and by which this prodigious saving is made out, is of the most unsatisfactory sort. We find no fault with the witnesses; but simply with their means of knowledge, and the imperfect character of their statements. Most of this testimony is what may fairly be called guesswork. The witnesses have an idea, a notion, that the wheels were not changed so often after they got double brakes as they were before. And they *think* that they saved one, two or three sets of wheels a year. One witness gives his impression, and the next thinks that is about right. Again, none of these tell us anything of the conditions under which this comparison was made. We have no means of knowing how much of this apparent saving was due to a difference in the quality of the wheels, whether good iron or bad, with chilled tires or without, of iron or steel, or in the weight of the cars, or in the condition of the track, or the increased care or efficiency of the men. We know that the tracks generally became smoother, and that the brakemen gradually acquired greater skill and experience; and that they found out that sliding the wheels not only injured them, but would not stop the train as well as when they were not sliding. The substitution of iron for wooden shoes may also have had something to do with it, as the wood would take hold of the wheel, and thus prevent its turning, more than the iron.

It is very certain that there is no more need of sliding the wheels with the single brake than with the *Tanner*. The increased leverage in the Tanner, in fact, enables the brakeman to put more force on each wheel than can be done with the single brake. See Dep. of E. S. Renwick, one of patentee's experts, p. 942, Int. 18, and p. 944, Int. 6. It is equally certain that by properly graduating the leverage in the single brake, the danger of sliding the wheels could be so far diminished as to go for nothing. And even without that, a little more care on the part of the brakemen is all that would be necessary to remedy this supposed evil. There is not the slightest justice therefore in crediting this vast saving to the double brake.

But, in the second place, it is not so important what was done on these other roads as what was done on defendants' road. A single set of wheels did not last a year on defendants' road with the *Stevens* brake. On the contrary it is stipulated that they changed their wheels as often as once or twice a year, sometimes oftener. p. 850. And *Gunther*, patentee's witness, swears that they changed them "every four months, about, on an average." p. 860. That is, instead of one set of wheels lasting a year with the double brake, the defendants actually had to change them three times a year. Yet the master has charged defendants with two sets of wheels saved a year, on the theory that one set would last a year with the double brake.

The next error, however, is still more glaring. In this comparison between the wearing of wheels with the single and double brakes the same number of brakemen was employed with each. Not one of the witnesses testifies to observation or experiment, where the number of brakemen employed with the single brake was double that employed with the double brake. They could not swear to that, for the simple reason that, as we have already seen, no road ever did in fact employ twice the number of men. If then we admit that with *two* men to a train of six cars the wheels would slide so much more with the single brake than with the double, it by no means follows that this would be the case if the single brake had *four* men to the train. It may be that with only two men their natural hurry and impatience, and their inability to put the brakes on more than half the number of wheels, would lead them to overdo the matter, and apply more than the needful pressure on the wheels they did brake. But if there had been four men, knowing that they could brake twice the number of wheels, knowing that they had plenty of time, there would be no need of any of this hurry or impatience. They would be very nearly the same as two men with the double brake. And certainly there is no reason or justice in assuming that four men with the single brake would slide the wheels just as much as two men. Yet this is what was done by the court below. The court first charged defendants $40,000, for brakemen, on the theory that they must have employed *twice* the number with the single brake; and then charged them $20,000 more, for wheels, on the theory that they would have employed only the *same* number. Defendants are thus made to pay twice over for the same thing. To the first amount already so enormous, the court has added half as much more, and without any evidence to justify it.

Appellee will reply to this that the number of brakemen makes no difference, that sliding the wheels is a vice inherent in the single brake; and that a man putting all his strength upon only four wheels is more likely to slide them than if that strength were divided among eight. But according to appellee's own testimony, just quoted, the same man can apply more force to each one of the eight wheels with the *Tanner* brake than he can to each of the four wheels with the single brake. If then he applies all his strength he will be more likely to slide the wheels with the *Tanner* brake than with the single. If in fact he does not so often slide the wheels, it is because with the double brake he has more control over the train, and so does not need to slide them, or to run the risk of sliding them. Braking, as he does, on all eight wheels, he does not need to overdo the matter, or to impose more than their fair share of duty on any four. So if there were a man at each end of the car with the single brake, they would in like manner control the train, and would not need or feel tempted, as a single man might do, to apply so much force as to run the risk of sliding.

The burden of proof is here upon the plaintiff. He must prove beyond a reasonable doubt that with a man at each end of the car the single brake would still slide the wheels just as badly as with a man only at one end. Mere theorizing here will not do. The defendants insist that two brakemen with the single brake are the same as one with the double; that having paid for this extra man he belongs to them, and that they ought not to be made to pay for him over again under another name.

Renwick, the plaintiff's expert, when asked to what the alleged difference as to this sliding of wheels was due, replied: "In my opinion it is due to two causes, viz.: first, that where the single brake has been used *there have not been a sufficient number of brake shoes put in operation to stop the train in the time permitted for the purpose;* and second, that when the single brake was used, a brakeman could only operate simultaneously upon half the number of shoes that he can when double brakes are used." p. 946.

Of course, then, if twice as many brakemen were employed, this first reason could no longer exist. But he says further: "So far as the mere stopping of the train is concerned, I do not know that there would be any great difference between the effect with the single brake and the double brake—assuming that brakemen enough were used with the single brake to put the same number of brake shoes in operation as were put in operation when the double brakes were used."

And yet, in the face of this admission. the court below has found that even with this increased number of brakemen the wheels would slide as badly as ever. We admit, of course, that the wheels would sometimes slide with the single brake, even with a man at each end of the car, but so they do with the double brake. The question, however, is not whether they would sometimes slide, nor even whether they would often slide, but whether they would slide as often with the two men as with one. The evidence on this point is all theoretical, none of the witnesses testifying from actual experience; but when the plaintiffs' expert gives it as his opinion that this difference in sliding is in part at least due to the fact that a sufficient number of brake shoes have not been put in operation, we cannot see how the court below was justified in assuming that his opinion was erroneous. The doubt here, if any, is to be determined in favor of the claimants. It is the plaintiffs duty to furnish the court with the "proper data for a calculation of his damage, and not expect the court to work out the result for him, by inferences or presumptions founded on such subtle theories." *New York v. Ransom*, 23 How. 491.

We say, then, as to this supposed saving of wheels, that it is largely fanciful and fictitious, even when comparing the double brake with the single brake, *with the same number of men*. But we say further that it is not fair to make the comparison in that way, but that the court having calculated the saving of brakemen on the theory that we *must have used twice the number of men*, we are entitled to the full benefit of that increased number when we come to estimate this supposed saving of wheels.

Finally, let us suppose that a certain saving, either in wheels or brakemen or both, has resulted from the use of the *Stevens* brake, we still deny that this saving at all represents the profits of defendants. Thus a volume of law reports can be printed for two dollars. But to do the same work by hand, and not nearly so well, would cost a hundred. Is the user of the press therefore going to pay the patentee ninety-eight dollars for every volume sold, when he himself only receives five? Or to put it in another way, one man can do with the press as much as a hundred without it. Has the user of a press therefore saved the wages of the ninety-nine? According to the rule of this case he has, and is bound to pay that much to the patentee. That is, he is bound to pay as profits a sum vastly in excess of the gross receipts of his business. Again, the carved legs of a common chair or table can be turned in a lathe at the cost of a few cents, while to do the same work by hand would cost a dollar. But it would be strange law, to say nothing of equity, that should award to the patentee of the lathe the 95 cents thus saved on each table leg, when all the defendant had received was five cents. So with Whitney's cotton gin. The value of the labor saved by that invention exceeded the total value of the cotton, but the user of the gin could not be charged wheels they did brake. But if there had been four men, knowing that they could brake twice the number of wheels, knowing that they had plenty of time, there would be no need of any of this hurry or impatience. They would be very nearly the same as two men with the double brake. And certainly there is no reason or justice in assuming that four men with the single brake would slide the wheels just as much as two men. Yet this is what was done by the court below. The court first charged defendants $40,000, for brakemen, on the theory that they must have employed *twice* the number with the single brake; and then charged them $20,000 more, for wheels, on the theory that they would have employed only the *same* number. Defendants are thus made to pay twice over for the same thing. To the first amount already so enormous, the court has added half as much more, and without any evidence to justify it.

Appellee will reply to this that the number of brakemen makes no difference, that sliding the wheels is a vice inherent in the single brake; and that a man putting all his strength upon only four wheels is more likely to slide them than if that strength were divided among eight. But according to appellee's own testimony, just quoted, the same man can apply more force to each one of the eight wheels with the *Tanner* brake than he can to each of the four wheels with the single brake. If then he applies all his strength he will be more likely to slide the wheels with the *Tanner* brake than with the single. If in fact he does not so often slide the wheels, it is because with the double brake he has more control over the train, and so does not need to slide them, or to run the risk of sliding them. Braking, as he does, on all eight wheels, he does not need to overdo the matter, or to impose more than their fair share of duty on any four. So if there were a man at each end of the car with the single brake, they would in like manner control the train, and would not need or feel tempted, as a single man might do, to apply so much force as to run the risk of sliding.

The burden of proof is here upon the plaintiff. He must prove beyond a reasonable doubt that with a man at each end of the car the single brake would still slide the wheels just as badly as with a man only at one end. Mere theorizing here will not do. The defendants insist that two brakemen with the single brake are the same as one with the double; that having paid for this extra man he belongs to them, and that they ought not to be made to pay for him over again under another name.

Renwick, the plaintiff's expert, when asked to what the alleged difference as to this sliding of wheels was due, replied: "In my opinion it is due to two causes, viz.: first, that where the single brake has been used *there have not been a sufficient number of brake shoes put in operation to stop the train in the time permitted for the purpose;* and second, that when the single brake was used, a brakeman could only operate simultaneously upon half the number of shoes that he can when double brakes are used." p. 946.

Of course, then, if twice as many brakemen were employed, this first reason could no longer exist. But he says further: "So far as the mere stopping of the train is concerned, I do not know that there would be any great difference between the effect with the single brake and the double brake—assuming that brakemen enough were used with the single brake to put the same number of brake shoes in operation as were put in operation when the double brakes were used."

And yet, in the face of this admission. the court below has found that even with this increased number of brakemen the wheels would slide as badly as ever. We admit, of course, that the wheels would sometimes slide with the single brake, even with a man at each end of the car, but so they do with the double brake. The question, however, is not whether they would sometimes slide, nor even whether they would often slide, but whether they would slide as often with the two men as with one. The evidence on this point is all theoretical, none of the witnesses testifying from actual experience; but when the plaintiffs' expert gives it as his opinion that this difference in sliding is in part at least due to the fact that a sufficient number of brake shoes have not been put in operation, we cannot see how the court below was justified in assuming that his opinion was erroneous. The doubt here, if any, is to be determined in favor of the claimants. It is the plaintiffs duty to furnish the court with the "proper data for a calculation of his damage, and not expect the court to work out the result for him, by inferences or presumptions founded on such subtle theories." *New York v. Ransom*, 23 How. 491.

We say, then, as to this supposed saving of wheels, that it is largely fanciful and fictitious, even when comparing the double brake with the single brake, *with the same number of men*. But we say further that it is not fair to make the comparison in that way, but that the court having calculated the saving of brakemen on the theory that we *must have used twice the number of men*, we are entitled to the full benefit of that increased number when we come to estimate this supposed saving of wheels.

Finally, let us suppose that a certain saving, either in wheels or brakemen or both, has resulted from the use of the *Stevens* brake, we still deny that this saving at all represents the profits of defendants. Thus a volume of law reports can be printed for two dollars. But to do the same work by hand, and not nearly so well, would cost a hundred. Is the user of the press therefore going to pay the patentee ninety-eight dollars for every volume sold, when he himself only receives five? Or to put it in another way, one man can do with the press as much as a hundred without it. Has the user of a press therefore saved the wages of the ninety-nine? According to the rule of this case he has, and is bound to pay that much to the patentee. That is, he is bound to pay as profits a sum vastly in excess of the gross receipts of his business. Again, the carved legs of a common chair or table can be turned in a lathe at the cost of a few cents, while to do the same work by hand would cost a dollar. But it would be strange law, to say nothing of equity, that should award to the patentee of the lathe the 95 cents thus saved on each table leg, when all the defendant had received was five cents. So with Whitney's cotton gin. The value of the labor saved by that invention exceeded the total value of the cotton, but the user of the gin could not be charged with this saving, for the whole amount received by him for his cotton would not begin to equal it. The same is true of the pin-making machine, and the sewing machine, and of all other labor saving machines. They undoubtedly save labor, but it is a mistake to suppose that this saving represents as a general rule, the profits of the user. If he is the first to use the new machine, and is thus able to *sell at the old prices*, while saving half or two-thirds the cost of production, of course in that case the saving effected by the invention does exactly represent his profits from it. But this seldom happens, and when it does, only for a short time. Competition soon puts down the price to a sum corresponding to the diminished cost of production, and then it is the public, and not the user of the machine that gets the benefit of the saving.

Of the correctness of the above principle there can be no doubt, and there is no reason why it should not be applied in all cases at least where the length of use and the magnitude of the estimated profits demand it—as they clearly do in the present case. It may be thought, however, that this principle has here no application because the defendant is a railroad. and does not sell its brakes or the products of them. But it applies to a railroad just as much as to any other defendant, and even more; for there is no other class of business where competition is so keen, or where prices are so constantly kept down, both by this competition and by the public demand. The only difficulty attending this part of the case is in showing that this particular invention comes within the principle now under discussion. From the very nature of the case it is not easy to show that the railroads have reduced their rates in consequence of the saving effected by the double brake. Yet that they have made such reduction is we think capable of being shown, especially if the saving from this brake makes any approach to the amount above suggested. Thus it costs only a dollar to carry a barrel of flour from Chicago to New York by rail, while it would cost at least twenty dollars by wagon. Suppose then that one could have a patent on the whole railroad, could he recover of an infringer nineteen dollars as the saving on every barrel transported? Clearly not, for the infringer has only been paid a dollar, and of course cannot have saved the nineteen. But what is true of the railroad as a whole is true of its parts. The whole railroad is but an aggregate of inventions. The greater part of them are money saving inventions, some doing more in this way and some less; and it is solely owing to this fact that the railroad is able to carry so much cheaper than the wagon. But the savings effected by all these inventions evidently are not retained by the railroad; for, to do that, the railroad would have to charge just as much as the wagon. But if it did charge as much as the wagon for carrying freight, it would have very little freight to carry, and would thus require fewer cars and fewer brakes.

That is to say, in every one of these cases, the printed book, the legs of the table, the cotton gin, and the railroad, it is impossible for the user of the invention to obtain a profit which shall make any approach to the nominal saving. If indeed he could still sell the products of the invention at the old price, if he could sell his printed book at the same price as the manuscript, if he could sell his table legs turned in a lathe at the same price as when made by hand, if the railroad could charge the same price for transportation as was formerly charged by the wagoner, then we admit that the difference in the cost of production would fairly represent the savings. But we all know this to be impossible. We all know that it is only on account of their greatly diminished price that these articles can be sold in such greatly increased quantities.

AND IT IS EVIDENTLY UNFAIR TO GIVE TO THE PATENTEE THE SAME PROFIT ON THESE WHOLESALE SALES AT THE DIMINISHED PRICE THAT HE WOULD BE ENTITLED TO ON THE VERY SMALL NUMBER OF SALES THAT COULD BE MADE AT THE ORIGINAL PRICE.

Thus in the Mowry wheel case, if by the use of that process the infringer saved one dollar a wheel, and sold a hundred thousand wheels *at the old price*, he might justly be charged with a hundred thousand dollars; but if in order to sell that number he had to lower his price half a dollar a wheel, it is evident that his actual profits have been just so much diminished, and that fifty thousand dollars would be all he ought to pay. In that case the patentee gains whatever advantage may be due to the increased number of wheels sold, and of course ought not to claim the profit *on each wheel* that could only have been obtained, if obtained at all, by the sale of a smaller number at the higher price.

We insist then with full confidence that even if the railroads have in one sense saved $350 a car a year by the double brake, they cannot justly be charged that for every car, because in order to do their increased business they have had to charge reduced rates, and because the patentee receives his full equivalent for his loss of profits on any one car from the great increase in the number of cars which the lower rates alone render necessary or even possible. To this the plaintiff replied as follows:

"In conclusion upon this point it may be said in answer to the argument that a railroad is compelled constantly to reduce its rates and thus to share with the public the benefit of every invention, that the presumption of common sense is that if it does reduce its rates it will thereby obtain more business and make more money. In any trade the subject of which is in constant demand—as railroad transportation is—reduction of price irresistably produces increase of traffic. Therefore, though there may be less profit on each individual transaction, the greater volume of transactions makes the aggregate profit much larger. A glance at the report of almost any sound legitimate railroad enterprise will show that this is especially true of that class of business. The road may charge each passenger less fare, but it transports so many more passengers in consequence that its receipts are enormously increased. The latest report of the Chicago and Northwestern R. W. Co. strikingly illustrates this. It states that during the last fiscal year it carried 2,479,202 passengers, against 2,224,705 the preceding year—being an increase of $11\frac{44}{100}$ per cent., while the receipts per passenger were decreased only 3 [illegible]/100 per cent. It is therefore easy to understand that its aggregate passenger earnings were $3,509,702, as against $3,260,654 for the previous year, as stated in the same report—an increase of nearly a quarter of a million in this one item in a single year. The defendants admit that they are enabled to make these reductions because they use these labor saving inventions, and the figures quoted show that the reductions increase their profits enormously. They have therefore not surrendered the profits realized from the invention. They have simply converted them into a different form, and as they have had them they should account for them."

This reply is plausible, but unsound. We say nothing of the strange assumption that the increase in traffic on this road during the year mentioned was due to the reduction in rates, though it is plain that it might have been due to a hundred other causes. The real weakness in this line of argument lies much deeper. The patentee fails to distinguish between retail and wholesale. He insists on being paid the retailer's profit on the wholesale trade. He admits that defendants' profits on each individual transaction are less in consequence of this reduction in rates, but insists that his own profits on each indvidual transaction shall still be the same as ever. He fails to see that this is a rule that ought to work both ways. If he had been the patentee of the Mowry wheel he would have claimed his dollar a wheel, even though the defendant had been compelled to sell them at a profit of only fifty cents a wheel. If the patentee of the pin machine he would have claimed the full saving on every pin, though in order to make that profit the defendant had had to sell a thousand. If the patentee of the whole railroad, instead of this small part of it, he would have claimed his nineteen dollars a barrel, though in order to make that nineteen dollars the defendant had had to carry two hundred barrels. He would claim on each individual transaction the profit which defendant had been able to make only on a hundred or a thousand.

The absurdity of such a claim would be too plain to be denied, but unless there is some radical difference which we have failed to discover between those cases and that now before the court, the claim is equally absurd in this. The only reason why this absurdity is here less palpable is that the brake is not the whole railroad but only a part of it. But that certainly cannot affect the principle. For there is no more ground for assuming that the railroad puts into its own pocket the entire saving effected by one of the many devices used by it than there is for assuming that it puts into its pocket the entire saving effected by all these devices.

What then, it may be asked, is the actual profit to the road from the use of this brake and other similar devices; and how shall that profit be ascertained? There is one way, and as we believe, only one by which this can be done. That way is simple and definite; and perfectly easy of application. It is to take the *license fee* fixed by the patentee, and charge that to the defendant. The non-payment of that license fee is the only injury done to the plaintiff, and it is the only ascertainable profit made by the defendant. As this court says in *Mowry v. Whitney*, 14 Wall. 653, "The profits which are recoverable against an infringer of a patent are in fact a compensation for the injury the patentee has sustained from the invasion of his right. They are the measure of his damages. *Though called profits they are really damages.*"

So in *Seymour v. McCormick*, 16 How. 489, the court says, "The case of Stimpson's patent for a turn-out for a railroad may be cited as an example. It was the interest of the patentee that all railroads should use his invention, provided they paid him the price of his license. He could not make his profit by selling it as a complete and separate machine. An infringer of such a patent could not be liable to damages to the amount of the profits of his railroad, nor could the actual damages to the patentee be measured by any known ratio of the profits of the road. The only actual damage the patentee has suffered in such a case is the non-payment of the price he had put on his license, with interest and no more."

So in *Sanders v. Logan*, 2 Fish. 170, and again in *Livingston v. Jones*, Ib. 209, it was held by Grier J. that "if the inventor's profit consist neither in the exclusive use of the thing invented, or in the monopoly of making it for others to use, but in a general use by all who will pay the price of his license, the non-payment of the license fee is the only wrong done him. He has fixed his own measure of compensation."

It is true that in these three last cases it was a question of damages at law; but the same rule was laid down in *Amer. Nic. Pave. Co. v. City of Elizabeth*, 6 Off. Gaz. 766, which was a suit in equity; and finally, in *Burdell v. Denig*, 2 Otto, 270, this court has expressly declared that "in the absence of satisfactory evidence of either class in the forum to which it is most appropriate, the other may be resorted to, as one of the elements on which the damages or compensation may be ascertained."

There would be no difficulty here in fixing the license fee, for the patentee, as appears from his bill, has already licensed a large number of roads. Nor can it be pretended that the license fee so fixed would not be an adequate compensation, for it would yield at least half a million of dollars. We should thus be doing full justice to the plaintiff, and should at the same time escape the necessity of estimating his compensation on the theory of profits, the results of which, as we see in *Packet Co. v. Sickles*, 19 Wall. 618, have already awakened in the minds of this court a distrust that the prodigious finding in this case can hardly diminish.

Respectfully submitted,

GEORGE PAYSON,

Counsel for Defendant.

UNITED STATES SUPREME CO

CHICAGO AND NORTH-WESTERN RAILWAY CO

vs.

THOMAS SAYLES, *Appellee.*

ARGUMENT FOR APPELLANT.

BY B. C. COOK.

CHICAGO:
[illegible] & Co., Publishers, [illegible] Clark Street.
[illegible]

UNITED STATES SUPREME COURT.

CHICAGO & NORTH-WESTERN RAILWAY CO.,
Appellant,
vs.
THOMAS SAYLES.

ARGUMENT FOR APPELLANT,

BY B. C. COOK.

The main question in this case, whether the Tanner brake patent relied on by the plaintiff is a valid patent, and whether the use of the Stevens patent brake is an infringement of the Tanner brake patent, I do not intend myself to discuss; not because I have not full confidence in the contention of the defendant upon both these points, but because they are questions purely of patent law, and can be better discussed by counsel who have made that branch of the law a special study and are competent to discuss those questions in a much more satisfactory manner than I can hope to do. But there is one question in the case which rests on principles applicable to all suits in equity, to wit: the rule upon which the profits should be computed which are alleged to have been made by defendant by the use of the patent and to which the complainant claims to be entitled, which I wish briefly to discuss.

I suppose that there will be no dispute that the only inquiry to be made in ascertaining the amount which the complainant is entitled to recover in this case, assuming that he is entitled to recover at all, is what profits were actually made by defendant by the use of the Stevens brake on that portion of the road and for the time specified in the bill, and not profits which it might have made, but did not.

"The rule is based upon the idea that the infringer shall be converted into a trustee as to those profits for the owner of the patent which he infringes."

Burdell, et al., vs. Denig, et al., 92 *U. S. R.*, 720.
Cawood Patent (*Swedge Block Cases*,) 94 *U. S. R.*, 710.

I do not discuss the question whether a trust in a personal property can arise out of a simple tort without privity between the parties and without any intermeddling with a trust fund. It is sufficient for my present purpose to insist that the patentee's property is not converted into money until actual money or its commercial equivalent has come to defendant's hands, and it is only in respect of what has so come to its hands that the defendant can be sued in assumpsit or treated as a trustee *in inirtum.*

The defendant can be trustee only of some fund which it has actually made or saved by the use of the patented article; it cannot be a trustee of any fund which it has neither made or saved, although by different management it might have saved such fund.

Dean v. Mason, 20 *Howard*, 198.
Mowry vs. Whitney, 14 *Wall.*, 620.
Packet Company vs. Sickles, 19 *Wall:*, 611.
12 *American Law Review*, *No.* 2, *Jan.* 1878, *p.* 205.

There is no controversy at all between these parties as to what the actual facts are in relation to the use by defendant of the Stevens brake. The facts are stipulated as follows: (Record, pp. 849 and 850).

1611. UNITED STATES CIRCUIT COURT, NORTHERN DISTRICT OF ILLINOIS

THOS. SAYLES,
vs.
C. & N. W. R'Y. Co.
In Chancery.

It is hereby stipulated between the parties to the above entitled cause for the purpose of the hearing on complainant's claim for damages, that said defendants became a corporation and commenced running its cars and doing business on a portion of its railroad on the second day of June, 1859, and from that time until June 2d, 1864, used on all of its passenger trains in its said road double-acting car brakes, known as the Stevens Patent Brake; that such brakes were used on thirty-six eight wheeled cars running in its passenger trains, including all its passenger, baggage, and express cars. That it run four trains each day and six cars in each train on an average. That during said period said defendants run a mixed train daily, for freight and passengers, between Janesville and Chicago, being about ninety miles, on which there was usually one passenger car and one baggage, and that for one year during said period a similar train was run between Harvard and Rockford, the distance being about twenty-eight miles, and that the baggagemen on said two trains worked the brakes on said passenger and baggage cars. If extra passenger cars were run the conductors of said trains acted as brakesmen on the extra cars. The remainder of said thirty-six cars were in the shops for repairs or held in readiness for extra occasions. That each of said trains of six cars required and had two brakemen besides the baggagemen who acted as brakemen on all of said trains. That defendant paid its brakemen an average of thirty-four dollars and forty cents per month during said period of five years.

That during said period the actual cost of thirty-three inch wheels, such as were used under the said thirty-six cars, was sixteen dollars and seventy cents each wheel, and that the cost of taking off old wheels and putting new wheels on the axles, was one dollar each wheel.

That on the 2d day of June, 1864, said defendant consolidated its railroad and corporate franchises with the railroad and corporate franchises of the Galena & Chicago Union Railroad Company, and the new consolidated company retained the corporate name of the defendants.

(Signed) **WEST & BOND,**
Solicitors for Complainant.
H. W. BLODGETT,
Defendant's Attorney.

1613. U. S. CIRCUIT COURT, NORTHERN DISTRICT OF ILLINOIS.

THOMAS SAYLES,
vs.
THE C. & N. W. R'Y. Co.
} *In Chancery.*

It is hereby stipulated between the parties to this cause, by their respective counsel, as follows:

First. That the stipulation made herein between said parties, on the twentieth day of March, 1867, in reference to the number of brakemen employed by the above named defendants be amended, and it is now hereby stipulated that during all the time between the second day of June, 1859, and the second day of June, 1864, the said defendants employed on their railroad within said district, twelve regular brakemen for their passenger trains, beside the baggagemen on said passenger trains who also acted as brakemen.

Second. That during all of said time between the second day of June, 1859, and the second day of June, 1864, the said defendants used on their said railroad, at least two "way" or "caboose" cars in their various freight trains, each of which cars had upon it a "Stevens'" Double Acting Car-Brake.

Third. That during all said time, between the second day of June, 1859, and the second day of June, 1864, the said defendants removed the wheels of the thirty-six cars run in passenger trains on their said railroad, as per former stipulation, as often as once or twice a year, sometimes oftener, on account of flat spots, which rendered them unfit for passenger cars. Most of said wheels were then put under freight cars under the end of said freight cars that had no brake on.

Dated May 10th, 1873.

WEST & BOND, *Complainant's Solicitors.*
J. N. JEWETT, *Defendant's Solicitor.*

I have grouped all the evidence in the case which in my judgment has any bearing upon the question, whether the defendant did actually employ any less number of brakemen when it used the Stevens brake than it did when it used the single brake, and print the same as appendix "A" to this argument.

The finding of the Master upon which this decree was rendered, was as follows:

EXHIBIT "A" (Record, pp. 37 and 38.)

FIRST—*Brakemen Saved.*

For five years defendants ran constantly in passenger trains twenty-four cars, and required therefor twelve brakemen and four baggagemen, equaling in all sixteen brakemen.

The use of the patent is shown to have saved an equal number, that is, sixteen.

It is shown that on mixed trains defendants ran two cars, and required therefor one baggageman, equaling one brakeman.

The use of the patent saved here two brakemen.

On freight trains they ran two "caboose cars," requiring therefor two brakemen (or conductors).

The patent saved here two brakemen; making in all twenty brakemen saved.

The average wages of a brakeman for the time the patent was used, were thirty-four dollars and forty cents per month.

Wages of 20 brakemen would be $688 per month.

Wages of 20 brakemen would be $8,256 per year.

Wages of 20 brakemen for five years, $41,280.

I do not take into account the forward truck of the forward car of either of the defendant's passenger trains, which were four in number.

If the forward trucks were counted, the brakemen saved would be twenty-four instead of twenty.

Nor are the Harvard and Rockford mixed trains taken into account, which ran one year of the five, and on which two brakemen were saved by the patent.

SECOND— *Wheels Saved.*

For five years defendants ran constantly in passenger trains twenty-four cars.

On mixed trains they ran two cars.

On freight trains they ran two "caboose cars."

On Harvard and Rockford trains they ran for one year, two cars.

Equaling thirty cars per year for one year, and twenty-eight cars per year for four years; or,

Calling the wheels saved on the two caboose cars per year as equaling the wheels saved on one of the other cars per year, it may be stated as,

Twenty-nine cars for one year and twenty-seven cars for each of the other four years.

The patent saved two sets of wheels per car per year;

equaling fifty-eight sets saved for one year and two hundred and sixteen sets saved for the four years, or in all two hundred and seventy-four sets saved in five years.

Cost of a set of wheels was - -	$133.60
And of putting on a set - - -	8.00
Making cost of a set put on - -	141.60
Or for the whole 274 sets - -	$38,798.40
Value of old wheels, calling their average weight 500 lbs. -	$16,440.00
Deducting this amount, there is left for saving in wheels - - -	$22,358.40

In this estimate no account is made of any cars except those shown to have been constantly in use.

SUMMARY.

1st, Saving in brakemen - -	$41,280.00
2d, Saving in wheels - -	22,358.40
Total amount due complainant	$63,638.40

(Sixty-three thousand six hundred and thirty-eight dollars and forty cents.)

The Master reports that on the 4 passenger trains, defendant saved four brakemen on each train, or 16 in all. If this is so, then when those trains were run with a single brake they had 32 brakemen on the 4 trains, or 8 brakemen on each train of 6 cars. The baggage car was always one of the 6 cars in the train; on this car the baggageman operated the brake, leaving 7 brakemen for the other 5 cars. Now the truth is that not only is it not shown that the defendant ever had any more brakemen when it used the single brake than it had when it used the double brake, but it is affirmatively shown by persons who knew the facts, that it had not. Benjamin Garvin, the only witness who testifies directly upon this point, p 962, says that he was connected with the Chicago & Northwestern road, and it was not the custom of that road to use more brakemen with the single than with the double-acting brake. So far from there being any proof in the case that there was ever 7 brakemen used on the 5 passenger cars of defendants train, or that 8 brakemen were used on a train of 6 cars no witness on either side testifies that more than one brakeman to a car was ever used on any train on any road when single brakes were used. I submit to the Court that by no construction of the testimony in this case can it possibly be made to appear that defendant did in fact save 16 brakemen on its four passenger trains; on the contrary it is affirmatively shown that the number of brakemen was not diminished by the substitution of the double for the single brake.

The Master says: "It is shown that on mixed trains, defendants ran two cars and required therefor one baggageman, equaling one brakeman."

"The patent saved here two brakemen."

The meaning of this sentence I suppose to be, that it is shown by the stipulation, that after the double brake was adopted, defendant had but one brakeman, who, also, was baggageman, upon the baggage car and passenger car, and thereby saved two brakemen.

Now there is no testimony in the case tending to show that the defendant ever did, in fact, have two brakemen on that passenger car in addition to the baggageman who used the brake on his own car.

The Master says: "On freight trains they ran two caboose cars, requiring therefor two brakemen or conductors.

"The patent here saved two brakemen."

This is on the assumption that when the single brake was used the defendant had four brakemen upon these two caboose cars. There is no such testimony in the case; on the contrary it is shown that it did not.

It is shown by the proof that when the single brakes were used the baggagemen worked the brake on the baggage car, and the conductor of freight train acted as brakeman on caboose car when necessary, and after the double brake was put on they did not so act; and this is all the change proven. Not one man less was carried on the train to operate it.

The Master reports that half the baggagemen were saved. If this is so then no baggagemen at all are needed on a train using the Westinghouse brake.

Is it not evident that on every train a baggageman must be carried, and that, wholly independent of the question whether he does or does not operate a brake on the baggage car? (See testimony of H. B. Milliken, p. 916.)

According to the rule adopted by the Master, there was on the baggage car when the single brake was used, a baggageman and a brakeman; all the proof contradicts this assumption. As the Master finds that defendant saved

$200.64 by each of these (imaginary) brakemen saved by use of the patent, the defendant is charged with $41,280 on this account alone.

It is difficult for me to discover, from the testimony, what led the Master to the conclusion that these brakemen were actually saved by the use of the patent; but I suppose that it was the evidence that in the opinion of some of the witnesses it would take only half the number of men *to apply the double brake to a train* that would be required to apply the single brake with the same power and effect. There is certainly no other evidence in the case upon which the conclusion of the Master can be based, and he doubtless assumed that if it took only half as many men to work double brakes on a train as it did single brakes, that half the brakemen were saved.

This conclusion involves three fundamental errors:

1st. That the amount of whatever reductions could be made in the cost of running the trains was saved by the company.

2d. That the rate of speed and weight of cars in the times when single brakes were used, was substantially the same as during the time when double brakes were used and as much power was necessary to operate the brakes.

3d. That the service of brakemen was exclusively to work the brakes, and so when the brakes could be worked by fewer men, the train men whose services were no longer required to work the brakes could be dispensed with altogether.

Neither of these propositions are true in fact or established by the evidence, and no one practically acquainted with the running of trains would have assumed them to be true.

First. A portion of this road is in Illinois and a portion in Wisconsin ; in the latter State, the railroad company has not the power, by law, to fix the compensation which it shall receive for the use of its property and the services of its agents. This court has decided that this power is vested in the State, and the natural result is that the charge to the public for the transportation of freight and passengers must be regulated by the actual cost of such transportation at the time.

The affidavit of President Keep upon page 48 of the record, states the fact, "That no railroad company ever has, "or ever can, put into its own pocket the amount saved by "any improvement, patented or not, but is obliged, in fact "driven and compelled, constantly to reduce its rates, and "thus to share with the public the benefits and advantages "of every such invention and improvement."

It may be said that this affidavit is not evidence in this case upon this question. The answer is that it is a fair method of stating the argument, and the burden of proof to show the gain is upon complainant, and he has no right to assume that in the case of a corporation, "engaged in a public employment affecting the public interest," that all reductions in the cost of doing its business is a gain to the corporation itself. If the public have the right to fix the limit of the compensation it can receive, and then all patentees have the right to hold it liable as trustee for all reduction in the cost of transportation, regardless of the question whether the benefit of such reduction enured to the public or the company, it is placed between the upper and nether millstone.

The operation of the rule adopted by the Master may be shown by a simple illustration. A railroad company receives the sum of $25 for transporting a car load of freight from Chicago to New York, over its railroad. Had there been no railroad, and had the company contracted to carry the freight by wagons, or in some other manner, it would have received $100 therefor; has the company saved $75? Could it under any circumstances become a trustee for any person, of the $75 difference between the sum it actually received and the sum it would have received under other circumstances?

Second. The evidence conclusively shows that trains were not run at the same rate of speed, or the same weight of cars, when the single brakes were used, and consequently the amount of power required to work the brakes was not so great. The increase of speed is the aggregate result of many improvements. Perhaps the most important of these improvements is the substitution of steel for iron rails, the use of patent chairs, improvement in locomotives, in annealed car wheels, the Westinghouse brake and the Miller platform. The proof shows that the speed was not as great when single brakes were used, and does not show that the adoption of the double brake has been more than one of the least effective of many causes that have combined to make the increase of speed possible. I quote the testimony of a single witness on this point; there is no testimony in the case which conflicts with it.

Samuel J. Hayes, p. 960. "I would not consider it safe "now, with our present knowledge of railroad machinery, "to run passenger trains as they are now run, with the "same number of brakemen that were engaged on passen-"ger trains twenty years ago. The speed is greater now "than it was then; with an increased rate of speed an in-"creased number of brakemen is required.

THIRD. But the greatest error, in this mode of computing damages, is the assumption that the duties of a brakeman are only to man the brakes, and consequently that when a less number of men are required to work the brakes the number of men necessary for the running of a train is reduced by the same number; this is a fallacy. The error arises from calling these employes brakemen instead of train men, and assuming that their sole duty was to operate the brakes. It is necessary in the running of every train to have a sufficient number of men to guard the train at the place of starting, to prevent improper persons from entering the cars, to protect the property of the passengers, to render assistance to all persons requiring assistance in entering and leaving the cars; at every station there must be men enough to assist aged and infirm persons to alight. There must be men enough to see that persons do not enter the cars without tickets. There must be men enough, in case of any accident or detention, to send each way upon the track to signal advancing trains.

The law requires the use of the most efficient means to protect the person and property of passengers and holds railroad companies to a severe accountability for any failure in this regard.

N. O. St. L. & C. R. Co. vs. Burke, Sup't Ch. Miss., Oct. T. 1876, *Cent. Law Journal, June* 8, 1878.

Norwich Transportation Co. vs. Flint, 13 *Wall.*, 3.

Maverick vs. 8th Avenue R. R. Co., 20 *B. & C.*, 282.

Pittsburgh, F. W. & C. R. Co. vs. Hinds, 53 *Penn. St.*, 512.

The duties of the train men are also to assist in making up trains, keeping fires, lighting the cars, and during the time specified in the bill, one of their duties was to assist in wooding the engine. It certainly cannot be fairly assumed, without proof, that because fewer men were required on a train to operate brakes, that therefore that number of train men could be dispensed with. Upon the principle adopted by the Master in making this computation, no brakemen would be required now upon a train which has the Westinghouse brakes, for all the brakes are applied by the engineer, and yet the practical fact is that the same number of train men are required upon trains, that was required before the Westinghouse brake was used.

Samuel J. Hayes, who has been a practical railroad man since 1840, testifies, p. 960: "There was not any more "brakemen used with the old-fashioned brake, than with "the double brake on roads that I have been connected "with, nor had I noticed that there was in my observation "in passing over other roads. It has always been the custom to have two brakemen on an ordinary passenger train, "and it is still the custom."

To the same effect is the testimony of *Peter M. DeCamp*,

p. 920. *Louis Elder*, p. 921. *Benjamin Garvin*, p. 962. *John B. Adams*, p. 1,020. *Henry Waterman*, p. 1,126, testifies: "The only advantage of the air brakes over the "hand brakes is that the air brakes are in the first place "under the control of a single mind, and that they apply "the brakes to all the wheels of a train as nearly simul- "taneously as possible. I know of no other advantage, "*true the brakes work without a brakeman but yet the same* "*number of men would be required as the gang of a train.* "*I don't think it lessens the number.*"

The principle upon which the Master arrived at his conclusions applied universally would lead to strange results.

Among the improvements that have been patented in running a train are the following:

WAY.	Prior to 1874.	Since 1874.	Total.
Railroad ties, crossings, guards, cleaning track, turn tables, gates, etc.	741	120	861
Add wire fence patents		116	116
Rails, rail joints, chairs and nut locks, not including devices for mending rails such as Cawood's block	708	327	1035
Signals	86	102	188
Switches and Frogs	373	151	524
ROLLING STOCK.			
Cars and furniture *exclusive* of following items	492	439	931
Brakes and *attachments*	535	205	740
Wheels and trucks	503	125	628
Couplers and buffers	977	651	1628
Springs—special car and locomotive	199	38	237
Locomotive, boiler, blow offs, flues, gauge, condemn, feed water heaters &c., not including the following items, and excluding about 13000 on "steam engine" and patents of other titles, the exact number of which could not be ascertained without examining each patent	1276	475	1755
Fire box, grate and door	200	113	313
Smoke stack, exhaust, and spark arrester	239	73	312
Pistons, valves, and stuffing boxes	1433	364	1797
Lubrication, journals and axle boxes	865	347	1212
Tickets	69		69
	8696	3646	12342

Of which patents over ten thousand are now alive and operative.

Some of which are of the first importance in operating every road, such as the steel rail, the patent chair, the

Westinghouse brake, the annealed wheel, the Miller platform. The various improvements in locomotives.

If we are to assume that a railroad company has saved on its business all the sums by which the cost of operating a road has been reduced by these improvements severally upon the principle adopted by the Master in this case, we reach the extraordinary conclusion that the companies have severally, actually saved much more than their gross receipts; certainly much more than their net earnings, because the cost of transportation is not half as great as it was before any of the improvements were made.

But the rule adopted by the Master in arriving at the amount saved in car wheels is still more liable to objection. The stipulated facts are, that between June 2, 1859 and June 2, 1864, the defendants removed the wheels in thirty six cars run in passenger trains as often as once or twice a year, sometimes oftener, on account of flat spots which rendered them unfit for passenger cars. under the end of freight cars that had no brakes on. This was during the time that the double brakes were used. It is assumed that the patent saved two sets of wheels per car, per year, which would make four sets of wheels per year spoiled by the use of the single brake. Now, there is no testimony in the case showing or tending to show that defendants used four sets of wheels upon its passenger cars in a year at the time single brakes were used. There is testimony tending to show that on some roads using the single brake, from two to three sets of wheels were used. But the most singular fact is that the Master while determining that two sets of wheels per year were saved, gives credit for the value of the wheels as old iron only, while the stipulation which is all the proof upon this point in the case, shows that the wheels were put under the end of freight cars that had no brakes on. The Master has assumed that these wheels which were fit for and were used as freight car wheels, had no more value to the defendant than old iron; an assumption which seems to us unreasonable and absurd, but which is absolutely necesssary to support the finding in this case. It certainly appears from the stipulation that most of these wheels were suitable to be used as freight car wheels, and the fact is, that when a wheel began to be a little worn by the use of the brake they were taken off and put under the end of a freight car that had no brake, for the purpose of saving the wheel, and not because the wheel was worthless; when the wheel first began to be a little flattened at any point the wearing of the wheel would go on at that point much faster than before, but if the wheel was taken out and placed under the end of a car where there was no brake, it would do about the same service as a perfect wheel. Upon what principle could the Master say that a wheel which can be and is used on a freight car has no more value than old iron?

It is this loose and erroneous manner of computing profits that were never made—or saved, that swells this finding to proportions ruinous to defendant; the profits are assessed upon a small part of defendant's road only, and up to 1864. Another suit claiming $800,000 profits has been commenced against this company by this complainant, which is now pending. The person who purchased this patent has valid claims against the railroads of the country to the aggregate of $60,000,000 upon the same rule of ascertaining profits. (See affidavit of President Keep.) The complainant's own valuation of the patent is shown by his settlement with the Hudson River R. R. Co., giving that company the right to use the patent for $1,000. His verdict in an action at law against N. Y. Cent. R. R., was $1,500, (Rec., p. 606) and against the N. Y. & Erie, $75. (Rec., p. 637.)

In this connection, I desire to call the attention of the Court to the ruling of this Court in the case of *Packet Co. vs. Sickles*, 19 Wall., 617, it is there said that "The rule "in suits in equity of ascertaining by a reference to a Master the profits which the defendant has made by use of "the plaintiff's invention stands on a different principle. "It is that of converting the infringer into a trustee for the "patentee as regards the profits thus made, and the adjustment of these profits is subject to all the equitable considerations which are necessary to do complete justice "between the parties, many of which would be inappropriate in a trial by jury, with these corrected powers "in the hands of the Chancellor, the rule of assuming "profits as the ground work for estimating the compensation due from the infringer to the patentee, has produced "results calculated to suggest distrust of its universal application even in courts of equity." Certainly the rule should not be extended and enlarged to the extent that it must be if the Masters rule for computing damages in this case be sustained.

I submit that the rule for ascertaining profits in this case was erroneous, impracticable and oppressive. That no such profits as the Master has found were ever made or saved by the defendant.

Seymour vs. McCormick, 16 *How.* 272.

Corp. N. Y., vs. Ransom, 23 *How*. 490.

I ask leave to refer the Court to a full discussion of this question in the American Law Review for October, 1878, p. 1, title, "Money recoveries in patent suits."

This is not a case where defendant should be punished for any willful violation of complainant's rights.

The Stevens patent, the right to use which was purchased by defendant, was issued long before the Tanner patent was issued, and was being used while the application of Batchelder & Thompson was remaining in the patent office, and while the Commissioner of Patents was writing to them as follows:

PATENT OFFICE, Oct. 17, 1871.

GENTLEMEN:

Specifications and drawings of your alleged improvements in railroad car brakes are herewith returned for entire insufficiency. The office from what it can learn of the case cannot encourage you however to prosecute the application further. (See Record, p. 121).

Compelled to adopt the best improvements, yet left to decide almost in the dark, the managers of this company cannot be charged with willful disregard of complainant's rights because they failed to discover in the insufficient model, specifications and drawings of Batchelder & Thompson, the principle for which Stevens had obtained his patent.

B. C. COOK,

Gen'l Sol. of C. & N. W. R'y Co.

APPENDIX "A."

Testimony in relation to the question whether the defendant run its trains with any less number of brakemen after it began to use the Stevens patent brake, than it employed on the same trains before it used that brake.

Printed Record page 906. *Cyrus W. Burton.*

1*st Cross-question.* How many brakemen were employed on the passenger trains on the New Haven road run by you, as a general rule, when single brakes were used?

A. As a general rule, one to three cars.

2*nd Cross-q.* What number, as a general rule, were employed when they used the double brake?

A. The same number.

Page 907. 15*th Cross-q.* Do you mean to say that you have not run by a station for receiving and discharging passengers but once in six months?

A. I do; so as to be obliged to back up.

16*th Cross-q.* How many cars in such trains, and how many brakemen in the three months spoken of?

A. Six or seven cars, and two brakemen.

17*th Cross-q.* Would not, in your judgment, the result have been the same if you had had the single brake on the same cars, and four brakemen working and operating the brakes simultaneously?

A. Well, my judgment is, if you guarantee the four men to work simultaneously, I've no objection, but should prefer the other two; it might make a little difference.

Page 909. *James E. Hutton.*

Question 2. About how many years have you been running as locomotive engineer?

A. Well, about thirty years.

Question 3. Upon what railroads?

A. The New Jersey Railroad, the Erie Railroad, the Staten Island, the Harlem, the Charleston and North-eastern, the Charlotte and South Carolina, and the Texas and New Orleans.

Page 910. *Cross-q.* 1. How many brakemen were employed on the trains run by you when the single brake was used?

A. Sometimes one, sometimes two; according to the number of cars we had.

Cross-q. 2. How many brakemen, on an average?

A. I never knew more than two on one train when we run with a single brake.

Cross-q. 3. How many on an average were employed when the double brake was adopted?

A. They had about two to a train ; sometimes they had more.

19 A. I never run on any road where the single brake was used except the New Jersey and the Harlem road. On the Harlem road they used to run one to two cars in a train, and they had but one brakeman. On the New Jersey road they used to have about one brakeman to three cars. The New York train had three cars and two brakemen. The Philadelphia train had five or six cars and two brakemen.

Page 914. *John P. Ray. Cross-q.* 25. How many brakemen did they employ on a train when they used a single brake?

A. There is a difference in roads ; the average would be about one man to two cars.

Cross-q. 26. What was the average when the double brake was used?

A. They would use about one-third less brakemen.

Cross-q. 27. In the running of three to five cars, do they use more than two brakemen in either case?

A. I have known them to use three brakemen, the baggage-master being counted, and the conductor, too, sometimes ; that would make four brakemen with the single brake, two brakemen on the pay-roll ; with the single brake, the baggage-master and conductor would brake, whereas with the double brake they would not.

Page 916. *H. B. Milliken. Cross q.* 1. How many cars, as a general rule, made up a train on the Fitchburg road?

A. About five cars.

Cross-q. 2. How many brakemen were employed on those trains?

A. Two brakemen and a baggageman. In those times the baggageman almost always broke, and the conductor broke in those times; we also used to brake on the tenders. We don't ever brake on the tender now to stop at stations.

3 *Ans.* They had a single brake on each end.

4 *Cross-q.* Could not two brakemen, a baggageman and conductor control a train of four or five cars with a single brake, a fireman using a brake on the tender, do as good execution in stopping the train at stations, as two brakemen would with the double brake on the same number of cars?

A. No, I don't think they could.

5 *Cross-q.* Please give your reason for this answer.

A. The conductor or any one of them might put the brake on hard enough to slip the wheels, while another one might not put it on hard enough to do the necessary execution; while one man governing the whole eight wheels, one man is considered to apply to all the wheels of two cars, and the friction comes more regular on the wheels with the double-acting brake.

Page 920. *Peter M. DeCamp.* Locomotive engineer for a little over 25 years.

2 *Cross-q.* The number of brakemen employed when I was engineer, when they used single brakes, was a good deal owing to the number of cars. If we had two or three cars, we would have one brakeman beside the baggage master; when we had four or five cars, we would have two brakemen besides the baggage master.

Page 931. *Lewis Elder.* *Cross-q.* 3. The trains I ran numbered from six to nine cars. Three brakemen were employed on such trains, to the best of my recollection, when the double brake was used, and I think the same number and the baggage master in addition when the single brake was used.

Page 930. *Joshua P. Martin.* Worked as fireman and engineer since 1834 on several different roads. *Cross-q.* 3. On the Erie road when the single brake was in use the average number of cars in a train was five. We had a man to apply the brakes to each car; they were all applied by brakemen, baggageman, or conductor.

Page 958. *Nathan W. Huntley.* *Cross-q.* 1. It would require two brakemen to apply the brakes on all the wheels of two cars in a train with the so-called Tanner brake, as is now practiced by railroad companies. It would require three to apply the brakes to all the wheels of two cars in a train with a single brake, as usually practiced.

Page 959. *Thomas Hull*, *Q.* 4. I should put one brake man to every car on a train of passengers with the Stevens brake, to secure the highest degree of safety. It would require three brakemen to apply all the brakes to six cars with the Stevens or Tanner brake, and to apply all the brakes to such a train with the old single brake would require seven.

Page 960. *Samuel J. Hayes.* *Q.* 11. Served since 1840 on Baltimore & Ohio and Illinois Central Railroads. There was not any more brakemen used with the old-fashioned brake than with the double brake on roads I have been connected with, nor had I noticed that there was in my observation in passing over other roads. *It has always been the custom to have two brakemen on an ordinary passenger train, and it is still the custom.*

Cross-q. 4. It would take five brakemen to apply the brakes to all the wheels of such a train as quick as two would apply it with the double brake, but the same number of brakemen would apply all the brakes by passing through the cars; we used to consider it safe to depend on the brakemen passing through the cars, first applying the brake on one end of the car, and then on the other, that was the custom.

Cross-q. 15. According to the usual practice of applying the double acting brake to passenger trains, it would take double the number of brakemen to apply all the brakes at the same time with an odd number of cars; with an even number, it would take one more than double the number. I would not consider it safe now with our present knowledge of railroad machinery, to run passenger trains as they are now run with the same number of brakemen that were engaged on passenger trains, twenty years ago. The speed is greater now than it was then; with an increased rate of speed, an increased number of brakemen are required.

Page 962, *Benjamin Garvin;* connected with railroads

24 years, the Concord and Nashua, Northern New Hampshire, Vermont Central, and Chicago and North-Western. It was not the custom on those roads to use more brakemen with the single than with the double acting brake.

George L. Dunlap; was Superintendent of the Chicago and North Western Railway Company, from June, 1859 to June, 1864. The general practice was, they used more brakemen when the single brake was used than now.

Page 982. *F. D. Adams*, Car Builder, *Int.* 136. One additional brakeman with single brakes would handle a train as well as three brakemen would handle the train with the double brake.

Page 1020. *John B. Adams;* Railroad Conductor for thirty years. *Int.* 28. I can stop my train with three brakemen and single brakes on a dry rail as quick as I can with a double brake and three brakemen. If I had to change double brakes for single brakes on my train, I think an increase of one man to the number of brakemen on a train would be all that would be required.

Our trains in 1843, comprised only two cars, and occasionally three, with the crate car, and always carried two brakemen and baggageman, who broke on his own car as the number of cars on our train increased. We did not increase the number of brakemen while we used the single brake.

Page 1126. *Henry Waterman;* Mechanical Engineer, *Cross Int.* 72. The only advantage of the air brakes over the hand brakes, is that the air brakes are in the first place

under the control of a single mind, and that they apply the brakes to all the wheels of a train as nearly simultaneously as possible. I know of no other advantage; true, the brakes work without a brakeman, but yet the same number of men would be required as the gang of a train. I don't think it lessens the number.

SUPREME COURT,

OF THE UNITED STATES.

CHICAGO & NORTH-WESTERN RAILWAY CO.,
Appellant.

vs.

THOMAS SAYLES, *Appellee.*

ARGUMENT FOR APPELLANT,

BY B. C. COOK.

Filed the..day of

....A. D., 187

....

Clerk.

Printed by H. Willson & Co., 170 Clark Street, Chicago.

United States Supreme Court.

The Chicago & Northwestern Railway Company
vs.
Thomas Sayles.
No. 48.

ARGUMENT FOR APPELLANT

BY

THE LATE B. R. CURTIS.

In the Circuit Court

May it please the court:

It has been already stated to your Honor that it is not my intention to discuss any of the controverted questions of fact involved in this case, and that I shall confine what remarks I have to make mainly to the subject of infringement. I desire, however, to submit to the court a few observations concerning the legal aspects of what was transacted in New Jersey in 1842 by Stanley and Tolson, without going into any disputed questions of fact, but upon the assumption that the facts are as they are assumed to be, or asserted to be, on the other side.

The time of these transactions is not in question. It was in 1842, and unquestionably prior in time to anything effectually done by Batchelder and Thompson; and the only question is, whether what was then done, so far as it is satisfactorily proved in this case, and is by the other side admitted to have been done, amounted, in contemplation of law, to an invention, so as to anticipate the invention of Batchelder and Thompson.

Now that which was done, which is clearly proved, and, as I understand, not controverted on the other side, is this: That Stanley conceived the idea of such a break as is now in question; that he made a model sufficient to exhibit the plan of such a brake, but, owing to its defective construction, not capable of being put into actual use and kept in actual use upon a car; that in the attempt to use it it was broken, taken off, and laid aside; that Tolson, who was an experienced constructor and the head of the mechanical department, under whose administration this experiment came, so far as the railroad was concerned in its trial, proceeded at once to put into iron the necessary parts of the plan indicated by Stanley; that he did so; that he duly proportioned those parts for size and strength; that he applied the thing thus made to a car; and several, precisely how many, trips were made by the car with this brake in use, does not appear. We offer evidence to confirm Tolson's statement that it was in use continuously for a considerable period of time; whereas it is insisted, on the other side, that the statement formerly made by him as a witness at Albany is the correct statement, and that this car having this brake upon it made but a few trips on the road—two or three—perhaps a little more, perhaps a little less.

Now, these are the uncontroverted facts in reference to what was done by these two persons at this time; and the question is, whether that does or does not amount, in contemplation of the patent law, to a completed invention, so as to anticipate the invention of Batchelder and Thompson, subsequently made.

There is, as I dare say your Honor has observed, a good deal of looseness among patent lawyers in the employment of the word "abandonment." They do not distinguish between abandonment of the pursuit of an invention and abandonment of an invention after it has been attained. If a person has conceived in his own mind the plan of an invention, and is proceeding by means of drawings or models, or actually working parts to endeavor to reduce it to practice, and before he has arrived at the point of its actual reduction to practice he abandons his attempt, he has, in contemplation of the patent law, done nothing. That is abandonment of the pursuit of an invention; and it anticipates no one who afterwards enters the same field and pursues the same plan up to the point of its reduction to actual practice.

On the other hand, if the pursuit has been so far prosecuted, either by one or more minds and hands, that the actual reduction of the plan to practice has been made, and the thing has been put into use, the invention is then complete; if then abandoned it is abandoned to the public; and it is abandoned to the public finally and as respects all persons who come afterwards, because, as the original inventor has the inchoate right to obtain a patent, when he abandons that inchoate right he abandons every right; and every subsequent inventor, although he may be an actual inventor, has no inchoate right to a patent, and if he obtains one it is void.

I have said, may it please your Honor, that if the invention is attained, if its pursuit is followed up to the point of attaining the invention, in contemplation of the patent law, by reducing the intellectual conception to actual practice, then the invention is made; and if an abandonment takes place, it is to the public. Was not that the case in this instance? Importance seems to be attached by the other side to the fact, which they assert—which we do not admit, we controvert it, but for the purpose of this argument I assume it to be true—that this car with this completed brake on it passed over the road but a few times. I attach no importance to this. If this plan was reduced to iron, the parts having the proper sizes and being properly put together, so that it could operate as a brake, and it was actually applied to a car and put in use, it is a complete invention and anticipates whatever comes afterwards; and if it is then abandoned, either because those who possess it do not understand its value, or because the circumstances in which they were placed did not render it valuable at that time to them or their employers, it is abandoned to the public, and no subsequent inventor can claim any right. Must not this be so, may it please your honor? If the learned counsel on the other side are not satisfied that a car making one trip with such a brake in actual use—that that amounts to a complete invention—how many trips must be made—what amount of use is necessary? Manifestly, the patent law has drawn no line, and contains no principle which gives any indication of the *amount* of practical use into which the subject-matter must be carried. What it demands for a complete invention is that there should be something more than the intellectual conception; that in addition to the intellectual conception of the plan there shall be a reduction of that conception to practice; that is all it demands; that is all it is possible for the law to demand in the way of practice, unless the legislature shall step in and make some arbitrary enactment as to the amount of use.

I submit, therefore, that on the uncontroverted facts as they were admitted by Mr. Cozzens here at the bar to be, when he said that Tolson told the truth at Albany, it appears that he there described a complete invention, reduced to practice, and put into use; and in confirmation of these views I beg leave to refer your Honor, instead of citing a case, to sections 87 and 91 in the last edition of Curtis on Patents, where the cases on this subject will be found to be collected, and the principles of law which I have been relying on are laid down and supported by the authorities. There is one very striking case there cited, which I wish to occupy a moment's time in stating to the court. It was a trial under a patent for a water-wheel, before Justice Nelson. A witness appeared who stated that at a certain time a person, whom he didn't know, who lived at a distance, applied to him, he being a millwright, to make a small water-wheel for him; that he described to him a plan of the water-wheel; that the millwright made it according to that plan; and the plan contained the same novelties on which the patent was founded; that the person who employed him appeared in due time and paid him for the water-wheel and took it away. He didn't prove any use of it; he didn't know that it was ever put into any use; and yet Mr. Justice Nelson told the jury that if they believed that statement, that was a complete invention, although it had only been put into a condition when it might be used—when it could be used—in the proper way and proper place; but it didn't appear that it had ever been thus attached or used at all.

I leave this part of the argument, may it please your Honor, and come to that which will require more comment—the subject of infringement.

I wish the Court, in the first place, to inquire what is *the class of* *inventions* to which it is claimed this patent belongs. Batchelder and Thompson do not claim that they were the inventors of railroad brakes; they disclaim that in so many words in their original specification. In the original specification they say, in so many words, they do not claim to have been the inventors of railroad brakes; and it is manifest they were not. Neither were they the first inventors of a mode of connecting the brakes between the two trucks. They point out in these specifications that they were not, and do not claim to have been the first inventors of a *mode* of connecting the brakes in railroad trucks. The mode which they here expressly disclaim is one where the momentum of the cars, or rather they have alluded to two different modes where the momentum of the cars, was employed, instead of the hand of the brakeman, to operate the brakes. But, nevertheless, the brakes in the two trucks were connected together by machinery, and they were so connected together, and so adapted to use, that instead of employing the hand of the brakeman the momentum of the car was employed. But the evidence in the case, may it please your Honor, carried the art of connecting the two brakes in the different trucks of a car much further than this.

In the first place, it appears by the testimony of Mr. Wilson Eddy, in the proofs used at the previous hearing of this case that a tender was made at Springfield, and put into use, having the brake lever of the forward truck connected with the brake lever of the hind truck; and the brake lever of the forward truck connected with a windlass, so that a person at the forward end of the tender could, by working the windlass by means of the connecting rod between the two brake levers, operate both at the same time.

I will read, if your Honor please, a short passage:

"In December, 1840, we had a severe accident here in Springfield, owing to the deficiency of the brakes of the engine and train. Coming down this grade (that is the grade in this city, there is a steep grade east of the city), an engine and train were badly smashed up, and four men lost their lives. When this engine and tender were repaired, and before it was put upon the road again, there were brakes put on both trucks of the tender; they are operated from one windlass, by a connecting rod, running from the top of the lever on the forward truck to the top of the lever on the rear truck. The lever on the first truck was operated by a windlass the same as a single brake, and the same as if a rear truck hadn't been connected with it. This tender went out of the shop in 1841, I think in May. Mr. Harris got up this brake, made it, and applied it to the tender. This brake has been used from that time constantly, on the tenders on this road, and is the one now in general use on our tenders."

Now, Mr. Whipple, I would be glad to have you exhibit to the Court a car to which a similar arrangement was applied there. Please to show that to the Court.

(Mr. Whipple produces a model.)

Your Honor will find, by looking at it, that instead of having one connection by a connecting rod, passing from the top of one brake lever to the top of the other brake lever, it has two connections. It differs from the description I have here simply in that fact. Now I will read the residue:

"The brake shown in the model now before the commissioner, marked 'model A' [that is the one before your Honor], was got up and applied to two crate cars by Mr. Harris, in 1842 or 1843, and, according to the best of my recollection, it was in use on those cars, as long as the cars were in use, which was some two or three years. I can't recollect the time exactly. When the cars went out of use, the necessity for that kind of double brakes went out with it."

Your Honor, of course, will understand that I am not about to argue that this anticipated the invention of Batchelder & Thompson. I am only endeavoring to show the Court *the field* as it existed when they entered it, when they made their invention; and we find, as I have already stated, it is proved by this evidence, that not only were they not the first to connect together in any manner the brake levers of the two trucks, but that they had been connected together at Springfield, by a connecting rod passing from the top of one brake lever to the top of the other brake lever, and also by two connections, as shown in the model which is now exhibited to the Court.

Further than this, may it please your honor, it appeared—and here it will not be necessary for me to read from this book, because your Honor doubtless will recollect accurately the evidence on the subject—it appeared that one Millholland had invented a still different mode of connecting the two systems of brakes prior to the invention of Batchelder and Thompson. He employed, instead of a center lever to make the connections, a drum with cords or chains—a pulley or drum, with cords or chains passing over it. Still I agree that this was different from Batchelder and Thompson; and perhaps did not anticipate the invention of Batchelder and Thompson; but at the same time *it approached exceeding near to their invention;* and with these three things before the Court, it is apparent that it was not for Batchelder and Thompson to claim, and that consistent with the truth of things they could not claim, that they were the first persons, *in any manner*, to connect the brake levers in the two trucks for the purpose of operating them from either end at pleasure, because it had been done before.

Well, what did remain to them—what was the field into which they could enter? Why, it was to devise some *novel*, *particular*, and *better* way of doing this same thing. That did remain to them. For the purpose of this argument I concede that they did so; that they entered this field and did devise *a particular mode of making this connection*, which differed substantially from any special mode that had been practised before; and that *for that particular mode which they* *thus invented* they could take their patent, but not for *the result* which was obtained, to wit, the connection of the two brake levers in the two trucks, so that they could be operated at either end; not *for any means whatever* of connecting the two, but strictly and exactly for *the particular means* which they devised, and for any other means which were *substantially the same.* And here I beg leave to read to your Honor, because the rule is there stated better than I can state it, a pssage from the opinion of Chief-Justice Taney in the case of O'Reilley and Morse in the 15 Howard: "But the discoverer that a certain useful result will be produced in any art, machine, manufacture, or composition of matter, by the use of certain means, is entitled to a patent for it, provided he specifies the means he uses in a manner so full and exact that any one skilled in the science to which it pertains, can, by using the means he specifies, produce the result he describes. If this cannot be done by the means he describes, the patent is void; if it can be done, then the patent confers on him the exclusive right to use the means he specifies to produce the result or effect he describes, and nothing more; and it makes no difference in this respect, whether the effect is produced by chemical agency or combination, or upon application of principles in natural philosophy, or by machinery acting upon mechanical principles. In either case, he must describe the manner and process as above mentioned, and the end that it accomplishes; and any one may lawfully accomplish the same end, without infringing the patent, if he uses means substantially different from those which are described."

Now, in reference to the state of the art which existed at the time of the invention made by Batchelder and Thompson, in reference to the field which they *could* occupy, in reference to what remained to be done in that field, I desire to read a passage from the case of McCormick *vs.* Talcott, in the 20th Howard, page 404:

"If he (that is the patentee) be the original inventor of the machine, called the divider, he will have a right to treat as infringers all who make dividers operating on the same principle and performing the same functions by analagous means or equivalent combinations, even though the infringing machine may be an improvement of the original and patentable as such. But if the invention be in itself but an inprovement on a known machine by a change of form or combination of parts, the patentee cannot treat another as an infringer who has improved the original machine by the use of a different form or combination, although performing the same functions. The inventor of the first improvement cannot invoke the doctrine of equivalents to suppress all other improvements, unless they are mere colorable invasions of the first."

Now these cases are decisions of the highest authority; they are the law of this Court, of course; I desire to ask your Honor to apply these principles to the facts of this case; and in order to do so it will be necessary for me, somewhat tediously I fear, to go through with a statement of what are the various parts of these two arrangements; what are the functions of each of those parts, and what are the effects or results which they produce; and to trace those diversities of effect to those diversities of construction and of function in the two machines. Your Honor is quite familiar with both structures, and therefore I apprehend that it will not be necessary to look upon the models. If your Honor desires to do so, they shall be placed before you.

What Batchelder and Thompson did was this: they took the existing truck, which had a brake lever, the short arm of which was attached to one of the brake bars, and the other brake bar, through its connection with the lever, was made the fulcrum of that lever. The top of this lever was connected with a windlass; of course the lever stood on the outside of the truck, near the windlass, its top connected to the windlass, its short arm connected to the brake bar, which was nearest to the windlass; there being a connecting rod from the brake lever to the other brake bar, so that the other brake bar, through this rod, acted as a fulcrum of that lever. Batchelder and Thomson found that arrangement in operation in the trucks, and they turned the trucks round, so to speak, or shifted the lever from the outside of the truck to the inside of the truck. In all other respects *the operation of the lever within the truck* remained the same as before. It was still attached by its short arm to one brake bar, and by its fulcrum to the other brake-bar; but it was no longer attached to the windlass. They introduced a center lever, attached to the body of the car, and the arms of this center lever were connected with the windlasses at either end—one arm to one windlass, the other arm to the other windlass; and they also connected this center lever with each brake-lever in such manner that when the center lever was acted upon by either windlass, *it received the power of the windlass and distributed it between the trucks*, sending one part of the power to one truck and the other part of the power to the other truck, and that power when sent to the several trucks was received on the brake-lever of each truck, which was thus actuated through the center lever instead of being actuated, as they were before, by the direct action of the windlass. This shows the structure and operation of what Batchelder and Thompson did.

Now this structure and mode of operation were attended with certain defects. First of all, as is apparent must be the case, the attachment of the brake-lever by its short arm to one brake bar and by its fulcrum to the other brake-bar necessarily exerts upon the different brake-bars unequal forces. That exerted by the fulcrum of the lever must be equal to that which is exerted by the windlass and by the short arm, inasmuch as it sustains both powers or weights, or whatever you choose to consider them. There was therefore introduced by means of this arrangement this inequality, so that a very much greater amount of power was thrown upon one pair of wheels in the truck than was thrown upon the other pair of wheels.

But this was not all, nor is it perhaps the most serious difficulty, though one of no trifling character. The center lever, as I have already stated, received and transmitted all the power, and distributed it between the two trucks; this center lever is attached to the body of the car by a bolt; of course when one of its arms is prevented from vibrating the other arm is prevented from vibrating. Now suppose the set of shoes in one truck is but little worn, and the set of shoes in the other truck is more worn; that they are unequally worn in the different trucks; when the brakes are set up, by the windlass, the center lever, distributing the power of the windlass to the brakes which are less worn, brings them in contact with the wheel, and as soon as they come in contact with the wheel, the other arm of the lever cannot move, and therefore it cannot move its brake-bar up, so as to apply the more worn shoes to the wheels in that truck at all; and this is attributable to and necessarily follows, as your Honor sees, from the fact that there is a *permanent fixed connection by a bolt between this distributing lever in the center and the body of the car*, which bolt is the *point of resistance of the whole system.*

There is another difficulty also arising out of this arrangement, and that is, that when the brakes are set up, and while they are thus set up, if the cars strike a curve, striking the curve causes the trucks to swivel; they change their relative position to this center lever, which cannot change its position, owing to the fact that it is attached to the body of the car by this fixed bolt, and that both or one of its arms is fixed in its position by the brake which is in contact with the wheels at the time. The trucks change their relative position to this center lever, and the consequence of it is, that the shoes in one truck are brought nearer to the end of the center lever, and greater pressure is thus exerted upon them; whereas, the other set of trucks are thrown further off and less pressure is brought to bear upon them, so that in going from a straight track and striking a curve with the brakes set up, or from a curve to a straight track, so that the relative position of the trucks and the center lever, which existed when the brakes were set up, is changed by reason of the swiveling of the trucks; then comes this difficulty, that you throw an increased force on one of the trucks, and you take off the brakes altogether, or mainly from the other truck, and that, too, at the moment when it is most essential that there should be nothing unsteady or abnormal in the operation of the trucks. Now these defects, which I have thus pointed out, are the necessary results or incidents of the mode of construction and operation, which was adopted.

Let us now turn to the other, the Stevens. We find that Stevens did not turn the trucks round. He retained the outside brake-lever, in its connection with the windlass, and he retained it in its connection with the windlass by the short arm of that lever; but he did not connect that lever with the opposite brake-bar, to act as a fulcrum of that lever, as was done in the old form, and was adopted by these patentees.

He connected that lever with a second brake-lever *which he introduced into the truck*, and that second brake lever, introduced into the truck, had its short arm of the same length as the lever connected with its brake-bar. So that your Honor perceives that, having done that to both the trucks, *he had a different system inside each of the trucks.* Your honor will bear in mind that the problem which we are discussing here is *the mode of connection of the* brakes in two trucks. The things to be connected are the brake-system in one truck with the brake-system in another truck. Now, Stevens began by *modifying the brake-systems in the trucks;* not in form merely, because, as your Honor perceives, by using these two levers in the trucks he gets an equality of force on the wheels. He does not rely upon the brake-bar as the fulcrum of this single lever, and thus throw much greater power upon that set of wheels than was thrown by the short arm of the lever upon the other set, but he has introduced a second lever with a second short arm, to exert the same power on that brake-bar that is exerted by the first lever upon its brake-bar; and if you suppose no connection to exist whatever between the trucks, suppose there is no connecting-rod, and they are to be operated after the old fashion, by two brakemen, one at each end and each acting on the windlass, it is a different thing from what existed before—a substantially different thing. Before, there was inequality of force thrown upon the wheels; now, by this new arrangement of levers, and by getting these new attachments, he has made an equality of force. What next, may it please your Honor? Why, having thus modified the leverage in the trucks, he had nothing else in the world to do but *to connect the two systems together*, *not by a center lever attached to the car*, but by a rod, and that was done :and then the whole thing exists. I have already shown how he got the equality of force *in the trucks.* Now, by means of this rod, *not by a center lever*, *he gets equality of force between the trucks.* But, as your Honor will perceive, in the case of Batchelder & Thompson, they have a center lever there, the office of which center lever is to receive the whole power and *distribute it between the trucks;* the office of this rod is nothing in the world but to transmit the power—the whole power that is sent onward, transmitted to the next pair of levers—and it is not only therefore a different structure—there is not only employed a rod, a straight rod, in the place of a center lever—but the function of that rod is different from the function of the center lever; and so when you go to the next truck you find the power applied on the wheels with the same force on each pair, so that throughout the whole arrangement there is equality of force; and when you come to the inequality of the wear of the brake-shoes, owing to the mode in which he has modified the leverage *in* the trucks and *the mode in which he has connected that leverage by a rod*, *a floating rod*, so to speak, there is no difficulty in breaking up the unequally worn shoes so that they will bear upon the wheels in going from a straight line to a curve, or from a curve to a straight line; there is no difficulty owing to this change of position of the different brakes relatively to each other, *because there is no fixed lever interposed whose relation to them renders it necessary that it should change as they change* in order to make the power equal on the trucks or keep it equal. When the trucks swivel, this rod swivels with them. It is a loose system, so to speak, instead of being attached to the body of a car by a bolt in such a rigid manner that it cannot yield when going from a straight line to a curve, or from a curve to a straight line.

Well, may it please your Honor, if these things be so, then isn't it true, in point of fact, that when we come to compare one of these systems with the other, we find, in the first place, that the *construction of one* is different from the construction of the other; that the *number* of parts is not the same; the *positions* of the parts are not the same; the *functions* of the parts are not the same; the *effect* of each part and the *effects of the whole* are not the same, And if this be true —and I see no possible escape from it—then is it, or can it, also be true that one of these two things is substantially the same as the other—that one is a mere colorable copy of the other—for your Honor will remember the rule laid down, that inasmuch as these patentees only had this narrow field of devising *some particular way* to make this connection between the two trucks, they could hold their way, but nothing outside of it. *They must show that this thing complained of includes substantially the same thing as the thing they* have made and patented; but can it include substantially the same thing when theirs is one system and *the defendant's is throughout a different system*—different in its structure, different in its functions, different in its mode of operation, different in its effects? When there is no one part in the Batchelder and Thompson which is found in form, position, functions, or effect, like any corresponding or other part in the Stevens, I respectfully submit it is a legal impossibility that one of those things should infringe upon the other when the patent is construed in the manner I have endeavored to show it should be.

I do not understand from the very brief opening which was made yesterday that the learned counsel on the other side would attempt to controvert these views, provided the patent is to receive the construction we contend for. If when this patentee says in his summing up, "what is claimed by us is, to so combine the brakes of the two trucks with the operative windlasses or their equivalents at both ends of the car by means of a vibrating lever or its equivalent, or mechanism essentially as specified, as to enable the brakeman," &c., he is understood to claim his *described system* of connecting the two trucks; if that is the meaning and legal effect of it, then a comparison of the two systems shows ours is not substantially the same as what is here described and claimed. But, says the learned counsel, this claim covers a wider field; the proper construction of this claim is such that it covers not only the particular method described, of making connections of the system described by means of the center lever as described, but it covers any method of making any connection of any system *by leverage power*. That is his claim, and I do not see how he can stop short of it. The moment you come to inquire whether the two things are substantially alike *viewed as units*, viewed as a whole, it is manifest they are not alike; therefore they fix upon this similar feature in the two, not that both connect by a lever, for we do not, but that *both employ lever power*, and out of that similarity is to be constructed a sufficiently broad foundation on which to rest a decree of infringement; simply because each employs in his way one of the elementary powers in mechanics; because we employed in our own way, and in a substantially different way from theirs, the same elementary power in mechanics, obtaining thereby different results from theirs, that therefore we infringe the patent; as if this patent had been taken out to read, "What we claim as our invention and seek to patent is, combining the brakes of two trucks with the operative windlasses, or their equivalents, at both ends of the car by means of the vibrating lever A, or its equivalent, or mechanism essentially as specified, *or any other mechanism, no matter what it is, provided lever power is employed*"—not in making the connection, but in any manner—I respectfully submit that if they will modify their patent in that way, it will stand but a very short time—only long enough to receive a proper degree of judicial consideration. I look upon this patent, may it please your Honor, as being what it purports to be, a patent *for a particularly described method of connecting a described system of leverage in the trucks.* If ours is substantially the same, we infringe it; if ours is substantially different in its construction, in its mode of operation, and in its effects, we do not infringe it; and that ours is thus different, I think, cannot be doubted.

May it please your Honor, it does seem to me that this Court has decided this question already. When the validity of the Stevens patent was in issue before your Honor, this Batchelder and Thompson patent was relied upon as anticipating it, and your Honor decided it did not, because it did not cover the same invention; as appears from your Honor's opinion in the 2d Fisher's R., it was held that the Stevens patent was for a different combination from that shown by Batchelder and Thompson. The opinion, as here published, or rather the results of the opinion, do not contain any of the reasoning of the Court upon the subject, and therefore I am obliged to presume that your Honor went through an examination and comparison of the different parts of this machine, similar to the one that I have endeavored to present to the Court; and that the result of that examination and comparison was, that the one viewed as a unit was substantially different from the other. If that be so, then their patent cannot be infringed. If they have a patent for one particular mode of connecting the two trucks, and we have a patent for another mode of connecting the two trucks, and the Court has come to the conclusion that one is substantially different from the ohter, what remains to them? Why, it remains to them only to show that that other is substantially different, because, although it has borrowed the whole of their arrangement, it has added something to it. That is the only remaining inquiry. There are only two possible suppositions; one is that we have made a combination of our own which does not include theirs; the other is that we have made a combination of our own which does not include theirs, *but has added something to it.* I have endeavored to show your Honor that *each is a unit*, that *there is no possibility of conceiving of any addition or subtraction.* The two things are wholly unlike from beginning to end. Each is a system wholly unlike the other. You cannot possibly start and advance up to a certain point and say, "To this point Batchelder and Thompson have gone, and the rest Stevens did." Stevens did the whole or he did nothing. Viewed as a system, either this is wholly new, or else it is wholly old, because it is like Batchelder and Thompson's, and this Court has decided that it was not anticipated by Batchelder and Thompson, that it is a different combination; not using the word combination technically, but as describing an organized whole. I respectfully submit there is no escape from the conclusion that it does not infringe this patent of Batchelder and Thompson.

I believe, may it please your Honor, that these are all the observations I deem it necessary to address to the Court. Thanking your Honor for your kind attention, I will cease to task your patience further.

[illegible]

Supreme Court of the United States.

THE CHICAGO AND NORTHWESTERN RAILROAD COMPANY,
Appellant,
vs.
THOMAS SAYLES.

BRIEF FOR APPELLEE.

Review of the Litigation.

A summary, however brief, of the litigation which has been had on the patent involved in this case necessitates mention of what is known as the "Albany trial." That was a suit brought by Tanner, the patentee, within a few months after the patent was granted, against The New York and Erie Railroad Company for infringement. Tanner also brought a similar suit against The Hudson River Railroad Company about the same time. These two Corporations united to resist the patent, and the suit against the Erie Road was tried. The trial took place at Albany, before Judge N. K. Hall and a jury, in October, 1854. Eminent counsel were engaged in it on the part of the infringers ; and the brakes known as the "Springfield Brake," the "Nichols Brake," and the "Stanley" or "Stanley-Talson Brake," were set up against the novelty of the invention. The question whether the "Stevens" brake—which is the form of infringement used by the present appellants—was a violation of the patent, was also one of the issues in that case. The trial ended in a verdict that the patent was valid, and that the Stevens brake infringed it. (Bill—Printed Record, p. 7.)

But the "Millholland" brake was not before that Court, and consequently other infringers claimed that it was a defense. And when Sayles sued these appellants, they set it up. (Answer—Record, p. 29.)

The present suit was brought on the 28th of December, 1861, but in consequence of delays in the lower Court a decree was not made in it until 1875. After this, the appellants claimed to have discovered an entirely new defense —the alleged "Tyler Car"—and to have obtained fresh light on an old one the "Stanley-Talson" brake—and the Court below was persuaded to set aside the decree mentioned and let the appellants set up these further matters. A long time was unavoidably consumed in completing the proofs on them, and the cause in its new aspect could not be brought to hearing in the Circuit Court until May, 1869. That Court delayed its decision two years and two months, so that the second interlocutory decree could not be entered until July, 1871.

A persistent contest then ensued before the Master, but his Report was filed July 31st, 1873, whereupon another delay of about a year and a half was made by the Circuit Judge in passing on the Exceptions and other efforts of the appellants to rid themselves of the amount reported against them.

It is for these reasons that the final decree from which this appeal comes up was not entered until September, 1875.

Special attention is asked to the fact that the appellants were well acquainted with the Albany trial, the issues in it and the result of it, (Answer—Record, p. 28), and that not until the *second* hearing in this case, in May, 1869, did they—beaten on all other points as up to that time they were—raise the question that they had not infringed the patent.

The Invention which Batchelder and Thompson made Defined.

Batchelder and Thompson invented the first successful "Double-acting Car-Brake."

A double-acting brake is a mechanism for stopping a railroad car by which a brakeman can apply the brake-shoes simultaneously to all the wheels of one car from either end of the car.

To ascertain the precise addition which they made to the railroad system, the first inquiry necessary is as to the state of the art prior to October, 1846, when their invention was completed.

Railroad cars are unavoidably of great weight, and when run in trains at locomotive speed the inertia of the moving mass is so great that the locotive with its steam entirely shut off is insufficient to present the required resistance to stop the train within a reasonably short distance at the various stopping places along the line of road, or to avoid collisions or other disasters when impediments are noticed on the track by the engineer. It is therefore necessary to apply friction to the periphery of the wheels to impede their turning, and thereby present sufficient resistance to stop the train within the shortest practical space—the shorter the better provided it be not too sudden to injure the cars.

The mechanism by which friction is applied to the wheels of a car for this purpose is termed a railroad car brake. Friction is made against the periphery of the wheels by blocks of wood or iron, termed shoes, in the form of segments fitting the periphery of the wheels, and so connected with each other and with a windlass or lever on the platforms of the car that the brakeman, stationed on the platform of the car, can at a given signal, such as a sharp whistle of the locomotive, operate the windlass or lever on the platform and thereby force the shoes or segments into contact with the periphery of the wheels.

For a long time in the use of railroads, the cars were on four wheels, with the two axles parallel, the wheels being permanently attached in pairs to, and turning with, the axles. The earliest of these cars had no brakes at all. Trains were stopped at first by inertia, then, as the next step, by the locomotive. As the railroad system advanced, brakes were employed, but for a long time the friction shoes applied to only one pair of wheels. Afterwards, the shoes were attached in pairs to each of two "brake-beams" or "brake-bars," and these latter were suitably hinged to the frame of the car and suspended on one side of the pairs of wheels, and were connected with each other and with the windlass on the platform, so as to enable the brakeman by operating the windlass to force the two pairs of shoes into contact with the two pairs of wheels at the same time.

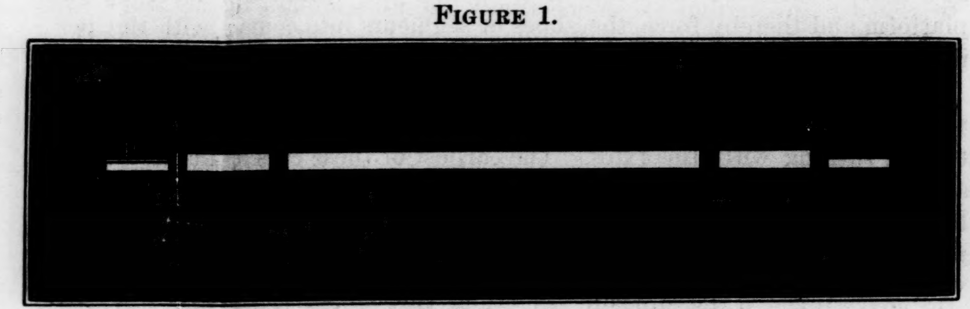
In the progress of improvement the mode of construction of railroad cars was changed. Four-wheeled cars were found to be ill adapted to our system of curved roads, and thereupon cars were, and are now almost universally, constructed to run on eight wheels. Two four-wheeled trucks or bearing carriages are connected each by a central or king-bolt with, and near the ends of, a long car body, so that they can turn freely under it to follow the curvatures of the road. The two axles in each of the two bearing carriages are always parallel, but the axles of either of the bearing carriages are only parallel with the axles of the other bearing carriage when the car is running on the straight portions of the track. At all other times they are not parallel, but are constantly changing their relations to each other as the curvature of the road varies.

It is important to bear in mind the above peculiarity of the double truck eight-wheeled cars used upon our railroads, for the invention at issue relates to a mechanism intended to apply friction simultaneously to all these eight wheels from either end of the car.

When eight-wheeled cars were first introduced, and for several years thereafter, the brakes for making friction on the wheels were applied as they had been at first applied to four-wheeled cars—that is to say, on only the wheels at one end of the car; the sole difference being that while in the four-wheeled cars there could be but one pair of wheels towards one end of the car, so that when the brakes were applied at only that end they could make friction on only one *pair* of wheels, in the eight-wheeled car there is a *truck* containing *two* pairs of wheels at each end of the car, so that when the brakes were applied at one end they could make friction upon two pairs of wheels. In other words, the earliest eight-wheel cars applied the brakes to as many wheels as the four-wheel cars did in the latest condition of the latter, but they still applied to only one end.

Figure 1 is an accurate representation of one of these early eight-wheel cars.

FIGURE 1.

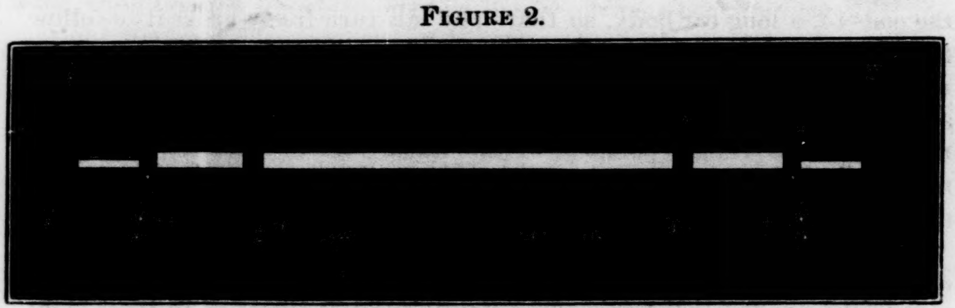


The Old Single Brake—on One Truck.

In this Figure the friction shoes are shown at s, the brake-bars at b, the rod which connected the two brake-bars, at o, and the windlass, the chain and rod, and the lever, by which the brakeman forced the two pairs of shoes into contact with the wheels, at W, r, and L, respectively. P represents the car platform, and B the long car body.

By degrees, however, this same arrangement was duplicated at the other end of the car, as seen in Figure 2.

FIGURE 2.



The Old Single Brake—on Both Trucks.

But still the brakes at each end of the car were applied separately, and independently of each other. For this reason they were termed "single" brakes, because operating on only a single truck, and it is obvious that to apply all the brakes of such a car simultaneously, there must be a brakeman at each end of the car when only one car was run. But when two cars were run in a train, three brakemen were required, one at the front end of the forward car, a second at the rear end of the rear car, and a third between the two cars, who, after operating and securing the windlass of one of the cars, would pass to the adjacent platform of the other car and there perform the like operation. And in that proportion brakemen were needed for trains of any other number of cars.

Besides requiring so many men, these single brakes had an inherent controlling defect.

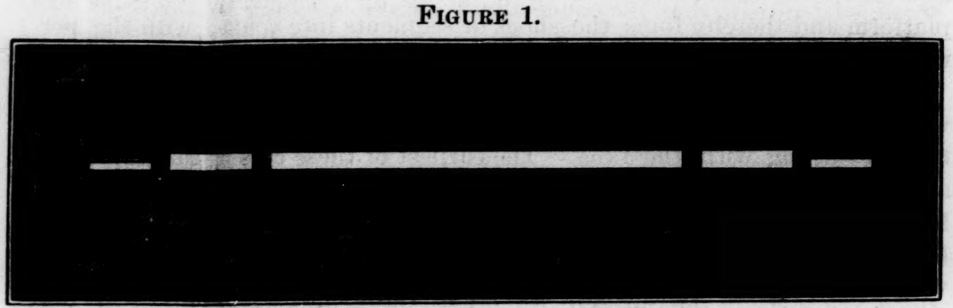
The windlasses of an eight-wheel car are necessarily placed on one side of the longitudinal centre line of the car. This is done that they may not interfere with the central passage way through the cars and through the train. It is also requisite that the connection from the windlass to the truck lever of the single brake should be in a line parallel or nearly so to the length of the car, in order that the truck lever may work properly. Hence any swiveling of the truck on curves would change the relation of the top of the truck lever—which is attached to the truck—to the windlass which is attached to the body of the car, so that when the brake is applied and the car passes over a curve which turns in one direction, this connection would be so much loosened as to materially slacken the pressure of the brake shoes on the wheels and thereby prevent the brake from acting efficiently; and if the curve turns in the opposite direction, the connection would be so much tightened as to cause the shoes to grip the wheels so closely that they would slide on the track, and when that occurs not only are the wheels injured but the brake becomes of no use, and the car can only be stopped when its momentum is spent. When—as is often the case—the curve is a "reverse" one, like the letter S, one end of the car as it reaches the beginning of the curve will have its brake loosened, while at the other end not yet off the straight track the brake will be properly applied; and by the time this rear end reaches the curve and its brake becomes loosened, the forward end will reach the end of the curve and turning in the opposite direction will have its brake so tightened that the wheels will slide. It was impossible to proportion the parts of the single brake in any manner which would prevent these difficulties.

The employment of so many brakemen, with the single brake, especially on roads doing a large business, was a source of expense, and it naturally became a desideratum to reduce the number, and at the same time have the cars braked more efficiently. The problem to be solved was to connect the brakes of the two four-wheel trucks, notwithstanding their constant change of parallelism with each other and with the windlasses at both ends of a car, in such a manner that a brakeman at either end of the car could at one operation apply the four pairs of shoes to the four pairs of wheels of one car and insure the making friction on all of them simultaneously. This problem, when solved, would materially reduce the number of brakemen needed and thereby materially reduce the expense of running trains. For a single car but one brakeman would be required, instead of two; for a train of two cars but one would be required, instead of three—for being placed between the two cars he could after operating one windlass to make friction on the eight wheels of one car, pass to the other platform and make friction on the eight wheels of the other car; for a train of four cars but two brakemen would be required—one between the first and second cars and the other between the third and fourth cars; and in that proportion for any number of cars.

Such was the problem to be solved, and such the inducement which commended it to ingenious men. That many unsuccessful attempts were made

Figure 1 is an accurate representation of one of these early eight-wheel cars.

FIGURE 1.

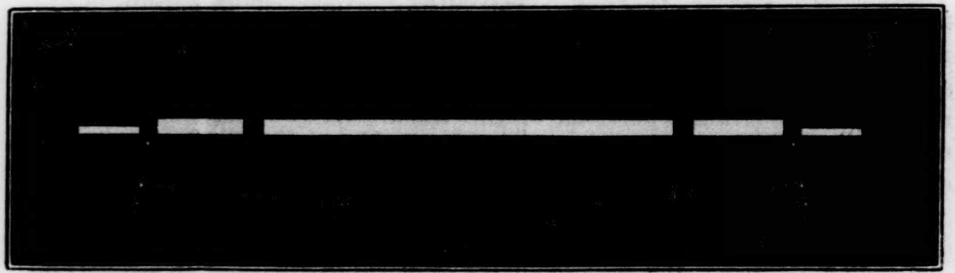


The Old Single Brake—on One Truck.

In this Figure the friction shoes are shown at s, the brake-bars at b, the rod which connected the two brake-bars, at o, and the windlass, the chain and rod, and the lever, by which the brakeman forced the two pairs of shoes into contact with the wheels, at W, r, and L, respectively. P represents the car platform, and B the long car body.

By degrees, however, this same arrangement was duplicated at the other end of the car, as seen in Figure 2.

FIGURE 2.



The Old Single Brake—on Both Trucks.

But still the brakes at each end of the car were applied separately, and independently of each other. For this reason they were termed "single" brakes, because operating on only a single truck, and it is obvious that to apply all the brakes of such a car simultaneously, there must be a brakeman at each end of the car when only one car was run. But when two cars were run in a train, three brakemen were required, one at the front end of the forward car, a second at the rear end of the rear car, and a third between the two cars, who, after operating and securing the windlass of one of the cars, would pass to the adjacent platform of the other car and there perform the like operation. And in that proportion brakemen were needed for trains of any other number of cars.

Besides requiring so many men, these single brakes had an inherent controlling defect.

The windlasses of an eight-wheel car are necessarily placed on one side of the longitudinal centre line of the car. This is done that they may not interfere with the central passage way through the cars and through the train. It is also requisite that the connection from the windlass to the truck lever of the single brake should be in a line parallel or nearly so to the length of the car, in order that the truck lever may work properly. Hence any swiveling of the truck on curves would change the relation of the top of the truck lever—which is attached to the truck—to the windlass which is attached to the body of the car, so that when the brake is applied and the car passes over a curve which turns in one direction, this connection would be so much loosened as to materially slacken the pressure of the brake shoes on the wheels and thereby prevent the brake from acting efficiently; and if the curve turns in the opposite direction, the connection would be so much tightened as to cause the shoes to grip the wheels so closely that they would slide on the track, and when that occurs not only are the wheels injured but the brake becomes of no use, and the car can only be stopped when its momentum is spent. When—as is often the case—the curve is a "reverse" one, like the letter S, one end of the car as it reaches the beginning of the curve will have its brake loosened, while at the other end not yet off the straight track the brake will be properly applied; and by the time this rear end reaches the curve and its brake becomes loosened, the forward end will reach the end of the curve and turning in the opposite direction will have its brake so tightened that the wheels will slide. It was impossible to proportion the parts of the single brake in any manner which would prevent these difficulties.

The employment of so many brakemen, with the single brake, especially on roads doing a large business, was a source of expense, and it naturally became a desideratum to reduce the number, and at the same time have the cars braked more efficiently. The problem to be solved was to connect the brakes of the two four-wheel trucks, notwithstanding their constant change of parallelism with each other and with the windlasses at both ends of a car, in such a manner that a brakeman at either end of the car could at one operation apply the four pairs of shoes to the four pairs of wheels of one car and insure the making friction on all of them simultaneously. This problem, when solved, would materially reduce the number of brakemen needed and thereby materially reduce the expense of running trains. For a single car but one brakeman would be required, instead of two; for a train of two cars but one would be required, instead of three—for being placed between the two cars he could after operating one windlass to make friction on the eight wheels of one car, pass to the other platform and make friction on the eight wheels of the other car; for a train of four cars but two brakemen would be required—one between the first and second cars and the other between the third and fourth cars; and in that proportion for any number of cars.

Such was the problem to be solved, and such the inducement which commended it to ingenious men. That many unsuccessful attempts were made before it was successfully solved will become apparent to the court from the evidence in this case.

The task at first view appears an easy one. In point of fact it was very difficult.

The difficulty arose mainly out of the complicated conditions under which car brakes must in actual practice be used, in consequence of the frequent swiveling of the car trucks caused by the curves in the railroads. It was increased by the high speed at which passenger trains must be run, and the frequent stops which they must make.

In England this difficulty would not have existed to anything like the same extent that it did in this country, because there, owing to the greater accumulation of capital, larger sums were at the disposal of railroad projectors, and railroads were built more like the engineer's ideally perfect road—that is, as near to a straight line as possible. A high authority says: "An English road was virtually a straight road; an American road had curves sometimes of as small a radius as 200 feet." But to build the English railroads straight involved vast expense, for natural obstacles had to be overcome—hills to be tunneled or cut through, valleys to be filled up or crossed at great height, morasses to be made solid ground, and all the resources of the most eminent constructors—the Brunels, the Stephensons and the Rennies—resorted to In this country capital was less abundant, populations in many sections were sparse, natural obstacles—except in the prairie States—were greater, and the lines were of necessity much longer. To build as cheaply as possible was the first requirement, for the country had to be developed and the hoped-for business of the road created. Hence the engineers laid out the lines around the hills and mountains instead of through them, and made many a *detour* because it was cheaper than the costly structures which would have made straight routes possible. A striking instance of this is the well known "Horseshoe Bend" on the Pennsylvania Railroad. In Great Britain, deep valleys such as those at that spot would have been crossed by magnificent viaducts like that at Congleton, or like the longest piece of railroad masonry in the world, the Ballochmyle Viaduct on the Glasgow and South-Western Railway. Here, the very able engineer who constructed the Pennsylvania Road, lengthened his line by miles and wound it round and round the mountain till in more than one place it doubles on itself—producing the "Horseshoe Bend"—that he might avoid the expense of making it straight by crossing the valleys directly. On many railroads in this country travel is made specially disagreeable by the constant curves which the cars have to pass over, so that if a passenger leaves his seat he finds it to be an achievement to keep his balance. Examples of such roads are the Central Ohio, the Pennsylvania Central, the Northern Central, and the Baltimore and Ohio.

It was under such conditions, coupled with the difficulties arising from high speeds and frequent stops, that the problem of a successful double brake for eight-wheel cars had to be worked out.

It is strenuously insisted by the defendants that a double brake is merely two single brakes connected together. At a first glance this might seem to be so, and that to do it was all that was necessary to make a double brake But such a view is quite erroneous. It is impossible to make a successful double brake by merely connecting two single brakes. Such an effort was made in the "Springfield Crate Car Brake" and failed, some years before Batchelder and Thompson entered this field of invention. That brake was specifically two single brakes connected to the same windlass shaft. It is accurately represented in Figure 3.

FIGURE 3.

The Springfield "Crate Car" Brake.

It will be seen that a short chain, c, and a longer chain above it with a rod attached to the latter, run from each windlass, one to one single brake and the other to the other single brake of the car. Hence the brakeman when he operates the windlass would apparently apply both these single brakes simultaneously. This might possibly be so in fact, if the Springfield car ran always on a *straight* railroad and never on a curved one. But no car can do that, and when the Springfield car went into actual use—on straight track and curves alike—the defects of the brake became of such serious consequence that, as will presently appear, they caused it to be abandoned and thrown aside as a hopeless failure.

A few words will make these defects plain. The two chains which connected each of the windlasses with the two single brakes have been pointed out. In practice it was found that when attempts were made to apply the brake, these double chains would override each other so much on each windlass *as to prevent the brake from operating*. Besides this, as the chains were necessarily of unequal lengths, because one went to the truck nearest to the windlass whence it started—and was consequently quite short, only about fourteen inches—while the other went to the truck at the other end of the car, so that it was quite long, it resulted that if the chains were adjusted to apply both systems of brakes *on a straight track*, the short chain would prevent the car from running on a curve, and would, sometimes, hold the car so firmly as to throw it off the track on reaching a curved part of the railroad; and if they were adjusted *to a curve*, then the brakes could not be applied *on a straight track!*

Ephraim Harris, the inventor of this brake, has been examined as a witness in this case, and it will be instructive to refer to what he says about it.

At pages 86 and 87 of the Record, he testifies as follows:

> "*Q.* Was said brake in use on cars? if so, on what cars, for how long time, and how did it work? Explain fully."
>
> "*A.* Said brake was in use on cars for part of two years. *It did not give satisfaction in working.*"
>
> "We had two long crate cars running from Springfield to Albany; at Albany the road descended towards the river; this crate car then had a single brake on it, and running down to the river to unload the cars the brakeman undertook to brake up the car and the chain broke, and before he could get to the other end of the car to brake, the car ran into the river."
>
> "Mr. Gray, then superintendent of the Western Road, wanted I should put something on the car—an attachment put on the car—whereby the brakeman, if the chain broke, would have command of the other truck to brake it; and I arranged a car the same as this model, and on arranging it in this way, *we found considerable difficulty in winding the two chains on the windlass;* they would over ride, *and even so much as to destroy the power of the brake on the car entirely;* the first lever from the windlass was something like fourteen (14) inches; being that distance, if the chains were adjugted so as to brake both trucks at a time (I mean to apply on a straight track), the short chain would prevent the car from turning on a curve; these chains had to be altered, or lengthened, to accommodate the curves of the road."
>
> "The brakeman and conductor on the cars found considerable difficulty and fault in their operation."
>
> "The car had been thrown from the track in consequence of the short chain not allowing the truck to accomodate itself to the curves."
>
> "*This brake, at the time it was put on, was not intended to brake both ends of the car at once; it was put on in case the short chain broke, that the brakeman might have the use of the other.*"
>
> "The crate cars were switched from the main track, and were run down towards the river to unload their contents into the boat, and this attachment of the brake was put upon these cars to prevent them running into the river."
>
> "On the last car the brake was put on—the second car—I put a swivel joint on the long rods, for lengthening or shortening the same; that did not improve the brake at all."
>
> "*These brakes were in use part of two summers; the cars were then thrown aside for a while, and then rebuilt.*"
>
> "*The brakemen considered they could handle the car better* WITH THE SINGLE BRAKE."
>
> *Cross-examined:*
>
> "*Q.* You say the brakeman and conductor said they could handle the car better with the single brake; did they not, on this brake, have all the advantages of a single brake? If not, why not?"
>
> "*A.* They did not, on this brake, have all the advantages of a single brake; the windlass that takes the chain couldn't be but about a certain length from the platform down; consequently it gave a short distance for two chains, and this long chain being the upper chain, and the lower chain having to be put so low on the windlass, many times the lower chain would toggle under the bottom of the windlass; then, in other instances, the upper chain, having to have some considerable slack to accommodate the operation, at the first turn of the windlass the upper chain would ride down upon the lower chain—overlap on the lower chain."

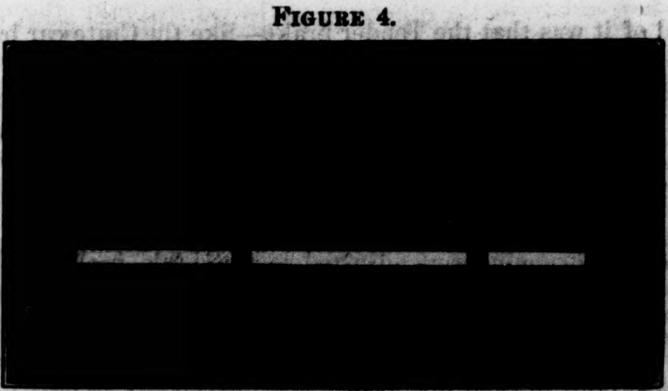
"*Re-direct:*"

"*Q.* When these cars were altered what kind of brake was pu; upon them?"

"*A.* A single brake; *this brake was abandoned and thrown out, and was never put on any other car while I was there*" (p. 88).

Previous to the form of Springfield brake thus disposed of by Harris, another one had been used on the same railroad on Tenders. A representation of this brake is given in Figure 4.

FIGURE 4.



The Springfield "Tender" Brake.

This device is even more specifically two single brakes connected together than the crate car brake was. In it the first rod r runs directly from the windlass to the brake lever of the first truck—just as in the original single brake shown in Figure 1—and the second rod r connects directly from that lever to the brake lever of the second truck.

Stress is laid by the defendants on the fact that this tender brake has continued in use. But there is nothing in this. It is not pretended by any of the witnesses that it has continued in use on anything except tenders. It could do so on them because, as will be seen in the picture, a tender is a short car—very short as compared with the long body of the modern eight wheel car—and consequently the defects of the brake do not on tenders produce such serious results, and also because the brakes on tenders are reqnired to be used but little.

If this tender brake is attempted to be employed on passenger cars, it at once discloses all the faults of the crate car brake and fails of success equally with that. This is because a passenger car is so much longer than a tender, and also because it requires to have its brakes used much oftener.

The case is not without positive proof to sustain this statement. About the year 1857—of course long after Batchelder and Thompson had successfully made their invention—the Western Railroad Company of Massachusetts, seeking to avoid liability for using the double brake, applied this tender brake to a large number of passenger cars belonging to the so-called "New York and Boston Express Line," and hence styled the "Line" cars.

These cars ran between New York and Boston, and the brake was kept on them for about eighteen months. How successful it was may be seen from the testimony of Hebron T. Douglass, a witness for the complainant and one of the master mechanics of repairs of the cars. He says:

> "The impression was general on the road that these brakes were not what they ought to be; they complained that they could not stop the trains.
>
> "*They used to run one car behind the train of cars which had the Springfield brakes on with a different brake on, for the reason that they did not consider it safe to run the cars alone with the Springfield brake.*" (*p.* 127).

The end of it was that the Tender brake—like the Crate car brake—was taken off these cars and the double brake put back in its place. And that is the last which has been heard of the Tender brake on passenger or "long" cars up to this hour. I believe it is not claimed on the other side that it worked well on these cars.

"The utter worthlessness of these Springfield brakes is well set forth in the testimony of Mr. Samuel Cooper, the highly intelligent expert who has been examined in this case by the complainant.

At page 107, he says:

> "This brake (the Springfield brake) would act successfully as a single acting brake, *but never as a double acting; if it were adjusted to operate on a straight track, it would not work upon a curve: and if adjusted for a curve, it would not operate upon a straight track.*"
>
> "The model itself shows this sufficiently; it would be fully as apparent upon an operating brake; and if the brakes were applied; for instance, upon a curve, or running upon a straight track, or upon a reversed curve, the chains would be liable to be broken or strained; but the chief objection to it is that it could not be adjusted both to straight tracks and curves."
>
> "*Int.* 10. If there was a swivel joint, or turn buckle, on the long rods to shorten or lengthen them, would that materially change your opinion of the brake?"
>
> "*A.* Not at all; it would enable you to adjust these rods but would not help the case on running from straight tracks to curve, or *vice versa.*"

And at page 112, he thus testifies:

> "*Int.* 26. Can the Springfield brake be so adjusted as to apply the brakes of both trucks at one and the same time *when the car is running on a straight track* and from either end of the car?"
>
> "*A.* I have not a doubt but that it can, and I have not a doubt but that if they were so applied, *and were to run upon a curve while they were so applied*—a thing which is done every day with car brakes—*the train would be exceedingly liable to jump the track* unless the chains were so light as to give way and by their breaking save the other catastrophe."
>
> "*Int.* 27. Please explain how such a catastrophe could take place as that of *throwing the train or the car from the track?*"
>
> "*A.* When the brakes were applied on the straight track the short chain to the adjacent lever was strained tight, dragging the truck as far round to one side as the flanges of the wheels would permit."

> "Now, if we run upon a curve which requires the truck to swivel in one direction, the brakes will be taken off by that motion perhaps at the moment when they are most required; *but if the curve turns in the other direction so as to swivel the trucks the other way, something must break or the car must go off the track, for the flanges are already hard up against the rail, and the truck, manifestly, can swivel no further so long as it remains on the rails.*"

It is entirely clear that a successful double brake is not to be sought by connecting together two single brakes.

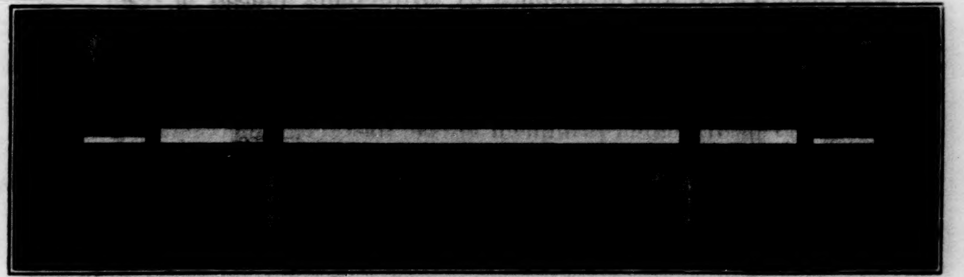
Other abortive efforts to invent a successful double brake appear in the case.

One of them was the "Millholland" brake.

Millholland was a practical railroad man, and at the time he got up his brake was Superintendent of Machinery on the Baltimore and Susquehanna Railroad.

A representation of this brake is given in Figure 5.

FIGURE 5.



The "Millholland" Brake.

The leading features of its construction were the "drum" arrangement D, underneath the car body, and the fixed points n, n, in the trucks—causing absolute rigidity throughout the system of connections of the brake levers, These two features together, as the testimony abundantly shows, made an abortion, mechanically—such a thing as was found by practical experience to be unable to be put to successful use upon railroads, and was therefore, as the proofs show, abandoned by the inventor himself and laid aside after one or two month's use. The reasons why it was unsuccessful are fully explained by Mr. Cooper, at page 107 of the Record. He testifies:

> "*Int.* 8. Please examine the model marked 'Millholland Model,' 'I, H.' and state what you find in the construction and arrangement of the brake shown in that model, if anything, that is calculated to prevent it from working practically and successfully when applied on railroad cars?"
>
> "*Ans.* There are two great defects in the brake shown by this model; first, the necessity of multiplying the power exerted by the man upon the windlass before it reaches the wheels is not here recognized; indeed, this power is divided up between the wheels, and is divided instead of being multiplied; the result would, doubtless, be that one man would exert an altogether insufficient force upon the brakes of a double

> truck car; the other objection is that there is no elasticity in the whole arrangement, all the pivots being rigid; if a single shoe were worn or lost all the force applied would be expended on a portion of the brakes, and, in my opinion, the brake could never be a practical one."
>
> "The drum in the centre is rigid and entirely unelastic; besides which, it has no effect to multiply the power transmitted from the windlass; but if this were the only defect it might be made to operate."
>
> "The chief defect, in my opinion, arises from the fact that the brake levers are also pivoted rigidly to the trucks; whereas in the Tanner brake they are suspended loosely from the truck, which gives an entire self-adjustability to the latter."
>
> "There are, in fact, in the Millholland, three entirely rigid points in the system of levers, *which, in my opinion, render the brake practically, and for any length of time, useless.*"

In the opinion of the Circuit Court this brake is fully considered, and the learned Judge says of it:

> "It is conceded—and the proof clearly shows—that it was never applied in any instance but upon one car, and I think it is clear that it was thrown aside and abandoned by Millholland himself in 1845."

In addition to the unsuccessful contrivances thus far mentioned as disclosed in the state of the art, the patent itself contains a disclaimer of two other brakes, one the "Griggs" brake and the other—though no name is given to it in the disclaimer—known to be the "Turner" bumper brake. But while the description in the disclaimer of each of these mechanisms is vague, it is apparent that they were merely "momentum" brakes—set in operation by the momentum of the moving train, and not actuated in any manner by means of windlasses. They were attempts to secure the application of brake shoes to all the wheels of a car, but not as *hand* brakes, and they are therefore outside the class of brake mechanisms to which the invention of Batchelder and Thompson belongs. It is not anywhere in the case pretended that they were successful, and no time need be spent on them. Enough has long been known of the requirements of a practical car brake to make it obvious that neither of them could answer the purpose.

The state of the art as Batchelder and Thompson found it has thus been presented. It is all which is disclosed by the testimony, and with a few immaterial exceptions, not of a character to enlarge it, all which existed. It is, so far as efforts at double-acting brakes are concerned, a record of failure. It demonstrates that the problem which Batchelder and Thompson undertook to work out was not an easy one. Practical railroad men—the projectors of the Springfield brakes, and Millholland, the foreman of railroad mechanics—had sought in vain to solve it, and Griggs, a veteran railroad expert and inventor, had deemed it wisest not to attempt to connect the brakes with the windlasses at all. By no one had a successful double-acting hand-brake been produced.

What Batchelder and Thompson Invented.

It has been seen that success was not to be found in connecting two single brakes together. A fundamental reorganization of the brake mechanisms known to the art was demanded.

FIRST—THE TRUCK BRAKE.

It will be remembered that the controlling defect of the old single brake and the two forms of the Springfield brake, was that the brake mechanism of the truck was wholly tied to the windlass, and that this organization of the parts was unaccompanied by any provision for enabling the brake connections to accommodate themselves to the swiveling of the trucks on curves. Batchelder and Thompson commenced, therefore, by modifying and reorganizing the single brake, and giving to it as thus modified a mode of operation different from what it had before, in order that it might be adapted to form a part of a double-acting mechanism.

To make more clear what they did in effecting this first step in their invention, the following Diagrams are presented.

DIAGRAM FIRST.

[redacted]

This diagram represents the arrangement of the old single brake, showing how all the brake connections of the truck—namely, the rod o, the lever L, and the rod and chain r—were tied to the windlass, with no provision for accommodation to curves.

DIAGRAM SECOND.

[redacted]

Diagram Second shows the manner in which Batchelder and Thompson modified this mechanism. That is to say, they first disconnected the rod r from the windlass and its chain, and then they turned the truck round, or reversed it, so that the brake rod r and lever L should be operated towards the centre of the car. In this way they formed their truck-brake. It was no longer the single brake because it was no longer connected with or operated by the windlass. To be the single brake, the truck connections must be attached to and be worked directly by the windlass. If it is otherwise, it is not the single brake. The direct connection to the windlass is as integral a part of the single brake as is the lever L or the rod o.

Having thus provided a truck-brake for each end of the car, which, by being freed from connection with the windlass, was adapted to conform to the curves of a railroad, the next step was to combine these independent truck-brakes with each other and then connect them with the windlasses.

SECOND—THE ADDITIONAL LEVER SYSTEM.

The object of the inventors was to produce a brake all the shoes of which could be applied simultaneously from either end of the car. Manifestly additional levers to those which formed part of the two truck-brakes must be introduced to accomplish this. Because the truck-brake levers—L and L′ in the diagrams—could do no more than work the brake shoes of their respective trucks against the wheels. When they had performed this function they had, so to speak, exhausted themselves. They had received power at one and applied it at the other of the only two points at which a *single* lever can do either. There could remain in neither of them any other operative points from which power or motion or a medium or connection could proceed either to the opposite truck-brake or to the windlasses. Thus, in Figure 6, L represents a lever such as is used for the truck lever of car-brakes and is seen in all the preceding figures, being in this example a lever of the second order, that is, one in which the weight or resistance is between the power and the fulcrum.

FIGURE 6.

Precisely such a lever as this is the lever of Batchelder and Thompson's truck-brake, and it is of course apparent that it has only three operative points, so to speak, that is, a power point, a fulcrum point, and a force point. To the power point must run the rod or rod and chain connection which works it, it must use the fulcrum point for the resistance without which it cannot work at all, and from the force point must extend the rod which connects it with the brake-bar at the opposite side of the truck. It can do nothing more for it is only *one* lever—a "*single*" lever.

There being at each end of the car—in the plan of the inventors—a truck-brake with such a lever in it, and the object being to connect these two independent truck-brakes with each other and with both the windlasses, it is clear that an additional lever or system of levers was needed to do it. If no further lever was used, the brake would be only the Springfield brake and would fail of success. But *two* additional levers, or a "double" lever—which is the equal and equivalent of two "single" levers—would combine both the truck-brakes together, and would connect them to both windlasses so that they could be operated from either end of the car.

Such a double lever—the equal of two additional single levers—Batchelder and Thompson introduced into their car, and the invention was complete. All the brake shoes could be simultaneously applied to the wheels from either end of the car; there was no tying of the two brake systems to the same windlass without provision for accommodation to curves—as in the Springfield brakes; and there was no system of rigid, fixed points throughout the mechanism—as in Millholland's contrivance. Freed by Batchelder and Thompson's invention from these defects, the brake at once became a practical success. It went into immediate use, and it has continued to be used up to the present hour.

The function of this double lever added by Batchelder and Thompson is important in more than one branch of this case. It may be denied that it *is* a double lever, and it will therefore be well to demonstrate here and now that it is.

This can be done at a glance by diagrams, and for the sake of showing it more clearly by contrasting a "single" lever with Batchelder and Thompson's lever, Figure 6 is here repeated.

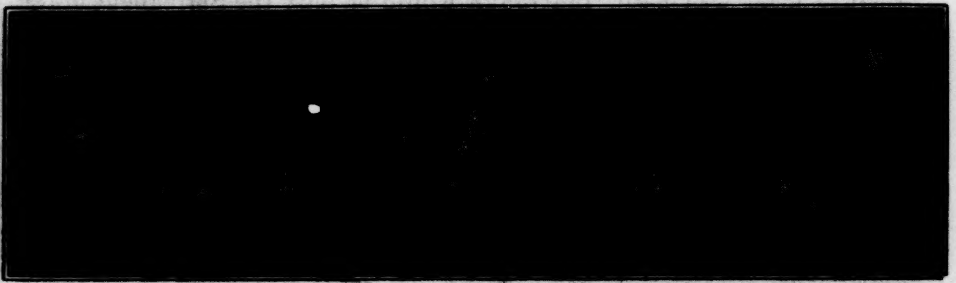
FIG. 6 Repeated.

FIG. 7.

A "single" lever, such as is represented in Figure 6 Repeated, has already been seen to have but three operative points—a power point, a fulcrum, and a force point. But Figure 7 is the Batchelder and Thompson lever—the double lever A′ of the patent—and it is obvious that it has *two* power points, *two* force points, and that its fulcrum is common to each half of it. In other words, it has double the number of operative points which a "single" lever has. It is therefore properly termed a "double" lever.

The next Figure—Figure 8—shows the mechanical relation of this added double lever to the already described truck brakes.

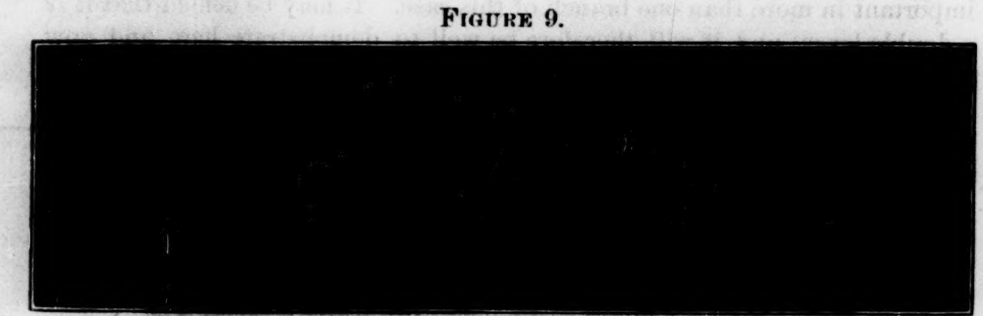
FIGURE 8.



The rods r and r′ have now only to be extended or produced out to the two points on the double lever A′ nearest to the centre or fulcrum and fastened there, and the chains of the windlasses W and W′ lengthened out by rods to the ends of the lever A′ and there secured, and the mechanism is complete.

Figure 9 shows these connections made.

FIGURE 9.



This form of the combination is that which is represented in the drawing of the patent.

It is thus apparent that the component parts of the invention, are, first, the truck brake, produced by modifying the old single brake and causing it to work towards the centre of the car; and, second, the double lever, or additional lever, to combine the two truck-brakes together and connect them both with both the windlasses.

The proper definition, therefore, of what Batchelder and Thompson invented—so far as respects their hand brake as shown in the patent—

is, that it was the combination of two truck-brakes—or, as may with equal accuracy be said, the two systems of brakes—arranged and operating as described, that is to say, disconnected from the windlasses and working towards the centre of the car, with each other and with the windlasses, by means of the additional lever system or double lever, in such manner that the brakes can be applied simultaneously to all the wheels from either end of the car.

This combination, at the date of their invention of it, was absolutely new in the art. The two leading elements of it, the truck-brakes disconnected from the windlasses and working to the additional levers, and the double lever system itself, were also entirely new elements in a car brake.

HISTORY OF THE MAKING AND TESTING OF THE INVENTION BY THE INVENTORS.

The testimony of the complainant's witnesses Asahel G. Batchelder, one of the inventors, and Albert J. Bellows, who assisted them in having the invention tested on the Fitchburg Railroad, respecting the matters which relate to this topic, is wholly uncontradicted. The appellants did not call a single witness on the subject. A synopsis of this testimony will therefore be a sufficiently satisfactory mode of putting the facts of this part of the case before the court.

Asahel G. Batchelder, pp. 92–99, testifies:

> That he became acquainted with L. F. Thompson, his co-inventor, in the Spring of 1846. That his attention was first called to the subject of railroad car brakes by Thompson showing him a model of a car brake. That soon after, they worked together of evenings, planning different kinds of brakes, and in October, 1846, they together invented and made drawings of a brake, from which he made a model during the following Winter, and finished it in January; it might be as late as February, 1847. That the model marked "Bachelder Model, E. Merwin, U. S. C." is the original model made at that time, and that the said model also had a bumper arrangement, not now on the model. That he made another model for the Patent Office in March or April, 1847, which was taken to Nathaniel Heath, at Boston, Mass., whom they employed as an agent to take out the patent, and who was to become interested in the patent. That they applied for a patent for it about the middle of June, 1847. That he and Dr. Bellows applied a brake on their plan on a car on the Fitchburg road, in Massachusetts, in October, 1847, and that it worked to their entire satisfaction. And that they applied another like it to a car on the Lowell road soon after. That it was put on at the expense of himself and Dr. Bellows, the companies merely doing the forging of the iron work. And that the construction of it for both roads was the same, and that the model marked "Fitchburg Model" represents the brake as it was put on the Fitchburg road.
>
> That the invention consisted of two parts, viz.: a brake to be worked by hand, and an arrangement by which it could be worked with the bumper by the inertia of the train.
>
> That their main object in the bumper arrangement was to apply the brakes to the front of a train by the hand arrangement, and thereby check the speed of the front car, so that the inertia of the rear cars would cause the bumpers to operate and apply the brakes to the wheels

> of the other cars, and thus stop the whole train. That both arrangements could be worked separately. That the witness considered the hand arrangement the most important, and that they intended that the patent should secure both arrangements, and so instructed their agent. That Heath made the application for the patent as their agent. That he was to pay the expenses of procuring the patent for an interest in the invention, and that he assured them that the patent would be granted in about six months.

This evidence clearly establishes the fact that the invention was made as early as October, 1846, at which time it was fully represented by drawings from which the complete model Exhibit "Bachelder Model" was made no later than the first of February, 1847, and was reduced to practice by being applied to a car on the Fitchburg road in the Fall of 1847.

Batchelder's testimony is corroborated by the witness Bellows, who says:

> That he first became acquainted with the double-acting brake invented by Bachelder and Thompson, by Thompson showing the model Exhibit "Bachelder Model," or one like it, either in the latter part of 1846 or in the first part of 1847. That some time after this he engaged to assist them in making a practical application of it to a car on the Fitchburg Railroad. That he became possessed of one-quarter interest in the invention on condition of defraying the expense of testing it; and that it was applied to the car on the Fitchburg road as represented in the model marked "Fitchburg Model." (pp. 89, 90).

This witness fixes the time of his first seeing the model of this brake by the fact that it was the Winter preceding the time of his writing a letter to a gentleman in the Fall of 1847, which letter related to the application of the brake on the Fitchburg road, which had then just been made. This letter he says was afterwards found in the records of the Patent Office. (p. 90.)

As the appellants introduced no testimony whatever to contradict these witnesses, the fact that the invention was completed in October, 1846, must be taken as indisputable in the case. Discussion of the appellants' efforts to show that prior to that time it had been made by others, does not come within the design of this Brief, as that portion of the argument will be made by my associate. I will therefore proceed with the topic under consideration.

It has already been seen by the testimony of Batchelder, that the model which is marked "Bachelder Model," and which was completed by the inventors as early as the first of February, 1847, was made by them from, and was like, the drawings which they finished in October, 1846. This model is before the court, and it shows that the form of the invention embodied in it is precisely the form which is described and represented in the patent.

In this model, as in the patent, the rods which form the connections between the windlasses at each end of the car and the centre double lever, and between this lever and the brake levers of the two trucks, operate by pulling.

Batchelder also states, (p. 93), that they tried the brake on a car on the Fitchburg Railroad in the Fall of the same year, 1847, and that it worked to their entire satisfaction. He says the model marked "Fitchburg Model" represents the precise arrangement as it was put on the Fitchburg car, and by referring to this model it will be seen that it represents identically the same arrangement as is shown in the patent. When either of the windlasses is turned it pulls the centre double lever by one of the two rods, and the centre lever in turn pulls the levers of the two trucks by the other two connecting rods.

But there is on this model, in addition to the arrangement above described, some others necessary to be understood. At each end of each car there is a sliding bar called a bumper and draw bar. These are the usual bars by which the cars are connected in a train, and which coming into contact are forced inwards by the inertia when the speed of the locomotive, or of the head car, is checked. The inner ends of these bumpers, when so forced inwards, strike against the truck levers of the brakes, and it follows that as soon as both of the bumpers are forced inwards all the brakes would be operated simultaneously to apply friction to the eight wheels; but when this operation is performed it is by the *pushing* of the truck levers by the bumpers, and each bumper operates the brakes of the truck with which it is connected. This method of working the truck levers by the bumpers is made able to effect its purpose because the connecting rods which run from the centre double lever to the truck levers, are sufficiently light and flexible to bend when the bumpers are moved inwards, and therefore the centre lever will not be operated by them.

There is still another arrangement on this model with which, by means of small side levers at each end of the car, the brakeman can push the upper ends of the truck levers laterally, so that they shall not be acted upon by the bumpers when backing the train. When so set, the whole mechanism is in a condition for operating all the brakes simultaneously by turning the windlass at either end of the car, and by the windlasses only—in which case all the rods operate by pulling.

From this it follows that the invention as reduced to practice on the Fitchburg Railroad, consisted of two inventions:

First—The invention precisely as it is described in the patent, consisting of the combination of the brakes of the two trucks by a central double lever and two rods, and the connection of the central lever by means of two other rods with the windlasses at both ends of the car, so that the turning of either windlass would apply all the brakes simultaneously, all the connecting rods acting by tensile force, that is, by pulling.

Second—An arrangement of bumpers which could be so set as to operate all the brakes by the inertia of the cars, leaving them free, however, to be operated by the hand windlasses; or the said truck levers could be so set that the bumpers would not act upon the brakes at all.

Batchelder further testifies that the next Summer after the test on the Fitchburg Road—that is, the Summer of 1848—they put the brake as it is shown in the "Fitchburg Model," including the bumper arrangement, on a car on the Lowell Railroad, at Lowell, (p. 93). This, therefore, constituted a second practical test of the hand-braking part of the invention in the same form in which it is represented in the patent.

It is thus apparent that the inventors used due diligence in perfecting their invention and reducing it to practice.

The patent was applied for on the 26th of June, 1847, and was granted on the 6th of July, 1852. During all this interval the inventors were doing all that, situated as the testimony proves they were, they could do to obtain it. And as the uncontradicted evidence is that the identity and continuity was unbroken between the form of the invention as it is represented in the patent, and that in which it was first embodied in the drawings made in October, 1846, and in which it was tested in the trials on the Fitchburg and Lowell Railroads, and as the proofs show clearly that the failure to obtain the patent until 1852 was wholly caused by delays in the Patent Office, and by the incompetence of Heath, the agent with whom they had contracted to apply for and secure the patent, it is submitted that under the established rules of law no forfeiture of their rights took place on account of the lapse of time from 1847 to 1852.

But this subject of legal forfeiture or abandonment in the aspect in which it is presented by the appellants, will be argued by my associate, and I shall therefore pass to what may be termed its *mechanical* aspect.

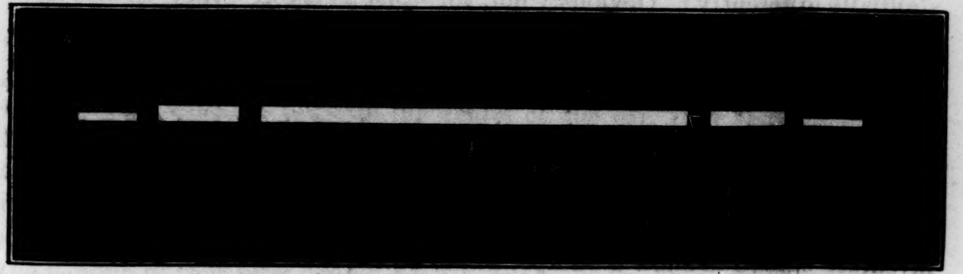
Substantial Identity of the June, 1847, Patent Office Application, and the Patent as granted.

Batchelder testifies, p. 93, that in March or April, 1847, he made another model—for the Patent Office—and carried it to Boston and left it with Heath, whom they had employed to take out the patent. This model he says, p. 94, Heath carried to the Patent Office, and he states that it was like the model which is in evidence marked "B. and T.'s P. O. Model, E. M."

The original application for the patent in June, 1847, described and represented the mode of application of the invention shown in this model sent to the Patent Office, instead of the mode of application shown in the first model made in January or February, 1847, and reduced to practice on the Fitchburg and Lowell Railroads. Between these two modes there are slight differences, and they are these:

First—The brake lever of each truck is not disconnected from the windlass, but notwithstanding this, the mode by which its connection with the windlass is applied causes the truck to be virtually turned round, as in the January, 1847 model, and in the patent, while the truck lever works towards the centre of the car, precisely as in that model and in the patent. This slight difference in arrangement will be readily understood from Figure 10.

FIGURE 10.



It will be seen that the connections J J from the windlasses to the truck levers LL pass around the shieves SS before being attached to the levers. But the variation due to this is of the most trifling consequence. It produces, so far as the operation of the truck lever is concerned, substantially the same result as if the lever was wholly disconnected from the windlass as it is in the January, 1847, model and in the patent. The object of disconnecting the lever is to free it from the inflexible attachment to the car body which destroyed the efficiency of the Springfield brake and the single brake, and enable it to accommodate itself readily to the swiveling of the truck. This same result the shieve arrangement accomplishes also, because the connections J J are flexible, as they must be to pass around the shieves, and as the truck lever is placed between the windlass and the shieve, the flexible connection must first be carried beyond it in order to be passed around the shieve and then be brought back to it, and this causes the connection to form a sort of *loop*, as seen in the Figure, before its extremity is attached to the lever. This provision enables the top of the lever to vibrate readily, or "float," as it is sometimes termed, to accommodate itself to every movement of the truck in swiveling. It is simply a slightly different way of doing the same thing that the inventors had in view in the January, 1847, model and in the patent when they disconnected the truck levers from the windlasses, while retaining the same underlying idea and causing the truck-brake to operate on precisely the same principle, because it is left *perfectly free to yield to the swiveling of the truck*, and *because it works towards the centre of the car*.

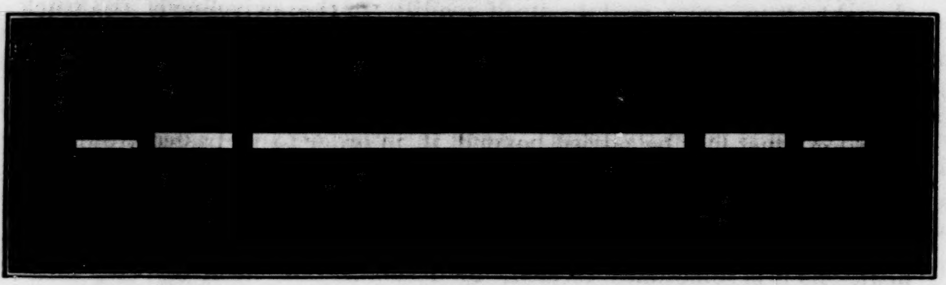
Second—Although the truck-brakes are combined by means of a central lever and rods so that they shall work together and in unison, these rods operate not by a pulling force but by pushing. This will be obvious on examination of Figure 10. But can this make any difference? The expert, Cooper, says that "the substitution of parts having a tensile strain for others having a thrust motion would be the simplest proposition that could be proposed to a mechanic." (p. 109). And it is apparent that it is so. Suppose the rods which in the January, 1847, model, and in the patent, run from the centre lever to the truck levers, were made to push, could it be seriously pretended that they had thereby become different rod and operated substantially differently? Obviously not, for—just as before—they would, with the centre lever, combine the two truck-brakes with each other and would enable them both to be operated simultaneously from either windlass in almost identically the same way. It is manifest this would not be a material difference, and for the same reason the push rods of the Patent Office model of June, 1847, are not materially different from the pull rods of the inventors' first model and of the patent.

The only reason push rods were put in the Patent Office model was that the inventors wished to show a bumper brake on the same model. That class of brake always was designed to operate by pushing, and therefore the means of actuating the centre lever when the truck levers it was connected with were pressed inwards by the bumpers, were shown as push rods.

But take the bumper brake out of the model. The necessity for push rods vanishes, and nothing is easier than by slipping the flexible connections out of the shieves and carrying them to the centre lever, to instantly convert the push rods into pull rods.

In Figure 11 this is done.

FIGURE 11.



Does it require invention to do this? Is it not almost a necessary consequence of taking away the bumper brake that anybody would do it? And will this court say that Batchelder and Thompson, who had already done it in their first model in January, 1847, could not do it in the new model filed when the patent was granted, without materially varying from this model in which they had done the full equivalent of it?

It is believed that this part of the case will appear entirely clear, and that in comparing the Patent Office model with the inventors' other models, much confusion will be avoided if the hand-brake portion of it is looked at away from the bumper brake. For that reason, only the hand-brake is shown in Figures 10 and 11.

All that need be said of the fact that in this Patent Office model the connection of the centre lever with the windlasses instead of being made directly by a rod extending from each windlass to it, is made indirectly through the shieves and brake levers of the trucks, is that it is wholly immaterial whether this connection be direct or indirect, so long as it enables the centre lever to be actuated from the windlasses. What possible difference can it make *how* this is done, so long as it *is* done? Because when it is done, since the lever is by rods directly combined with both the truck-brakes, it causes the shoes to be applied to all the wheels simultaneously, whichever windlass is turned. That is the object of the invention, whether in one model or another. All the models—the Patent Office model as well as the others—show the truck-brakes working towards the centre of the car, they show them combined with each other by means of the centre lever, and they show the centre lever moved, and moving both truck-brakes, whenever either windlass is turned. Those are the material things, and if they are found, can it make any difference *how* the turning of the windlass moved the centre lever, or how the moving of that lever actuated the truck-brakes?

CONSTRUCTION OF THE PATENT.

But little need be said on this subject. The claim of the patent is as follows :

"What is claimed by us is to so combine the brakes of the two trucks with the operative windlasses or their equivalents, at both ends of the car, by means of the vibrating lever A′, or its equivalent, or mechanism essentially as specified, as to enable the brakeman, by operating either of the windlasses, to simultaneously apply the brakes of both trucks or bring or force them against their respective wheels, and whether he be at the forward or rear end of the car."

This claim is perfectly plain. As in this case we are dealing only with eight-wheel—that is double-truck—cars, I have in this brief, for the sake of conciseness, used the term *truck-brakes* for the expression in the claim, "brakes of the two trucks." It has already been shown that one of the component parts of Batchelder and Thompson's invention was their truck-brake, formed by modifying the single brake and causing it to work towards the centre of the car; that another was their additional lever arrangement, and that the form of this represented and described in the patent is the central lever A′.

The claim is for a combination, and it is submitted that it is clear from the language of it—taking into view the state of the art and what it has been seen that Batchelder and Thompson actually invented—that the elements of that combination are—

First—The windlasses at both ends of the car.

Second—The truck-brakes as heretofore explained and defined.

Third—The added double lever arrangement as heretofore described—represented in the patent as "the vibrating lever A′, or its equivalent."

Fourth—Connections between the windlasses and this added lever arrangement adapted to actuate the latter when either windlass is turned.

Fifth—Connections between the added lever arrangement and the two truck-brakes adapted to actuate them when the added lever arrangement is moved.

The legal meaning, therefore, of the claim is, that it is for the combination of the windlasses at the ends of the car with the described truck-brakes, by means of the described added lever arrangement and connections between the windlasses and it and between it and the truck-brakes, in such a manner that a brakeman by turning either of the windlasses can apply the brake shoes to all the wheels of the car simultaneously, the whole operating substantially as described.

The claim thus construed is simple and clear, and is commensurate—but no more than commensurate—with what these inventors actually did.

This interpretation of it, tested by what has been shown was the condition of the art when they entered the field, gives to them the precise invention they made. No less, but no more. If it be correct, we shall have but little trouble with the subject next to be considered, which is the last which this Brief will discuss.

INFRINGEMENT.

The brake by the use of which it is claimed that the appellants infringed the patent is known as the "Stevens" brake. It was invented about the year 1851, and was designed by its projector to carry the art of car-braking a step beyond Batchelder and Thompson's mechanism. Whether in actual use it really does this to any appreciable extent, is a question which is abundantly discussed in the proofs taken upon the accounting before the Master in this case. But, at all events, it is unquestionable that over and above what Batchelder and Thompson invented, the Stevens device contains a patentable special combination of parts. It was made the subject of a patent in November, 1851, and the patent and drawing in full will be found at page 76 of the Record. It will not be contended on this argument that that patent is not valid for what Stevens did and what it claims. But it is submitted that it is entirely immaterial whether Stevens devised an improvement in double-acting car brakes, so that, as a result, he made a better brake of that class than was known before. For it is at any rate evident that his brake is double-acting, and it is believed to be capable of demonstration that the means which it employs to simultaneously apply the brakes to all the wheels of the car, from either windlass, contains and uses the combination of Batchelder and Thompson.

The position, therefore, which will be here taken is:

First—That the Stevens brake contains the modified truck-brakes of Batchelder and Thompson, and also the precise equivalent of their added lever system.

Second—That it combines these elements with the windlasses in substantially the same way.

Third—That this combination in it operates in substantially the same way for precisely the same purpose.

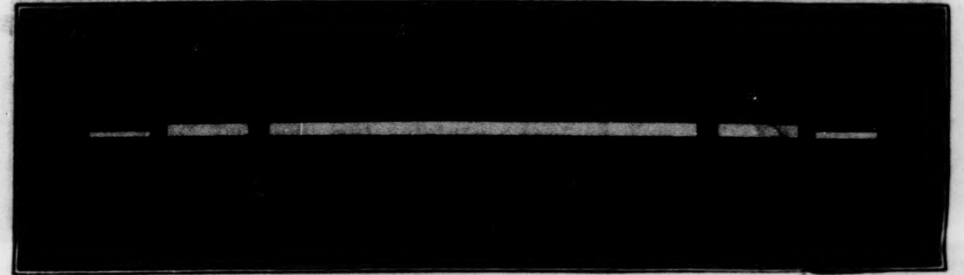
The easiest and shortest way to establish these propositions will be to resort again to Diagrams.

But first it is to be noted that two forms of the Stevens brake are referred to in the Stevens patent. One of these—the one shown, at page 75, in the drawing of that patent—is generally termed the Direct form of the Stevens brake ; the other is termed the Indirect. It is this indirect form of the brake which is represented in the models in the case as being that which was used by the defendants. It is seen in Figure 12.

Figure 12.

The term "direct" merely signifies that the direct Stevens brake is based on the form of truck-brake derived from the direct form of the old single brake, as seen in Figures 1 and 2 at page 6 of this Brief. That, as has been shown, was an early form of the single brake on eight-wheel cars. But in process of time, the evils incident to the inflexible attachment of the truck lever of that brake to the windlass which have been fully described heretofore, came to be recognized as so serious that an attempt was made to ameliorate them somewhat by placing the truck lever at the end of the truck *farthest* from the windlass, so that by lengthening its connection to the latter more freedom might be given to it to yield to the swiveling of the truck on curves. This only partially diminished the difficulty, but still it was some improvement, and it was considerably used until double brakes superseded the single brake. A representation of it applied to an eight-wheel car is given in Figure 13.

Figure 12.



Old Single Brake--Indirect Form.

The form of the Batchelder and Thompson brake shown in the Tanner patent is that which is based on the direct form of truck-brake.

But not long after the introduction of double brakes, they too—the Batchelder and Thompson as well as the Stevens—came to be generally used with the *indirect* truck-brake, that is to say, the truck-brake derived from the above represented indirect single brake. Hence the indirect Stevens brake is that form of it which is based on the indirect truck-brake.

As has been stated, the models show this indirect form as the brake which was used by the defendants.

ANALYSIS OF THE BATCHELDER AND THOMPSON OR TANNER BRAKE IN ITS INDIRECT FORM, TO SHOW THAT THE STEVENS INDIRECT FORM CONTAINS AND USES IT.

First—The Stevens indirect form, that is to say, the defendants' brake, contains and is based on Batchelder and Thompson's truck-brake, and uses it turned round, and working towards, or substantially towards, the centre of the car, as they do.

This will be apparent from the Diagrams.

DIAGRAM FIFTH.

This Diagram represents, in outline, the indirect single brake before being modified in accordance with Batchelder and Thompson's invention to make their truck-brake. It is seen that the levers L and L′ are not yet disconnected from the windlasses, and the trucks are not turned round.

DIAGRAM SIXTH.

We now have Batchelder and Thompson's truck-brake. The windlass connections r and r′ of the single brake are disconnected, the trucks are turned round, and the levers L and L′, and the connections, work towards the centre of the car. To complete the Batchelder and Thompson invention, their added lever system would next be introduced, and when located as shown in the patent, would be placed in the centre of the car, the truck-brake connections r and r′ would be extended out to the proper points on it, and rods would be carried from the windlasses to the extremities of it.

In Diagram Seventh we see the truck-brake of the defendants' mechanism —the indirect Stevens brake. It is apparent that it is precisely the same as the Batchelder and Thompson indirect truck-brake of Diagram Sixth.

DIAGRAM SEVENTH.

Its windlass connections r and r′ are disconnected, *the trucks are turned round*, and the levers L and L′ are *adapted to work towards the centre of the car.*

Here is no "modification of the single brake," which is original with and was first made by Stevens, as is insisted on the other side. It is the *modification of the single brake* which Batchelder and Thompson first made, taken bodily from them—arranged precisely as they arranged it and operating in substantially the same way.

It is specially to be noted that Stevens did not enter the field until about 1851, five years after Batchelder and Thompson had made their invention, and had put into it this very truck-brake mechanism. Their invention therefore was—as to Stevens—a part of the state of the art by which his later claims to originality must be controlled and limited. He needed to use, for the foundation of his brake, such a truck-brake mechanism as is seen in Diagrams Sixth and Seventh. He found it ready to his hand in the prior invention of Batchelder and Thompson and he took it bodily from them. It therefore follows in common sense and in law that his brake is bottomed on theirs and not on the single brake.

Second—The defendants' brake contains, and cannot be used without, Batchelder and Thompson's added lever system, or at all events the substantial equivalent therefor.

It is of course obvious that the Stevens indirect mechanism has levers in it additional to those which formed part of the truck-brakes as he took the latter from Batchelder and Thompson's car. They are the levers marked a and a′ in Figure 12 on page 27 of this Brief, to which the court is asked to turn back. They are not only additional levers, but they are connected with the windlasses by rod and chain connections—one to one windlass and the other to the other—so that they are actuated by the windlasses when either of the latter is turned. They also are the means by which the two truck-brakes are united with each other and made to work in unison, and—since the levers themselves are connected with the windlasses—by which these truck-brakes are combined with the windlasses. They are two "single" levers—the equivalent of Batchelder and Thompson's double lever, and for the same purpose.

It is true they are not put in the same place as the Batchelder and Thompson added lever system is. But can that make any difference? They are in fact the Batchelder and Thompson added double lever, cut in two in the middle at the common fulcrum of its two halves, and, together with the windlass connections of that lever, merely carried back to the trucks and set up there, at a and a′. They are located at a different place in the mechanism, but they are the same things in substance, and they do the same work. The change in their location has, it is true, caused the two truck-brakes to be combined together and when so combined to be connected with the windlasses, by an indirect train of rod and lever mechanism—namely, the rods o and o′, the original levers L and L′ of the truck-brakes, and the windlass rods and chains r and r′, instead of by the direct mechanism in Batchelder and Thompson's invention of the rods G^2 and H^2, and their connections. But since they perform the same work, would it not be trifling with the subject to say that to do indirectly what Batchelder and Thompson do directly, is a substantial difference?

The change in their location is what would be naturally expected from the object which Stevens sought to accomplish. His brake was designed to be simply an improvement upon Batchelder and Thompson's structure, and it aimed to add to the latter the advantage of the well known mechanical principle of the lever, that if equal power is desired to be applied at two points at the same time—as at the two brake-bars of the truck—two equal levers, a, L, and a′, L′, (Figure 12), must be employed between those points. This was his object. He retained Batchelder and Thompson's added levers, but he changed their location and effected his object.

The special combination of parts by which he did this is what he invented, and what his patent claims, and for that it is unquestionably valid.

Third—The mode of combination and of operation in the defendants' brake is the same as in Batchelder and Thompson's invention.

The test of this is to note that by the Stevens added levers a and a′ and their rod connections, the two truck-brakes are united into one system so that the shoes may be applied simultaneously to all the wheels, and the system so combined is connected with both the windlasses, to be actuated indifferently by either of them. It is apparent that this is the method of combination, and the identical mode of operation, of Batchelder and Thompson's brake.

The defendants have called no witness to prove that their brake does not infringe the patent. But the complainant's witnesses, Bond and Cooper, pp. 78, 117, testify that in their judgment it does; and the testimony of the latter, whom the Circuit Judge, in his opinion, calls "a very clear-headed man," is full and strong upon the subject, and the court is respectfully referred to it.

The truth is, the plea that they have not infringed, is an after-thought of the defendants. They abandoned it in the court below until so late that they thereby admitted they had no confidence in it. They took no testimony about it. The first opinion of the Circuit Court, p. 66, explicitly says: "No question has been made in relation to the infringement. It is denied in the answer, but it is not insisted on or pressed in the argument."

Stress is laid upon it in this court, but it is believed that the view taken of it in the brief filed for the appellants is radically erroneous, because it is inconsistent with the state of the art and with the mechanical facts which must govern this case.

It seems clear that these facts compel a decision of this issue for the complainant.

Respectfully submitted,

S. D. COZZENS,

Of Counsel.

SUPREME COURT OF THE UNITED STATES.

OCTOBER TERM, 1878.

THE CHICAGO AND NORTHWESTERN
RAILWAY CO., Appellant,
vs.
THOMAS SAYLES, Appellee.
No. 48.

APPELLEE'S BRIEF
ON
VALIDITY AND ACCOUNTING.

STATEMENT OF THE CASE.

The appellant's "statement of the case" being controverted by the appellee, the latter avails himself of the rule in that regard, by re-stating it.

The original application for the patent, on which this suit is founded, and which was filed in the Patent Office June 26, 1847, was *not* "for a 'train' or 'bumper' brake, operated by the cars crowding on each other when the train slackens its speed."

On the contrary, it appears, upon an inspection of the model and drawings accompanying that application, (the latter of which is reproduced on page 136 of the record, and the former of which is before the court, both in a sworn and in a certified copy,) that the application was for a *combined bumper and hand brake.* It will also appear that the *hand* portions have no necessary connection with the *bumper* parts, and constitute, by themselves, a hand brake, identical in substance and almost identical in form with the brake as patented. It is true, the bumper parts were never used to any great extent; but the *hand* portion proved on trial to be a great and important step in the progress of railroad invention, and has been for many years, and still is, very widely used in the United States.

Moreover, the invention was originally made in October, 1846, in the *exact form* in which it was patented.

In April, 1852, the inventors amended their application for a patent, by omitting therefrom all reference to the bumper portions of the model of June, 1847, and confining their claim to the hand portions thereof, and representing the latter by specifications, drawings, and a model identical in every particular with the hand brake in its original form.

No successful double brake was ever invented or used prior to our invention, though some unsuccessful and abandoned experiments were made in that direction.

This suit was begun in 1861, and passed to an interlocutory decree in 1865. The accounting had progressed a considerable time when, in 1867, the defendant secured an opening of the case, to let in alleged newly-discovered evidence, which, if true, would invalidate the patent for want of novelty. When this issue came to be argued, in 1869, the defendant insisted, *for the first time*, that it did not infringe our patent, even if it was valid. (See opinion of 1865, p. 66, line 19; and opinion of 1871, p. 69, line 43.) This afterthought was a surprise to us, inasmuch as it first appeared in the eighth year of the litigation, and at a time when nothing but a discussion of the alleged want of novelty was in order.

A second interlocutory decree was entered in 1871, and the master's report confirmed by a final decree in 1873. In 1874, that decree was sought to be set aside by the defendant; but the application was refused in 1875, and the final decree amended by the court as to the amount only. Thereupon the defendant appealed to this court, where, after being on the docket three years, the case is now reached for consideration.

It is not proper to say, as the appellant's counsel does, that "If this decree is correct, there is hardly a road that has not infringed this patent"; for the simple reason, that more than *one hundred railroad companies* many years ago purchased licenses to use it, at the low rates the appellee and his assignor were always willing to receive from those disposed to purchase rather than pirate their property.

Neither does counsel hit the mark, when he says "Most of the defendants in these suits have bought and paid for the Hodge and Stevens brakes, on the belief that they are independent inventions, and no infringement." Both those brakes were held to be infringements, in a hotly-contested jury trial, as early as 1854, (p. 25,) and no court or jury has ever, since or before, held the contrary. Infringers do not seem, therefore, to be entitled to much sympathy on account of their "belief," even if it had been generally held by them, of which there is not a word of proof in the record, and which the appellee wishes explicitly to deny.

QUESTIONS IN THE CASE.

1. ALLEGED ABANDONMENT.
2. ALLEGED FRAUD.
3. NOVELTY.
    - A. MILLHOLLAND BRAKE.
    - B. STANLEY-TALSON BRAKE.
    - C. NICHOLS BRAKE.
    - D. JOHN TYLER CAR. (CAMDEN AND AMBOY ROAD.)
4. INFRINGEMENT.
5. ACCOUNTING.
    - A. Is it the infringer's saving, or the patentee's license fee, that is the proper measure of the profits recoverable in this case?
    - B. Was it the single brake, or the Springfield brake, that the master should have adopted as the standard of comparison, when proceeding, as he did, to assess profits under the rule in Mowry *v.* Whitney?
    - C. How much did the defendant save on brakemen's wages, by means of the use of our invention, during the time sued upon?
    - D. How much did it save on wheels?

This brief summarizes the appellee's argument on all of these questions, save that of INFRINGEMENT. That subject, being discussed in the printed and oral arguments of Mr. S. D. Cozzens, needs not to be presented here.

BRIEF OF THE ARGUMENT.

ALLEGED ABANDONMENT.

The statement in this behalf in the respondent's answer is: "That before the issue of said letters-patent, said Thompson and Bachelder had abandoned their said pretended invention to the public."

No abandonment *prior* to the application for the letters-patent can be charged; but it is insisted by the appellant that an abandonment occurred *after* the application, and before the letters-patent were granted.

Such an abandonment was, till 1861, a purely hypothetical one in our law, inasmuch as it had never been contemplated by any statute till then. Indeed, it has never yet been found to exist in any adjudicated case. The courts have, however, recognized the *possibility* of an abandonment of this kind, and have stated the grounds out of which it must arise in order to occur.

"The law does not favor an abandonment, and throws upon the party who seeks to obtain the benefit of a forfeiture, the burden of *proving* it *beyond a reasonable doubt.*"

Nelson, J., in McCormick *v.* Seymour, 2 Blatch., 256 (1851).

"By the application filed in the Patent Office, the inventor makes a full disclosure of his invention, and gives public notice of his claim for a patent. It is *conclusive* evidence that the inventor did not intend to abandon it to the public. The delays *afterward* interposed, either by the *mistakes of the public officers*, or the delays of the courts, where *gross* laches cannot be imputed to the applicant, cannot affect his rights."

Grier, J., in Adams *v.* Jones, 1 Fisher, 530 (1859).

"It is not possible to hold that any use of the invention without the consent of the inventor, while his application for a patent is pending in the Patent Office, can affect the operation of the letters-patent after they are duly granted."

Clifford, J., in Dental Vulcanite Co. *v.* Witherbee, 3 Fisher, 98 (1866).

"The inventors ought not to be held responsible for the errors of others which they could not prevent."

Swayne, J., in Blandy *v.* Griffith, 3 Fisher, 618 (1869).

"Such a defense [as abandonment after application] cannot be sustained, unless the *acts* of the party, invoked for the purpose, are *corroborated* by some *declaration* manifesting such an intention."

Clifford, J., in Jones *v.* Sewell, 6 Fisher, 366 (1873).

Such being the *law* of the matter, the record discloses the following as being the *facts* in this case:

June 26, 1847. Full application was made by the inventors for letters-patent. See File-Wrapper of Application Papers, page 141.

December, 1847. Bachelder and Thompson wrote Heath, their agent, to "stay proceedings," as "they thought they ought to make some alteration in the model they sent to the Patent Office."

Bachelder's deposition, bottom of page 93.

It appears (p. 138) that Heath did accordingly write to the Patent Office December 9, 1847. It is, however, proven by the testimony of Cooper, the Patent Office examiner, (p. 124, q. 3,) that no action was had on the letter, and that the Patent Office paid no attention to that or to the subsequent letters of inquiry (the first of which doubtless contermanded the letter of December 9) which Bachelder says (p. 94, par. 5) Heath wrote at his and Thompson's frequent solicitation. The appellant objects that these last letters are not proved according to the rules of evidence. If It desires to throw them out of the case on that ground, then the letter of December 9, must go with them; for the certificate which covers it is no proof of its genuineness, or that Heath ever actually wrote such a letter at all. It *may*, indeed, have been a forgery, surreptitiously introduced among the papers in the case, years after it purports to have been written, and for the express purpose of helping to defeat our patent.

June 26, 1847, *to October* 9, 1850. It is proven (Cooper's deposition, p. 124, q. 3) that during this entire time the invention and the inventors were entirely ignored by the Patent Office officials.

It is not incumbent upon us to show the *reason* of this apparently strange delay, but we will, nevertheless, point it out. Cooper, the examiner, says (p. 124, q. 2) that "at all times, applications for patents are liable to be overlooked and delayed, until inquired for by the applicants or their agents."

It appears from the File-Wrapper and its contents that Heath filed no power of attorney, or other evidence of authority to act as agent for the inventors, until October 4, 1850; so that the Patent Office had no knowledge whatever that he had power to do anything for them, and therefore ignored all his letters. Not being urgently reminded of the existence of the application by any duly authorized party, the Patent Office ignored it, while giving attention to later applications, which were "engineered" through by persistent and skillful agents.

The *law*, however, does not contemplate it to be necessary for applicants to be continually "button-holing" the Patent Office officials, and urging them to do their duty. Heath's letters urging the Office to proceed were natural enough, but they were wholly unnecessary in the eye of the law.

On the contrary, the application being duly placed on file in the Patent Office, the *next* duty devolved on its officers, which duty was to examine the application, and either grant the letters-patent or notify the applicants why they could not do so; and if their inability arose out of defective or insufficient specifications, also to give them such information and references as might be useful in judging of the propriety of altering the same.

Patent Act of 1836, sec. 7.

Neither of these duties, however, had been performed before October, 1850.

See File-Wrapper, pp. 141, 142.

Early in that month Heath wrote again to the Office, fortifying himself for the first time with evidence of his authority to act, in the shape of a formal assignment from the inventors. (p. 138.) Thus stimulated, the Patent Office for the *first time* paid any attention whatever to the case, by returning the papers to Heath's agent, Eddy.

October, 1850, *to October*, 1851. During this period Mr. Eddy reviewed the papers and returned them to the Office, and after waiting several months for the latter to act, and again urgently writing it for its decision, succeeded, in October, 1851, in receiving a letter, in which the officers of the Patent Office informed the inventors for the *first time* that the drawings and specifications were insufficient; (p. 139;) but even *then* they gave no information as to how they might be *corrected*, as it was their duty under the statute to have done.

July 6, 1852. In less than nine months after the Patent Office did even a *part* of its preliminary duty in regard to the case, amended specifications and drawings, and a model to correspond exactly therewith, were furnished by Mr. Eddy, and filed in the Office; and the letters-patent were obtained by him for Mr. Tanner, who, in April, 1852, had purchased the invention from Bachelder and Thompson.

The truth, therefore, is, that the inventors applied for their patent in June, 1847, and, without any fault on *their* part, were unable to get the Patent Office to examine the case till October, 1851, and within nine months after they received the first information that the application papers were insufficient, proper amendments thereto were made, and the letters-patent obtained.

It is not true that Heath became sole owner of the invention in April, 1847, as the counsel for the appellant asserts. The real relations of Bachelder and Thompson with Heath, Bellowes, Eddy, and Tanner were as follows: Bachelder and Thompson, being poor at the time of their invention, and therefore unable to pay a patent solicitor in *money*, (Bellowes' deposition, p. 89, line 23, and Bachelder's, p. 95, line 8,) *agreed* to give Heath *one-third* of the patent for obtaining it. (p. 94, line 52.) Late in 1847, Bellowes was admitted, by joint agreement of Bachelder and Thompson and Heath, *which agreement* provided that Heath and Bellowes were each to have one-fourth of the *proceeds* of the patent; (p. 95, line 10;)

the consideration for this agreement being, that Heath was to "do the business in regard to obtaining the patent," (Bellowes deposition, p. 89, line 21,) and Bellowes was to be at the expense of trying the brake on the railroads. (p. 95, line 14.)

After the six months from date of the application, at the end of which time Bachelder and Thompson had been informed that they might expect to receive the letters-patent, (p. 94, line 30,) they frequently—*i. e.*, after December 27, 1847—applied to Heath for an explanation of their disappointment in not receiving it. (p. 94, line 32.) He replied, assuring them that he was doing all he could to get the letters-patent, by writing the Patent Office, which is the only method of "button-holing" that can be practiced by non-resident solicitors. This went on for a considerable time, but at last Bachelder and Thompson grew restless under the delay, and plainly told Heath that if he could not secure the patent they would rescind their agreement with him, and secure the services of somebody who could. (p. 94, line 6 from the bottom.) Heath, thinking he had a good thing, did not want to lose it, and therefore endeavored to placate them.

Thereupon they insisted that if he wanted to continue his relations to the invention, he must employ Mr. Eddy, a well-known patent solicitor. Heath objected on two grounds: 1. He was on ill terms with Eddy (p. 94, line 16 from bottom); 2. Eddy's charges were high. (p. 95, line 4.) Their urgency, however, finally prevailed, and Heath finally consented to employ Eddy "some." (p. 95, line 9.)

It seems that even after Heath employed Eddy "some," in order to placate the urgent inventors, the two former gentlemen did not pull well together, for Eddy made no change in the application papers, but returned them to the Patent Office in July, 1851, for consideration there. Bachelder and Thompson were now getting very impatient, and *themselves* soon after went to Eddy, to see if something could not be done to get the officials in the Patent Office to recognize the existence of the application which had been filed there more than four years before, and about which, during the last three years and a half, they had written, through Heath, for information, but *never* could get any reply. (p. 139, par. 3.)

Accordingly, Eddy wrote the letter of September 10, 1851, at the close of which occurs this language,—the language of two long-neglected and impatient inventors:

"They now *respectfully* request that their application may be *examined*, and the result reported to me."

That is the very thing the Patent Office, according to the law, ought to have done, *without* all this "punching up." At last, however, as we have seen, that Patent Office did *one-half its duty* in October, 1851; but instead of conforming to the law as to the other half, they departed from it, by saying, that because the specifications and drawings were insufficient, "the Office, from what it can learn of the case, cannot encourage you, however, to press the application further."

Notwithstanding this very discouraging letter, Bachelder and Thompson were still determined to pursue their application. (p. 97, q. 16.)

We ask the court to bear in mind that these inventors put forth all this diligence before they ever heard or knew of Henry Tanner.

Henry Tanner was the owner of the *Turner* patent for a double brake which had been invented by a clergyman of Buffalo, New York, named Turner, in 1848, and which was so different from the Bachelder and Thompson invention, that if it had been useful, it was doubtless patentable, notwithstanding the latter. It had a center lever operating from either end of the car; but instead of *one* lever in each truck, it had *eight*, the idea being to have a lever on each side of all the four wheels. Henry Tanner, however, soon after he bought the patent of Turner, in 1849, was genius enough to see that the eight levers were wholly impracticable; and he accordingly had a model made, for the purpose of exhibiting the valuable part of the invention, with the center lever and one lever in each truck, and hitting upon the exact form of brake that had been invented by Bachelder and Thompson in 1846. (p. 539, re-direct q. 2, 3.)

Some time in 1851 Tanner went to Hartford, Connecticut, with this model, for the purpose of introducing it there, (p. 540, x-q. 3,) and found to his surprise that Nichols, the master mechanic on the railroad, had already made the same thing, (p. 541, x-q. 12,) having done so, as we shall hereafter see, in 1848, about the time Turner made *his* invention.

In the winter of 1851–52 Tanner sought to surrender and reissue the Turner patent, so as to confine it to the combination experience had taught him was the practicable one; but though Turner was entitled to a patent for his original combination, the reissue could not be granted as desired, simply because Bachelder and Thompson had invented precisely the same thing, as the Patent Office had abundant reason to know from the frequency with which its attention had been called to it by Heath and Eddy. It accordingly so informed Tanner.

Tanner had been the first man in the United States to travel extensively among railroads and introduce double brakes. He saw at once that his occupation would be gone the moment Bachelder and Thompson obtained letters-patent, unless he could obtain an interest therein. Accordingly, he visited them, and secured from them the assignment of the *legal title*, printed on page 70 of the record. The one hundred dollars mentioned therein was a merely nominal consideration, which more properly would have been written *one* dollar. The *real* consideration is proven by Bachelder (p. 97) to have been as follows:

> "Int. 18. What consideration did Mr. Tanner offer for your application, and what consideration did you accept?
>
> "A. He offered to pay us one-half he collected, after deducting twenty-five per cent. from the whole sum collected for collecting, and we accepted that offer. For all expenses, and lawsuits also, he was to be reimbursed from the general fund."

This history, deduced wholly from the record, shows conclusively that it cannot be claimed by the appellant that the inventors were themselves guilty of any neglect; but it is claimed that their *agents*, Heath and Eddy, were lacking in diligence, and that "The neglect of their agents is the same as their own." On this point, however, the appellant labors under the disadvantage of disagreeing with Mr. Justice Swayne, who held, in Birdsell *v.* McDonald, 6 Pat. Off. Gaz., 682, (1874,) that the inventor is not chargeable with the neglect of his agent in such cases. What Heath *really* lacked, however, was *not* diligence, but *experience* and *skill.*

That it is the policy of the law to give inventors ample time in which to perfect their application, is exemplified by the Patent Act of March 2, 1861, which provided, in effect, that abandonment of an application shall be held to have occurred only when the specifications and drawings shall not be filed within two years after the petition, or when the applicant fails to prosecute his case within two years after *action by the Office*, of which he has been *notified;* and not even *then*, if the delay is shown, to the satisfaction of *Commissioner*, to have been unavoidable.

Moreover. Bachelder and Thompson showed conclusively that they never intended to abandon their application, inasmuch as, notwithstanding their poverty, they did not apply for the return to them of the portion of the application fee to which, in the event of such abandonment, they would, under section 7 of the Act of 1836, have been entitled.

This court held, in the case of Smith v. The Goodyear Dental Vulcanite Company, 93 U. S., 500, (1876,) that Dr. Cummings did not abandon *his* invention, though he was unable for *eight years* to prosecute it further, after the unfavorable action of the Patent Office upon it in 1856.

In the case at bar, it was only a little over *eight months* after the *first* action of the Office that the application was not only prosecuted, but prosecuted to a successful issue. Under these circumstances, this court will doubtless coincide in the opinion his honor Judge Drummond gave in the case, which was, that "The whole testimony shows that they [the inventors] had *not* abandoned what they considered to be an improvement, to which they had a right under the law. Certainly they cannot be held responsible for delays in the Patent Office, and the law, by its terms, provides for the perfection of imperfect and insufficient specifications even after the patent issues."

See opinion of 1865, p. 63, last paragraph.

ALLEGED FRAUD.

Under this head, the answer of the appellant states "That said letters-patent were obtained wrongfully and fraudulently by the said Tanner." And it is claimed by the counsel, in his brief, that the fraud consisted in Tanner's obtaining the letters-patent in 1852 for a different invention from the one embodied in the model, specification, and drawings accompanying the application of June, 1847.

This allegation would be sufficiently met by citing the cases in which this court has held that a patent of the United States can be attacked on account of fraud in its issue, only by means of a direct proceeding to repeal it, and never collaterally. Some of those cases are Rubber Company *v.* Goodyear, 9 Wall., 798 (1869); Eureka Company *v.* Bailey Company, 11 Wall., 492 (1870); Seymour *v.* Osborne, 11 Wall., 543 (1870); Mowry *v.* Whitney, 14 Wall., 439 (1872).

In the last of these cases, it was also held that a proper direct proceeding of the kind will be as effectual to declare an expired patent null *ab initio* as to repeal a patent still in force, and even if this were not so, the appellant could not complain; for the answer in this case, setting up the alleged fraud, was filed more than eleven years before the patent as extended expired, and when more than four years of its *first* term still remained in which to secure its repeal, if any ground existed therefor.

Fraud will not be *presumed*, but must be proved; and all the more so, because if it occurred the Patent Office participated therein, inasmuch as Tanner could not have *obtained* a patent based on an old application for a different invention without the Patent Office having *granted* it, and, equally with the receiver, being guilty of the cheat.

The appellant, indeed, never had faith enough in its own charge of fraud to take any testimony to prove it.

The appellee, however, did introduce evidence to *negative* the charge, by proving the substantial identity of the invention patented, with the *hand* part of that upon which the application of June, 1847, was based, consisting of:

First. That of an eminent expert, whom his honor Judge Drummond complimented very highly in his opinion of 1865, (p. 66, line 4,) but of whom the counsel for the appellant speaks as "one Cooper, who is *made* to swear." This gentleman, in judging of whose qualifications this court will be governed, on the one hand, by the inherent strength and clearness of his testimony, together with Judge Drummond's opinion, or, on the other, by the poor opinion of Mr. Payson, is fully questioned and cross-questioned on this subject. He says (p. 106, a. 6): "The invention claimed in the Tanner Patent referred to, is embodied in the Patent Office model originally deposited with the Bachelder and Thompson application. It is also represented in the drawings, and described and distinctly claimed in the original application. The specifications evidently were not drawn by an adept; neither were the drawings made by an artist; but there is sufficient to show that the invention then claimed was the same as that now claimed in the patent, notwithstanding the dissimilarity of language in the two documents. * * * * *In the drawings, we find a particular description of all the parts which go to make up this hand operation of the brakes which is claimed in the* Tanner Patent. The cross lever in the center of the car is lettered D. The connections between this lever and the brake levers are lettered A. * * * * In the specification, I find as follows: The letters *A*, C, *D*, H, and I are the parts which we claim as our improvements. It is customary to put the claim at the end of the specification; but it is very common, with persons not acquainted with the method of soliciting patents in this country, to put their claims anywhere in the body of the specification. This is not allowed in our Patent Office, but it is in England. There is another claim, at the close of the specification, the purport of which is rather obscure, but I notice, that while the parts referring to the hand operations are lettered and described, those parts which refer to the application of the brakes by the backing of the engine are neither lettered nor particularly described, but are simply referred to. It would not seem, therefore, that even the claim at the end of the specification could be intended to refer to the application of the brakes by the bumper."

And on cross-examination Mr. Cooper says (p. 109, x-q. 3):

"So far as concerns the operation of the brake, I have no doubt that it could be so applied [*i. e.*, so applied and operated as to be an acceptable brake to railroad managers]. I might suggest mere mechanical changes of arrangement; but there is a wide difference between such changes and the changes which involve invention and the introduction of new principles of action. I should prefer to operate the center lever by pulling instead of pushing it; but that is a mere mechanical change, which every mechanic understands."

Second. A comparison of the Patent Office model of 1847 with the one of 1852, which latter is an exact representation of the brake as patented, will show the court that there is no substantial difference between the two, and that the *apparent* difference arises almost wholly out of the fact that the model of 1847 contained, in addition to the *hand* brake, a "bumper" arrangement, having no necessary connection therewith, and which has nothing to do with the case at bar.

In making such comparison, it is proper, therefore, to ignore, in the model of 1847, the butters and the rod H—the butters being intended to collide with the two truck levers, and the rod H being designed to liberate the truck levers from the butters, when it was desired to back the train.

The "bumper" portion being thus eliminated, the court will see that the model of 1847 is identical with that of 1852, save that in the former each windlass is connected by means of a chain to one part of the mechanism, viz., the top of one truck lever; while in the other it is connected by means of a chain and tensile rod to *another* point, viz., to one end of the center lever; the direction of the movement of every part being the same in both models. There are also two other very slight formal differences, to wit: In the model of 1852 the truck levers are placed nearest the inner brake bar in each truck, while in that of 1847 they are placed nearest the outer brake bar; and in the model of 1847 the rods connect the center lever to the truck levers at the ends of the former, while in that of 1852 they are connected to it a little nearer its fulcrum. These differences are, however, the merest matters of form. Every identical part of the combination in the model of 1852 is in the model of 1847, save that in one case chains are used to transmit tensile strain, and in the other, chains and rods are united for that purpose.

Appellant's Argument Answered.

The learned counsel says:

First. "It [the center lever in the model of 1847] does not receive the power from the windlass and transmit it to the brake levers, but receives it from one lever and transmits it to another."

He himself elsewhere shows that this is of no importance; for he construes our claim on page 67 of his brief, and prints his construction in capital letters. His formula there is, "Combining the two sets of *brakes and windlasses*, by means of the vibrating lever A^1, or its equivalant, so as to apply all the brakes at once from either end [of the car]." On page 68, line 6, he intimates we *might* perhaps have had a broader claim; and in line 16 calls this claim "precise and definite."

A glance at the two models will show that the center lever combines the "two sets of brakes and windlasses" just as truly in one as in the other. The counsel himself says, at the bottom of page 16 of his brief, that the claim printed on page 542 of the record, and which he says, on page 17, line 4 of his brief, was adopted in the Tanner patent with "some slight verbal changes," is in terms fitted equally well to what he calls the Bachelder and Thompson brake, (the model of June, 1847,) and the Tanner brake. The counsel, therefore, has himself killed his first, and indeed his whole attack on the identity of the two models, by saying that a claim which he characterizes, at line 16 of page 68 of his argument, as "precise and definite," "*is in terms fitted equally well to either.*" A precise and definite claim could hardly be *in terms* fitted *equally well* to two machines substantially different from each other, as the learned counsel insists these two models are, but which we have shown they are not.

The learned counsel says:

Second. "One of the rods of the model of June, 1847, is a pull and the other a push rod alternately; and the consequence is, both have to be made very thick and heavy to stand the thrust."

Even if this consequence were true, one naturally inquires, "What of it?" Cooper, however, shows (p. 110, q. 10) that only half the power exerted by the brakeman is transmitted through the rod, and (p. 109, q. 7) that it is an entire mistake to suppose that a very strong bar would be required for the purpose.

The learned counsel says:

Third. "This center lever [that in the model of June, 1847] does not increase the power of the windlass." When hard pushed to make out another part of his case, he says (p. 23, line 17): "But no one would think of claiming that it was any less the Tanner lever on that account,"—thus again assassinating on one page the argument he strenuously makes on another.

The learned counsel astonishes us by saying, (p. 13, line 21,) "We have thus four connecting rods [in the Tanner] instead of two, [in the model of 1847,] and no two of them answering to the two connecting rods in the latter." We ask the court to notice that the two rods connecting the truck levers to the center lever in the model of 1847 do answer exactly to those that connect the same parts in the model of 1852, except that the latter join the center lever somewhat nearer its fulcrum, which, as we have seen, the counsel himself says is immaterial.

The learned counsel says in another place, (p. 14,) that the language used by the penner of the original specification, to include the windlasses and the chains that connect them to the brake system, refers to the only part of the whole contrivance that gives any color to the claim that the brake was ever intended for a hand brake, and italicizes the dreadful remark, that "It is not claimed as any part of the improvement."

The *reason* they were not so claimed, was doubtless because they were not *new*, being found in the same place in the single brake. The draughtsman of the specification was evidently under the pardonable though erroneous impression, that, when drawing a claim to cover a combination of old and new ingredients, he could claim *only* the new ingredients as used to combine the old, and could not claim *all* the ingredients *as combined.*

The learned counsel also says, (p. 14, line 6,) "Where the specification says that the brake may be applied by hand at pleasure without reversing the engine, it does not mean that it is to be used as a hand brake, but simply that this is another way of applying the bumper brake without reversing the engine."

To this complexion does he come at last!

A statement that a brake may be applied by hand at pleasure, don't mean that it is a hand brake! !

Mark his reasons: "The hand brake is applied on the foremost car, *thus slackening its pace*, and the other cars crowd on it and on each other, and thus the bumper brake is applied throughout the whole train." Did it not have to operate as a *hand brake only*, in order to slacken the pace of the foremost car? Moreover, suppose there is only one car on the train, as sometimes happens: then, if the engine is not reversed the bumper would not act at all, and the application of the brake "by hand at pleasure" would be the only *possible* application of the brake.

Against these arguments thus founded, interspersed as they are by worn-out and baseless innuendoes, and by unsworn statements quite foreign to the record, we interpose the opinion of his honor Judge Drummond, which may be found on page 63, beginning in line 12 from the bottom. His honor says: "A question connected with this, is whether, when the application was made, in June, 1847, there was substantially the improvement, the right to which was sought to be given to them by letters-patent in 1852; and I think there was. It is true, there was a change in the specification as perfected and as originally filed, *more* having been claimed in the original specifications. Still, I think it is *clear* that they claimed, in their original specifications, substantially the method of combining the brakes in the manner in which they set the claim forth in the last specifications upon which the patent issued."

The learned counsel for the appellant endeavors, in the space between IV on page 18 and II on page 22 of his argument, to show that the Scriptures are wrong in saying, "The [uncontradicted] testimony of two witnesses is true." Bachelder (p. 93) and Bellowes (p. 89) testified that the models before the court—known as the Bachelder model and the Fitchburg model—accurately represented the brake as invented in 1846, and as applied to a car on the Fitchburg Road in 1847, respectively.

There is not a particle of evidence in the record to contradict them in that regard; but the appellant complains because we did not corroborate them by four other people, namely: Thompson, who has been dead many years, having lost his life while serving in the army of the country that sought to reward him as an inventor; Heath, who for many years has lived in California, and who could have been reached at the time this testimony was taken only by a long overland or ocean journey; and Eddy and Tanner, who could have no possible knowledge on the subject except hearsay.

NOVELTY.

THE MILLHOLLAND BRAKE.

It is urged, by the appellant, that our patent is void for want of novelty, by reason of the use in Maryland, by one James Millholland, of the same machine, on one car, a year or more before our invention was made.

A model representing that brake is before the court; and we admit that one such drum brake was made, and attempted to be used, prior to our invention.

We deny, however, that it was the same as the Tanner, and insist that the attempted use was not a successful one, and that its entire history constitutes nothing but one of those *unsuccessful experiments abandoned*, with which the path of invention is always strewed. There are in the case only three short depositions pertaining to the matter on behalf of the appellant, and eight on behalf of our patent.

There is discord between some of those depositions, with regard to the *length* of time Millholland's brake was on the car to which it was attached; but, taking the entire testimony together, the facts are clearly shown to be as follows, concerning

Its History.

First. In April, 1845, Mr. Millholland first put his brake on one passenger car of the Baltimore and Susquehanna Railroad.

Mr. Millholland says "he thinks" it was put on "about" 1843; and Smith says he is not positive, but thinks the time was about 1843; while Leahy, the other one of the appellant's witnesses, says "the impression on his mind is that it was put on in 1843." Neither of the three, however, adduces any circumstances to corroborate his recollection.

On the other hand, Woods, one of the appellee's witnesses, says (p. 83) that it was applied in April, 1845, soon after he ceased to be a fireman and took charge of a stationary engine, located about 100 yards from the shop where he saw the drum brake being put on. He says that he took charge of this stationary engine April 1, 1845; and Hollins, who kept the pay-rolls, corroborates him in this particular.

Francis also says (p. 79) that he was a brakeman on the passenger train for the nine months prior to April, 1845, when he was changed to the freight train, and that the drum brake was not put on till after he went on the freight train. Hollins shows that this event took place early in April, 1845.

Yakel also says (p. 85) that when he began to work on the road as brake man on the passenger train, in April, 1845, (which, he says, was his first employment on any railroad,) the single brake was used on all the passenger and baggage cars, but that the drum brake was put on one passenger car a short time thereafter; and Hollins shows (p. 84) that Yakel began work April 9, 1845.

Elder says (p. 80) that he painted the drum brake when it was newly put on the car, and before it was used, and that he did so shortly after he succeeded Mr. Benson as foreman of the paint shop, which event, Hollins shows from the pay-rolls, took place April 11, 1845.

Denmead, who was foreman of machinery under Millholland, also says (p. 80) that the drum brake was put on in 1845, and that he remembers that Yakel was a brakeman on the train, on one of the cars of which the drum brake was used.

Our *five* witnesses, all of whom agree, and all of whom are corroborated by circumstances and by dates which were recorded in the pay-rolls of the company, must of course outweigh on this point the *three* witnesses of the appellant, none of whom either speak positively or are corroborated in any way. Accordingly, Judge Drummond, in his opinion of 1865, says that he thinks it appears satisfactorily that Millholland's brake was not used until 1845.

Second. In June, 1845, Mr. Millholland ordered his brake taken off the car to which he had applied it less than two months before, putting back the single treadle brake in its place, and never attempting to do anything more with the drum brake.

Wood says (p. 83) that the car with the drum brake was taken into the shop about the 1st of June, 1845, and the drum brake was taken off; and when he saw the car come out again it had on the old single treadle brake. Denmead says (p. 80) that the car on which the drum brake was put was repaired some short time afterward, and the drum brake taken off by Millholland's orders, and the single treadle brake put on in its place, and the drum brake not put on the car after it was repaired.

Yakel says also (p. 86) that he recollects distinctly that the drum brake was not put on the car after she was rebuilt.

Smith, the appellant's own witness, says (p. 164) the car was taken into the shop to be rebuilt in June, 1845, and that it is his impression the drum brake was removed from the car at that time.

Third. The drum brake was proved, during the short time it was tried on the car, to be an entire failure.

Yakel says (p. 85) he was the only brakeman employed on the train in which the drum-brake car ran, except the baggageman, who merely attended to the brake on his own car; that the car with the drum brake ran for a short time, about two days out of three, only 30 miles out of Baltimore in the morning and back again in the afternoon; that the drum brake worked very badly as compared to the single treadle brake; that he could not stop the train with the drum brake, though in trying to do so he several times applied it so hard as to break the chains; that he complained of these facts to Millholland and Denmead, and that consequently the car was left in the shed, unused for a time and then rebuilt, and the drum brake taken off and the single treadle brake put on in its place.

Woods says (p. 83) he recollects seeing the drum-brake car standing on the track in front of the shop a good share of the time; that it was not used generally, and that the engineer and brakeman complained that the drum brake was inefficient, and did not answer the purpose for which it was intended.

Denmead also (p. 81) fully corroborates Yakel, in saying that there were frequent complaints about the brake's inefficiency made to Millholland, Smith, and himself; and adds, that the trial of the drum brake proved a failure, and was abandoned.

Neither Francis, Elder, nor Hollins was in a position to know how well or otherwise the drum brake actually worked, and therefore say nothing on that point.

Fisher, the engineer, (pp. 91, 92,) however, fully corroborates Yakel, the brakeman, as to the worthlessness of the drum brake; and adds, that the reason the car was generally left at Parkton, 30 miles from Baltimore, instead of being hauled the 70 miles the train ran, was because they did not consider the brake safe to go over the summit with.

Millholland is the only witness who says he never heard any complaint about the working of the drum brake; but in view of the fact that he ordered it taken off after a short trial, and that Yakel swears he did make complaint to Millholland, and that Denmead says *he* knows the brakeman (Yakel) complained to Millholland about its inefficiency, Mr. Millholland's opinion, that he never heard any complaint, is thoroughly negatived.

Its Character.

It is a strange mistake of the law to say, as the counsel for the appellant, does, that "Millholland might certainly have obtained a patent for his brake."

He could *not* have obtained a patent, or if he could it would not have been *valid*, because his machine was not "useful" in the sense in which that word is used in the Constitution and the statutes, and as construed by the courts.

So far from being what the courts say a machine *must* be, to be useful in the sense of the Patent Law,—*i. e.*, "capable of successful operation,"—the short attempted use of the Millholland brake showed that it was wholly *incapable* of such operation. Millholland himself was of that opinion; for he abandoned it, and two years afterward told Leahy (p. 167, line 26) to keep a certain car in the shop till he could devise a double-acting brake,—thus showing conclusively that he thought the drum brake incapable of successful operation.

Our statement, that the Millholland brake was not even theoretically like the Tanner, will be seen to be true the moment it is remembered that, according to the learned counsel's own construction, (p. 67 of his brief,) ours is a patent for "Combining *the two sets of brakes* and *windlasses* by means of *the vibrating lever* A^1, or its equivalent, so as to apply all the brakes from either end [of the car]." Now, what does the counsel mean by "two sets of brakes"?

He himself defines the expression (p. 77, line 8 of his brief) to mean "the old single brake"; so that according to *the counsel's own showing* ours is a patent for a *combination* of three classes of ingredients, viz.: 1. The old single brakes; 2. The windlasses; 3. The vibrating lever A^1, or its equivalent.

He admits, what we will shortly explain, viz., that Millholland did not have the first of those classes of ingredients at all,—but had instead thereof a peculiar system of his own in the trucks, wholly unlike the "old single brake," and indeed unlike anything that anybody except Millholland ever thought of introducing into a car brake.

We say that the truck system of Millholland is not the equivalent of the truck system of the single brake, which is the first ingredient of *our* combination, because it is wholly lacking in the self-adjustability of the latter. If one pair of brake shoes in the latter become more worn than the other, the system at once adjusts itself to the changed condition,--a thing the Millholland truck system is wholly incapable of doing; and, what is still more important, the play in the journals always results in the rear pair of wheels of each truck falling back *from* the pivot of the truck lever, and the forward pair falling back *toward* that pivot, so that when the shoes are brought hard in contact with the rear pair they are at least one-eighth of an inch away from the forward pair, and therefore are as useless as though they were not on the car at all. This condition of affairs is reversed when the direction in which the car is run is reversed, because the wheels that before were the forward ones now become the rear ones in each truck. The self-adjustability of our truck system wholly obviates the evils that in the Millholland truck system constantly arise from either or both of these causes.

It is true, that Millholland *might* have combined the first element of our combination (viz., the old single brakes) with the *second* element, (viz., the windlass,) by means of his drum, if he had been gifted with sufficient inventive power. He, however, did nothing of the kind. The learned counsel, however, says "we" (he?) can do it now! In other words, he says, "It is true the Millholland brake did not anticipate the Tanner patent, which is a patent for a combination; but if the court will give me time I will get up one that will."

Furthermore, it is an entire mistake to assume, as the counsel for the appellant does, that the drum of Millholland performs all the functions, and is therefore the equivalent of our lever A^1. While speaking of and explaining away to *his* satisfaction certain differences that he apprehends we *might* point out between them, he says nothing whatever of a very substantial difference we *do* wish to call attention to, and which would be fatal to the practical utility of a brake even like the one in the learned counsel's chart, which he denominates "The Millholland Brake Slightly [?] Modified," and which figure 12 represents a purely imaginary structure, and one never before heard of in this case.

The fault we now speak of, is the constant liability of one or the other of the chains to "kink" or to "spiral" when the other chain does not, in either of which events all the power applied by the brakeman would pass to the truck connected by the kinking or spiraling chain, and, when *there*, pass to the rear brake bar in that truck, on account of the peculiar nature of the system in the truck, which we have explained.

That this kinking and spiraling takes place on a shaft, (a drum is only a large shaft,) and that it must produce the effect we assign to it, is very obvious, and, moreover, is sworn to by a number of witnesses, none of whom are contradicted. (See Hitchcock, p. 1080, x-q. 29–33.)

The counsel for the appellant says, (p. 71 of his brief, line 25,) "In the Tanner brake, the power is first communicated from the windlass, by means of its rod and chain, to one end of the lever A^1. There the power is divided, [by the lever,] *part* being sent back to the brake lever in the nearest truck, and the *rest* sent forward to the brake lever in the farther truck." Now, whenever one of the chains that connect the Millholland drum with the brake levers happens either to kink or spiral, this function, which the learned counsel says the Tanner center lever performs, cannot be performed by the drum. On the contrary, in all such cases, which are liable to happen at any time, the power transmitted from the windless to the drum is not and can not be divided between the two trucks at all. The drum is, therefore, *not* the equivalent of the center lever, because, though it may *happen* sometimes to perform the functions of the latter, it cannot be *relied* upon to do so at *any particular time.*

The conclusion of the whole matter, therefore, is, that the learned counsel asks this court to invalidate our patent, (which he says in effect covers a combination of three classes of ingredients,) on the ground that James Millholland *failed* to accomplish the same *result* we *did* accomplish by *another* combination of three classes of ingredients, of which only one class (the cranks handled by the brakemen) were the equivalents of the corresponding class (the windlasses) in ours. When arguing *validity*, he sets up this prior machine, because it was designed to accomplish our *result*, no matter how different the *means*, or how useless the machine. When discussing *infringement*, he substantially ignores the *result*, and then becomes a stickler for the necessity of finding identity of *means*.

We have thus far explained the *history* and the *character* of the Millholland brake. We will close the subject by quoting

Its Law.

"The settled rule of law is, that whoever first perfects a machine is entitled to a patent, and is the real inventor, although others may have previously had the idea and made some experiments toward putting it in practice. He is the inventor, and is entitled to the patent, who first brought the machine to perfection, *and made it capable of useful operation.*"

Agawam Co. *v.* Jordan, 7 Wall., 583 (1868).

"He is the first inventor, and entitled to a patent, who, being an original discoverer, has first perfected and adapted the invention to actual use."

Whitely *v.* Swayne, 7 Wall., 685 (1868).

"The invention relied upon as a defense must have been complete, and capable of producing the result to be accomplished; and this must be *shown* by the defendant. The burden of proof rests upon him, and every reasonable doubt should be resolved against him. If the thing were embryotic or inchoate; if it rested on speculation or experiment; if the process pursued for its development had failed to reach the point of consummation, it cannot avail to defeat a patent founded upon an invention which was completed, while in the other case there was only progress, however near that progress may have approximated to the end in view. If the question relates to a machine, the conception must have been clothed in substantial forms which demonstrate at once its *practical* efficiency and utility. Until the work *is done*, the inventor has given nothing to the public."

Coffin *v.* Ogden, 18 Wall., 124 (1873).

THE STANLEY-TALSON BRAKE

Under this heading, the appellant claims that our patent is void for want of novelty, by reason of a brake which the counsel says was applied on the New Jersey Railroad in 1842, and which he says was used only a short time and then abandoned. The counsel says it had *one* of the three classes of ingredients in our combination, viz., the center lever, but that the arrangement in the trucks seems to have been *somewhat* different. As to the nature and extent of that difference he gives the court no light. In fact, not a word further is said about the *facts* of the case, except to quote some language which the counsel *asserts* one of the witnesses *swore* Talson had at some period *told* him, touching the reason Talson *assigned* for the brake *not operating successfully*; and some other language which counsel *asserts* another witness used in giving his *views* on the same subject. Upon which of the 1174 pages of the record this language is to be found, the counsel gives us no hint, and a more diligent search by the writer than the importance of the matter required has failed to disclose. On the contrary, the erudite counsel plunges at once into the law books, determined to draw from thence *jurisprudence* enough to defeat our patent, for want of novelty, *without* any facts.

It seems, therefore, that if the matter is to be understood, the counsel for the appellee will have to explain it, which he will how essay to do.

Joseph F. Talson was superintendent of the car department of the New Jersey Railroad from 1836 to 1849. (p. 303, q. 2.) In 1853, when the action at law of Henry Tanner *v.* The Hudson River Railroad Co. for the infringement of our patent was about to be tried, Mr. George Gifford, Thomas M. North, John H. Reynolds, and Wm. Wheeler Hubbell, of counsel for the defendant, (Gifford's deposition, p. 521, q. 5; North's deposition, p. 494, q. 5,) were engaged in ransacking the United States, and especially the State of New Jersey, for evidence with which to defeat the patent for want of novelty. (p. 545, q. 3; p. 522, q. 12; p. 543, q. 5.) Among the people they discovered was Joseph F. Talson, and him they carefully interrogated, with the conclusion that he knew of no sound defense to the patent; (Gifford's deposition, p. 523, q. 15;) and they therefore advised the defendant to purchase a license, which it did.

The next year, however, (1854,) Mr. Gifford was retained to defend the New York and Erie Railroad Co. against our patent, in a case that went to trial in October. Here he put Mr. Talson on the stand for what he was worth, and Samuel Blatchford—now Circuit Judge, but then counsel for the patent—took and preserved copious notes of his testimony.

The italicized statement of the appellant's counsel, (p. 61, line 27,) that some of these four lawyers for the defendant—*i. e.*, Gifford, Reynolds, North or Hubbell —"are now retained by the patentees," is one that the honorable counsel, in justice to those gentlemen, ought never to have made. (See Gifford's deposition, p. 524, re-direct q. 1.) "Were you ever retained in favor of the Tanner patent by Mr. Sayles, the complainant in this case?" A. "I was not."

It is believed that the honorable gentleman knows very well that Mr. Sayles has no counsel whatever, except the writer of the present brief; Mr. Cozzens merely asking permission to be heard, without retainer, on account of interests he represents in the extended term of the patent, and any other lawyers in Mr. Sayles' employ being merely local attorneys of record.

The statement the honorable counsel found courage to insert in his own handwriting in the margin of page 61 of his brief, to the effect that his Erie suit was settled for $75, is refuted from the record itself. On turning to his reference on page 635, it will be seen that the $75 was the *verdict of the jury* for the technical damage *proved* to have been *already* committed, the patent then having been granted only two years and three months.

On turning to page 25 of the record, a letter will be found from the attorneys of the defendant, stating that, after the end of the suit, "The defendants thereupon paid in full the judgment which was entered on said verdict for damages and costs, and *also* paid for and took a license under said patent for the residue of its term, *and* paid for *past* infringements not covered by said verdict." The same facts were known to Mr. Sayles, and he swore to them in his bill (p. 8, line 33) in this case, and they were not denied in the answer, and not controverted in the evidence.

The bill in this case, filed in 1861, had attached to it as an exhibit, the plea for the defendant in the Erie case, including the notices of special matter attached thereto, the fourth of which will be seen (p. 23, line 10 to 14) to set up this Stanley-Talson defense, and to give the name and residence of Talson himself. Thus notified of the fact that another defendant had relied upon Talson, this defendant paid no attention to him or his story till six years afterwards, when it secured an opening of the case to let in his testimony as newly discovered! (Decree, p. 34, line 1.) Thereupon it filed an amendment to its answer, (p. 31,) and set up the defense, duly mentioning Talson's name.

This court will wonder how testimony, of which we gave the defendant notice in our bill in 1861 could be newly discovered by it in 1867. The answer, however, is easy. The defendant had "discovered" that Talson would swear to an entirely different state of facts about his alleged brake than he swore to in 1854! In 1854 he swore his brake only ran two or three times over the road, and that *he* then changed it to a *single foot brake.* (Blatchford's deposition, p. 475.) In 1867 he swears it was never taken off the car at all to his knowledge, which extended, as we have seen, for seven years, or till 1849. (Talson's deposition, p. 305, q. 11.)

Of course such flat contradiction destroys all credit, but it does not seem to embarrass the learned counsel on the other side. He calmly ignores Talson's testimony in *this* case as unworthy belief, and founds the defense solely on *our* testimony as to what Judge Blatchford says Talson swore to in the Erie case, in 1854; though elsewhere, (p. 47, line 6 of his brief,) he asserts, with quaint inconsistency, that "Talson is a man of the *highest respectability.*"

Now, bearing in mind that Judge Blatchford is only telling us what Talson swore to, and not as to what the facts were, we will look at the Judge's deposition, to see what the real character of the story was, which was doubtless the strongest Talson had been able to concoct up to that date.

He said, (p. 475,) "A double-acting brake was first put on the New Jersey Railroad, by Isaac Newton Stanley, in 1842. It never went into use. It was so light and *imperfect* that it never answered the purpose. *It had three or four levers in the middle.*"

Thus far *Stanley.* Even if his brake had been successful, and had been patented, our patent, so far from being invalidated by it, would not have even infringed it; because in that event we dispensed with all his middle levers but one, besides differing from his brake in other respects. (See the collection of authorities at the bottom of page 64 of Mr. Payson's own brief.) But Talson further said, "I then took Stanley's brake and threw all his gearing off, and applied it like the Jersey model [a model in the Erie case, but not in this]. That model exhibits a double-action brake, with lever in center, *and the brakes between the wheels worked by a cam on a rock shaft. If you take out the arrangement of the Jersey model within the trucks, and put in Tanner's within the trucks, you will have the Tanner brake.*" Indeed! If the appellant only throws away the part of the Talson combination which was, if possible, a worse truck system than the truck system of Millholland, and which could *not* perform the function required of it, and substitutes therefor the self-adjustable truck system of Tanner, and do that twenty years after the Tanner invention was made, then it will have a brake that will anticipate the Tanner patent!!

When, however, that is permitted by the courts, patents covering combinations of old, or old and new, ingredients, will occupy a very different legal status from that which the law now assigns them. Nobody then will have anything to do, in order to invalidate such a patent, but to pick out one ingredient from one old unsuccessful machine, and another ingredient from another old abandoned machine, and another ingredient from a third old machine that failed to work, and put the three *extracted* ingredients together so as to perform the same *result* as the patented combination, and do this thirty years after the latter was invented. Indeed, a defendant don't even need to do that much. He need put himself to no such expense. He only needs to *remark*, when arguing his case in court, that such a thing *can* be done.

Moreover, Talson did *not* say in 1854 that his brake did or could produce any useful result, and admits it would not even theoretically work as well as ours, and says he abandoned it, and went back to the old single foot brake in a week.

Mr. George Gifford, therefore, though doing his best in 1853 to defeat our patent, was for these reasons able to see nothing in this defense. He therefore wrote to his associate counsel the following letter, which he himself testifies (p. 578) was written after a very careful consideration of all the information he could get from Mr. Talson:

New York, October 11, 1853.

Mr. North—*Dear Sir:* Have you heard from Mr. Grosvenor? I find, on examination of the case, 1st. That Thompson and Bachelder invented the brake as early as 1846 or 1847, (see testimony taken,) *and that the one shown in their drawings filed in* 1847 *is not esssentially changed from the one shown in the drawings of the patent.* 2d. That none of our patents which we have as evidence go further back than 1848. 3d. That *the Talson brake of* 1842 *was barely tried and laid aside, and amounts to such an experiment* as the courts have *often* held to be insufficient to defeat a patent. Now, unless we receive aid from the Eastern testimony of prior use, the chances, in my opinion, will be greatly against us. If we expect to avail ourselves of that testimony, not a day should be lost in dispatching some smart, intelligent person to see those witnesses, and to bring them here and thence to Albany.

Is it not possible that the pliantiff's attorney may not be anxious to try the cause this term; and would it not be well for you to telegraph him, asking whether he expects to try?

I perhaps betray some anxiety about the case; for I realize that we are not, and I fear shall not be ready, and *I do hate a defeat.*

GEO. GIFFORD.

THE NICHOLS BRAKE

The appellant also asserts that our patent is void for want of novelty, because it claims that the essential principles contained in the invention were known and publicly used by one Willard I. Nichols in 1846, upon the New Haven, Hartford and Springfield Railroad, in Connecticut. We admit that Mr. Nichols made and used a brake substantially indentical with ours; but we deny that he did so in 1846, or at any other time till long after our invention was made, in October of that year. The principal question here is one of date; and the burden of proof is on the appellant.

The appellant's witnesses on the subject are three in number, viz., Leppens, Hebard, and Mrs. Allen; while those on behalf of the patent are Stockbridge, Fields, and Hebard.

Leppens testifies, on behalf of the appellant, (p. 146,) that Nichols (who was then master mechanic of the Hartford and New Haven Railroad, but who died in 1850) had occasion to build an extraordinary length baggage car in the fall of 1846, and that to such car, when completed, in March or April, 1847, Mr. Nichols applied the Nichols brake; and that not *more* than three months before it was so applied Mr. Nichols, by means of a stick and four strings, showed Leppens how he proposed to make the brake, and told him that he had *conceived the idea the night before.*

Leppens, therefore, so far from helping the appellant, shows that by no possibility could Nichols have first conceived the idea earlier than December, 1846, which was two months after our invention was made. He is not positive, indeed, that the brake was applied before April, 1847, or conceived more than *one* month prior to that date; so that the appellant cannot claim even Leppens to have sworn that Nichols first conceived his invention till *five months* after ours was made.

The learned counsel evidently thinks that Leppens, his own witness, is not a witness for *him* to rely upon; but rather one whose testimony he needs to explain away, lest the court conclude at once that the defense has no merit. Accordingly, he paraphrases his testimony with a remarkably free hand. For instance, counsel says, "Leppens does not *remember* Nichols showing him the drawings, as stated by Mrs. Nichols." (p. 27 of his brief, line 9 from the bottom.) On turning to the testimony, we find that Leppens remembers that Nichols did *not* show him any such drawings; for he says, (p. 148, line 8,) "He *didn't* show me any drawings. He *never* said anything to me about any drawings." Again counsel remarks, "Leppens also says that when Nichols showed it to him he spoke of it as an invention he had just got up. But no one supposes that this invention was got up by Nichols in a day." On turning to the *testimony*, we see that Leppens swore, (p. 148, line 16,) "Mr. Nichols represented to me that it was something recent,—that *he had conceived it the night before.*" The counsel, though substantially wrong in his quotations from the evidence, makes a true comment upon it, when he says that nobody supposes the invention was got up by Nichols in a day; for Leppens swears that it was conceived in a *night.* But counsel continues: "Nichols 'conceived' the idea in the spring of 1846; had various drawings of it during the summer; finally settled upon the form he liked best, and in that form applied it to a car."

Now, Mrs. Allen, upon whose depositions this statement is based, if it has any foundation at all, says in her *present* deposition (p. 148) that Mr. Nichols made the drawings of *a* brake about January, 1846; or, as she states it, just before and just after the shops were moved from New Haven to Hartford, which, she says, was a month after the Nichols family moved,—which latter event, she says, occurred December 1, 1845.

In her *former* deposition, given in the Erie trial in 1854, eight years nearer the event, she said, (bottom of p. 129,) "I should think he drew that plan in the *fall* of 1846; to the best of my recollection, in the fall of 1846,—late in the fall. It was quite cold weather."

As her *first* deposition puts the date of Nichols making drawings too late to be *useful* and her *second* too early to be *true*, the learned counsel divides the difference, and says the drawings were made in the *summer* of 1846.

It is wholly immaterial, however, *when* they were made; for nobody pretends to have ever seen or heard of them but Mrs. Allen, who says, "Mr. Nichols mentioned to me that it was a brake that he was a-drawing, but I did not *inquire* into it, and did not *understand* what he was drawing." (p. 148, line 7 from bottom.) She also says, "Mr. Nichols often explained it to me as a brake, and said it would dispense with one-half the brakemen. I didn't *understand* then *how* it would, and I don't now." And also, "There was another drawing on the same paper, which represented, as I understood, the brake in a *different way*." (p. 149, line 13.) And again, "*I cannot swear* that the *brake* which he put on the car was not *altered* or *different* from the *drawing* which he took out of the house. He did not tell me that he hadn't altered it." (p. 153, line 16 from bottom.)

Even taking Mrs. Allen's present testimony as correct, which, in view of the former disagreeing statements no court would do, nothing is shown; except that early in 1846 Nichols made drawings of at least two kinds of double brakes. That those drawings bore any resemblance to our patent, there is no evidence whatever. On the contrary, it clearly appears to have been *different;* for both Leppens (p. 148) and Hebard, (p. 157,) the appellant's own witnesses, say Nichols never showed any such drawings to them, but explained to them the brake he put on the car by entirely different means. This is accounted for at once, when we remember that Nichols told Leppens, long after Mrs. Allen says the drawings were made, that he had conceived his brake the night before. It seems, therefore, that Nichols had been *endeavoring* to contrive a double brake for some months; but the drawings he made to represent his first crude ideas were so unsatisfactory to him, that he was ashamed to show them to the workmen, Leppens and Hebard; and when he finally did get the correct idea, it came to him all at once, and was so different from the drawings that they were of no use in representing it, and he therefore explained it by means of a stick and some strings; and did this latter thing, according to the appellant's own witnesses, from two to four months *after* our invention was made; and according to our witnesses more than a *year* after the latter event.

We have shown that the alleged Nichols drawings are of no sort of consequence. The other question is as to the time Nichols first put his brake on a car. The appellant says that Hebard's testimony is "too uncertain to be of much value"; (p. 28, line 14 from bottom;) so that on that point he allows us Leppens, Mrs. Allen, Stockbridge, and Fields, the former two saying it was in the spring of 1847, and the latter two in the spring of 1848, that the brake was first constructed.

Mrs. Allen says, (p. 150, line 5.) "I know that it was previous to the first of May, 1847 [that the car came out with the brake for its experimental trip]. I know from the state of my own health, from delicacy, that it could not have been as late as May when I went out on the piazza and saw the car, as I have before mentioned. *My little girl was born in June*, 1847." The learned counsel makes a great deal of this interesting family event, which, however, seems to have been only *one* of a kind rather frequent with Mrs. Nichols; (p. 148, line 7 of Mrs. Allen's deposition;) but the court will notice that Mrs. Allen's recollection as to the brake is wholly argumentative. She connects it with the birth of her daughter in no way whatever, save that in *her opinion* she could not have been well enough in May, 1847, to have stood on the piazza to see the brake car, or for any other purpose, *because* her daughter was born in June of that year. The birth of her daughter in June, 1847, could not, however, have prevented her from standing on the piazza in the Spring of 1848, which is the time, as we shall show by Stockbridge and Hebard, the brake was first actually put on the car.

This ought to eliminate Mrs. Allen from the case; and it would render any further reference to her, in regard to the present issue, unnecessary, had not the appellant appealed to the court, at the close of its brief on this point, to decide this issue in its favor,—not because it can even claim to have proved the defense with the certainty that the law requires, or indeed to have done anything but to *disprove* it, but, forsooth, because Mr. Tanner and Mr. Sayles endeavored, as the counsel states, to gain the good-will of Mrs. Allen by promising her a handsome present in case the Erie suit of 1854 was decided in favor of the patent, and therein were guilty of bribery!

Mrs. Allen, however, does not claim that Mr. *Sayles* made any such promise, but, on the contrary, explicitly says, (p. 151, line 18,) "Mr. Sayles never made me any compensation for my time, and never *offered* to."

As to Tanner, we have Mrs. Allen's word that he did promise her a handsome present "when his ship came in"; or, rather, when he gained his suit.

It could not, however, have been understood to be in the nature of a bribe; for she did all she could to defeat him in the Erie case, and to defeat Mr. Sayles in this case,—testifying in the former case, (p. 129, line 10 from the bottom,) "I saw the drawing my husband made; *he showed me how it operated.*" This last statement was more prejudicial to the patent than anything she said in her second deposition. In this case, however, she sought to carry the date of the drawings nearly a year farther back that she stated it in the Erie case; but, on the other hand, contradicted her above italicized statement by saying, (p. 149, line 22,) "Mr. Nichols *often* explained it to *be* a brake, and said it would dispense with half the brakemen. I didn't *understand* then *how* it would, and I don't now." And again, (p. 153, line 11 from the bottom,) "I can't give a description of this brake."

Notwithstanding she did all she could to defeat Tanner in the Erie case, even swearing to an important statement which in this case she contradicted, she afterwards applied to him for a fulfillment of his promise,—thus showing that it was not regarded as being contingent on the character of her testimony, but on the result of the suit. Tanner replied in a letter (p. 155) tacitly acknowledging the promise, but saying that Mr. Sayles assumed it when he purchased the patent, and advising her to call on Mr. Sayles for its performance.

She says (p. 151) she accordingly did call on Mr. Sayles, and instead of treating the claim as an *unearned* bribe, and *therefore* refusing to pay it, as he would have done had it been an intended bribe, he merely said that he had not assumed Tanner's debts or promises when he purchased his patent. She adds, (p. 151, line 8,) "I could not *get* Mr. Sayles to promise me anything till he was about leaving. He then said he was going South, and if he should succeed well he *might* give me something himself."

It is with great regret that the writer feels obliged to explain these circumstances; for they seem to reflect very severely an a *woman*. In justice to her, however, it ought to be said that Mrs. Allen's memory is confessedly a weak one, as appears from the numerous discrepancies in her deposition, that could easily be pointed out if it were worth while, and by her own admission on page 154, (line 12 from bottom,) where she says, "I *never* had a very long memory; I do not remember [*now*] near as well as I *used* to."

The lawyer on the other side has compelled us to make this analysis of the truth, by what we have seen are entirely unfounded aspersions on the conduct of the appellee.

Coming for the first time to the Supreme Court, the writer did not expect to find cases argued here as they too frequently are in the remote West, to wit, by abusing the opposite party.

Having thus been compelled to follow the learned counsel for the appellant in his wide detour from the point, the court is now doubtless desirous of being told *when Nichols made his brake.*

On this point, Hebard, the appellant's own witness, swears (p. 157, line 26) that it was first successfully applied one Spring (p. 125, q. 4) by the hands of John Stockbridge—having been experimentally tried on an old car standing in the paint shop during the previous winter—to the first car Nichols ever built for the company; and Stockbridge swears (p. 126, q. 2) to the same effect, and that he never worked for the company at all till April 1, 1848, and that he put on the brake on the new car soon after he began; and that he knows it was April 1, 1848, he began to work for the company from reference to the *books* of the company, as well as his own recollection.

The learned counsel sees, that, unless suppressed, this testimony is fatal to this defense, but he succeeds in ejaculating, "This evidence is purely *hearsay*, and *incompetent*, because the *books* were not *produced*." (p. 28, line 4 from bottom.)

The learned counsel came to the bar soon after the writer of this was born, and therefore has not read the elementary works on evidence so lately as the latter. If he had, he would remember that it is rather too late to interpose a technical objection for the first time when the case is in the Supreme Court of the United States on final appeal; and would know that the objection has no *foundation* even if it had been interposed when the testimony was *taken;* because, inasmuch as the books belonged to a corporation, a stranger to this suit, and were, moreover, a thousand miles away from the jurisdiction of the court below, they *could* not be produced, and that in such cases parol evidence of their contents is admissible.

The testimony of the three mechanics, sums up as follows: Hebard and Stockbridge both say that the latter was the man who constructed the brake, under Nichols' direction, and the latter shows that he did it after April 1, 1848. Leppens shows that it was so applied not *more* than three months after it was first conceived; so that it clearly appears that Leppens and Hebard *at first* merely fixed their unrectified recollection as to the invention one winter further back than it occurred. It follows, therefore, that the Nichols brake was not even *conceived* till at least fifteen months after the Tanner was invented, twelve months after the Bachelder model was made, six months after our patent was applied for, and three months after our brake was successfully operated on a car on the Fitchburg Road.

JOHN TYLER CAR.

The appellant's fourth and last attack on the validity of our patent for want of novelty, is based on the alleged use of a brake precisely like ours on a certain passenger car called the "John Tyler car," on the Camden and Amboy Railroad, as early as June, 1843, and continuously for years thereafter. We insist that no such brake was ever on any car of that road till a considerable time after our invention.

The question is *not*, as stated by the appellant's counsel, whether there was such a brake on that road prior to 1851. With equal propriety, he might say 1861 or 1871. The question is as to whether there was such a brake on that road prior to our invention in October, 1846. This is a very material distinction, inasmuch as eleven of the appellant's witnesses do not *pretend* to know of the brake prior to October, 1846, but do claim to know of it between 1846 and 1851.

The learned counsel devotes exactly four pages of space to these eleven witnesses, and, with a single exception, enlarges and declaims about them precisely as he does about the balance of the great army of railroad employees he so portentiously marshals in battle array.

We cannot consent, however, to allow the appellant's case to be supported by any such devices. We therefore insert here a list of the names and numbers of the eleven witnesses, so that the court may distinguish between the material and the immaterial, without performing the labor otherwise required to sort them out.

No. 4. Letchworth Cox.
No. 8. R. C. Wallcott.
No. 9. John H. Jobes.
No. 12. Thomas Herbert.
No. 18. Joseph Reed.
No. 19. Joseph Hagar.
No. 21. John H. Hillman.
No. 23. Joseph Capner.
No. 26. H. H. Disbrow.
No. 27. Charles Cox.
No. 28. William Disbrow.

Moreover, three of the *strongest* of the eleven witnesses (viz., R. C. Wallcott, No. 8; Joseph Capner, No. 23; and H. H. Disbrow, No. 26) afterward RETRACTED their depositions, and swore they were in error in making the statements they contained about the double brake. (See retractions on pp. 583, 571, and 575 respectively.)

The court will observe, on page 34 of the learned counsel's brief, that he comments upon the testimony of Fielder, No. 11, as being "very convincing," when taken in connection with that of Gamble and Jobes. We have already said that Jobes don't go back of October, 1846, at all; and the counsel himself don't pretend that he goes any further back than into Talson's time; *i. e.*, back to 1849. Therefore, it must be the combination of Fielder and Gamble that is so "convincing" to the learned counsel.

The fact, however, *is*, that neither those men nor Hurd (No. 31) refer in the least to the John Tyler car, or any other car on the Camden and Amboy Road! They refer entirely to the *Stanley-Talson* brake on the *New Jersey Central Road.* Their testimony, such as it is, was taken to bolster up Talson in his *second* deposition, where he says the Stanley-Talson brake was an entire success, and ran at least seven years to his knowledge,—a statement of the case which the learned counsel admits, when discussing the Stanley-Talson brake, (p. 23 of his brief,) to be untrue.

As thus far purged, the grand army of the appellant is reduced from 32 to 18. These *did* swear that our brake was used on the John Tyler car prior to October, 1846, the date of our invention.

Upon the shoulders of these eighteen rested this defense of the Tyler car; a defense to which the appellant's counsel devotes more than thirty-two pages of his argument, being a third more than to all the other five arguments on validity combined; a defense which makes up in dignity what the others so sadly lacked in that attribute; a defense which one thing, and one thing only, could ever hope to overcome. That one thing is *TRUTH.*

Of these eighteen men, the five following were among the most positive, the discussion of their testimony occupying more than three pages of the appellant's argument:

No. 6. CHARLES YUNDT.
No. 7. WILLIAM CRIM.
No. 20. WILLIAM COULTER.
No. 22. JAMES SEEDS.
No. 25. ASHER PANCOAST.

THESE MEN ALSO RETRACTED.

On calm reflection, they concluded they had been in error, and gave depositions to that effect, to be found on pages 559, 600, 611, 602, and 601 respectively.

The counsel, in referring to two of these retractions, (Seeds and Pancoast's,) says, "We are not sure that our case is not helped quite as much as it is injured thereby!" (p. 55, line 21.)

No. 22. Seeds.

Mr. Seeds was *originally* far stronger for the appellant, than any witness who did *not* retract. He said (p. 245) that it was a matter of *positive recollection* with him that the Tyler car had a double brake on in 1844, from *using it daily.* In his retraction, however, (p. 602,) he took it all back, and the appellant neither cross-examined him, nor attempted to throw mud at him afterward. The vials of its wrath were all spent on Pancoast, who originally was even stronger and more *circumstantial* than Seeds. (p. 251, q. 11, 12.)

No. 25. Pancoast.

Pancoast, who was one of the choice spirits of the earth when giving his testimony *for* the appellant, when *he* thinks the matter over and retracts, is accused by the learned counsel of two crimes and one vice, to wit: *Perjury, Bribery,* and *Drunkenness.*

Perjury. To substantiate this charge, the counsel says Pancoast testified that one Ryhow had told him that the patentee had a suit against the Camden and Amboy; whereas there *could* have been no suit, because the road had a license. But that don't prove that Ryhow did not *tell* him there was a suit. But the counsel also says Pancoast was a perjurer, because he afterward said that he understood Mr. Van Rensselaer had paid Mr. Sayles for the right. *That* scarcely proves perjury, because some days elapsed after Pancoast's interview with Ryhow before that with Lockwood, in some one of which, he doubtless learned that Ryhow was mistaken.

Bribery. This charge is based solely on the counsel's allegation that Mr. Sayles was none too good to bribe him. Now, let us see whether this last statement is a warrantable one. The charge is based on four specifications: 1st. The "handsome present" to Mrs. Nichols-Allen; 2d. The $1,000 bond to her; 3d. Sayles' alleged attempt to bribe Lockwood; 4th. Sayles' alleged attempt to bribe Talson. We have, in discussing the Nichols brake, seen that Mr. Sayles had nothing whatever to do with the "handsome present" promise. As to the $1,000 bond, it was given by Tanner in 1851, before either he or Mr. Sayles had ever even heard of the Bachelder and Thompson invention. It was given without Mrs. Nichols' knowledge, or that of Mr. Sayles; and the statement that Mr. Sayles ever assumed to pay it is shown by Tanner's letter to Mrs. Allen (p. 155) to be an entire error. (So also p. 151, line 4.) Moreover, Tanner's motives in giving it were probably rather praiseworthy than blameworthy. (p. 541, x-q. 8.)

The alleged attempted bribery of Lockwood rests wholly on Lockwood's word, whom we shall soon shew by fifty witnesses to be worse than unreliable.

As to his alleged attempt to bribe Talson, it rests on the testimony of Talson and Cudlip.

Talson shows his malice by dragging in the charge quoted by the counsel from page 324, cross-question 203, where it was wholly irresponsive to the question. Moreover, it is an absurd statement, because Talson adds, that accordingly, "When I would begin to advance anything in explanation of the model, the counsel on Mr. Sayles' side would say to me that he did not want me to talk about that,—he wanted me to talk about some other part of the model; the counsel for the railroad company did not sustain me, and I let it go without explanation." It appears, therefore, that what Mr. Sayles bribed him to do, and what he did do, was to *refrain from explaining the model.* Turning to his testimony on that occasion, (p. 475,) it will be seen at once that he *did* explain the model in detail. Moreover, it is barely possible that George Gifford, the attorney for the defendant, could have explained the model to the jury without Talson's aid. (See also p. 490, q. 2.)

Cudlip is positively contradicted by Mr. Sayles, (p. 589, q. 3, 4, 8,) by Isaac P. Wendell, (p. 580, q. 11,) and by David H. Baker. (p. 607, q. 1 to 14.) This last gentleman succeeded Talson as master car builder on the New Jersey Road in 1849, and continued to hold the position up to the time of the giving of his deposition, in 1868. He has testified three times to the truth, in our behalf, on various points in this case, though, as he says, (p. 608, q. 7 to 11,) he has always done so against his will, for fear of offending his employer, the railroad company. Moreover, Cudlip is circumstantially shown by Reilly (p. 611, q. 1 to 9) to be a criminal in money matters. His testimony against Mr. Sayles doubtless sprang from keen disappointment, because he could not *get* Mr. Sayles to bribe either him or Talson, his relative.

From the foregoing references to the proofs in the case, it would seem that the honorable counsel for the appellant might have omitted from his argument these charges against Mr. Sayles, and still have done the whole duty which a client has a *right* to expect from a counselor.

Drunkenness. This charge against Pancoast is based solely on Lockwood's statement, upon whose veracity we still have to comment at large. Mrs. Pancoast swears (p. 626, q. 7 and 8) that her husband had not for 30 years spent an average of half a dozen evenings a week away from home, and had never been under the influence of liquor but three times in the 30 years, and then only slightly so. She adds, that Mr. Pancoast was, and had been for 14 years, a member of the Methodist Episcopal Church in Camden.

The charge of the honorable counsel, at the top of page 57 of his brief, that Pancoast "had left the path of truth," seems rather to have shifted, and to be quite applicable to his own witnesses, and quite inapplicable to Pancoast.

Strenuous endeavor was made by Thompson, (appellant's witness No. 2,) whom the learned counsel cordially indorses, because he has been Mayor of Bordentown, and also member of the Legislature—strenuous endeavor, we say, was made by Thompson to reclaim Pancoast to the path not of truth, but of Lockwood and

Thompson, truth or no truth. The dialogue between them may be found on page 624, q. 10 of the record, and is as follows:

"*Thompson.* 'Pancoast, how are you? I am glad to see you. You are the man I have been looking for all day. I have been over to your house. What I was going to say is about that brake. You have put myself and Lockwood in a bad fix.'

"*Pancoast.* 'I don't know what kind of a fix you are in, but *I know I was mistaken* when I came to talk with my old men I had railroaded with."

"*Thompson.* 'Oh, I suppose Mr. Sayles has paid you, or promised you, like he has some of the rest, twenty per cent. of the patent.'

"*Pancoast.* 'Mr. Sayles never promised me a cent, but I suppose every man has his price?'

[N. B.—So far from reflecting on Mr. Sayles, the context shows that Pancoast was doing a little detective work, in order to ascertain whether Thompson's great anxiety to find him meant *bribery from the railroad.* And, moreover, he was successful; for the offer to bribe came at once; not, indeed, in the form of money, but a situation as engineer, which was the very thing he most needed at that time, and could not get, though he obtained an excellent one afterward, and prior to this deposition. Thompson said:]

"*Thompson.* 'You had better go back to the company; you were brought up there.'

"*Pancoast.* 'I don't care about the company, nor anybody else. I WANT EVERY MAN TO HAVE HIS RIGHTS.'

No. 7. Crim.

The counsel for the appellant misses the point of this man's retraction, confining his criticism to collateral matter. Let us see what Crim says about the John Tyler car, which is the only passenger car the learned counsel claims had the double brake on prior to 1846. (Top of p. 31 of his brief.) We print here exactly what Crim said about that car, when testifying for the appellant. (p. 206.)

"Q. 10. Do you know anything about the use of a car on that road, called the John Tyler? If so, what was there peculiar about it that makes you remember the case?

"A. The car was called the John Tyler, and it had different seats from what cars have nowadays; they worked on a pivot; some were round, some arm-chairs, and different shapes.

"Q. 11. Do you know, of your own personal knowledge, that there was in use upon said John Tyler car, in the year 1845 or 1846, a double-acting brake, like the one here on model Exhibit A?

"A. Yes, sir."

The retraction of this witness was not brought about, as the counsel says, by merely looking at a car on the Camden and Amboy Road. On the contrary, it, together with that of Yundt, his companion, was chiefly brought about by reflecting on the matter on their way home from New York, where they had been testifying for the appellant.

Notice the material part of the language of the retracting deposition (p. 600):

"Q. 1. Have you been examined before, in this case, on the subject of brakes on the Camden and Amboy Road?

"A. Yes, sir.

"Q. 2. Was that examination in New York?

"A. Yes, sir.

"Q. 3. When you were returning home from examination, who was with you?

"A. Charles Yundt.

"Q. 4. When so returning with said Yundt, did you talk over your examination in New York? And if so, did you come to any conclusion about it? And if so, what was the conclusion?

"A. Yes, sir, we did talk it over. I told Yundt I thought we were both *mistaken*. We had both spoken about double brakes; and I told him I thought they were not connected so that one truck would work with the other. They were *separate* brakes.

"Q. 5. Now that you have thought the matter over, state what kind of a brake you now say was on the John Tyler car.

"A. Well, sir, it was *called* a double brake; but this double brake, as it was *called*, had a brake at both ends of the car, and each brake was separate; and one brake did *not* brake all the wheels. *One* brake broke on *one* truck.

"Q. 9. Will you state how many brakemen you now say were required to put on all the brakes at the same time on the John Tyler car?

"A. It took *two* brakemen—one at *each* end."

Cross-examination waived by counsel for defendant.

No. 6. YUNDT.

This man is Crim's companion witness, both in his original deposition and in his retraction.

As to Yundt, however, there was a sequel that did not occur in Crim's case. Like Pancoast, he was subjected to the blandishments of Thompson, which he at first resented with vigor, and even with profanity, (p. 633, line 8,) but to which he afterward yielded so far as to reply as follows, to a question from the appellant's counsel (p. 631):

"X-Q. 5. Did this brake [on the Tyler car] operate on both trucks at the same time?

"A. I *think* it did, to the best of my knowledge."

Prior to this last deposition, however, but some months after the retraction of his first deposition, he very explicitly reiterated the statements of the retraction, in the presence of Wendell (p. 631) and of Hubbard (p. 632).

No. 20. COULTER.

This witness also retracted, though that fact would never be guessed fron reading the brief of the learned counsel for the appellant. More space and emphasis are devoted in that brief to Coulter's deposition than to any other of the eighteen except Pancoast, who, as we have seen, *also* retracted.

Coulter was inquired of by the appellant about certain circumstances alleged to have occurred on the Tyler car in the Fall of 1845 or the spring of 1846. These were the "hitting on the hand" circumstances, and are alleged by the appellant's counsel to have been identical in character with those alleged to have occurred to James C. Hillman on the same car in August, 1845, and to John H. Hillman in May, 1848. To save repetition, we will explain that matter when we come to discuss James C. Hillman's testimony.

Without regard, however, to those circumstances, Coulter positively swore of his own knowledge that the brake which was on the Tyler car when that incident of the "hitting of the hand" occurred, did apply the power to both trucks at the same time. (p. 240, q. 5 and 6.)

His retraction is to be found on page 611, where, being asked "What kind of a brake do you think was on that car?" he replied, "It is impossible for me to tell."

THE FAITHFUL THIRTEEN.

We have thus shown, that of the 32 witnesses with which the counsel started out, 14 were wholly immaterial, and 5 of the very strongest of the material 18 retracted, leaving 13 still to be considered.

No. 1. Lockwood.

He swears that the brake was put on the Tyler car in May or June, 1843, where it continued in use till the fall of 1865, *and that it was applied to all the passenger and baggage cars on the road as fast as the latter could be spared off the road for that purpose.* (p. 169, q. 5.)

That this story is purely a work of the imagination, we will now arrange the evidence to show.

First. Henry Tanner says (p. 536, q. 4) that he visited Lockwood in 1851, to try to induce him to buy the right to use the Charles B. Turner double brake, (the invention heretofore sufficiently described,) and Lockwood declined to do so, because he was about adopting the Hodge. He further says (p. 539, q. 2, 3, 4, re-direct,) that the model he showed Lockwood on this occasion was identical with the Tanner brake. That being the case, it was identical with what Lockwood *now* claims he himself applied to the Tyler car in 1843. Tanner also says (p. 538, q. 19) that during that interview Lockwood said no solitary word about having himself used the same thing in 1843, or after that time.

Second. Mr. Sayles, the appellee in this case, testifies (p. 454, q. 2 to 6) that he called on Lockwood in the summer of 1852, with the letters-patent for the Tanner brake, for the purpose of inducing him to buy the right to use it on the Camden and Amboy Road, and that Lockwood told him Tanner had called on him with a model of the same thing some time before, but did not say anything about such a form of brake having been used on his road. Mr. Sayles also says (q. 7 to 9) that in 1853, after the Stanley-Talson defense had been set up by the defendant in the case of Tanner *v.* The New York and Erie Railroad Co., he went to New Jersey to learn the facts, and, calling on Lockwood again, was told by him that he had never seen anything of that or any other double brake till he saw the Hodge some two or three years before; *i. e.*, in 1850 or 1851.

Third. Francis A. Stevens, a witness calmly ignored by the learned counsel, though the brake he invented is much extolled by him, testifies (p. 513, q. 7 to 13) that *he* went to Lockwood about 1854, for the double purpose of introducing his brake and getting evidence to defeat our patent, but never heard a word from him about any use of a double brake prior to our invention.

Fourth. Henry Waterman testifies (p. 464, q. 3) that in 1859, when trying to obtain evidence to defeat the Hodge patent, *he* called on Lockwood, and was informed by him that they *commenced* with double brakes on their road with the Hodge, and afterwards took it off and put on the Tanner, and found it worked better than the Hodge. He adds, (p. 466, q. 2, re-direct,) that Lockwood said nothing whatever about having used the center long brake in 1843.

Fifth. William Wheeler Hubbell testifies (p. 546, q. 21 and 24) that, when diligently searching for information to defeat our patent, in 1860, he called on Lockwood, and learned from him that the first double brake used on the Camden and Amboy Road was the Hodge, with swinging levers, and the time when it was first used was about 1851.

Sixth. Lockwood himself says (p. 169):

"Q. 4. How long were said brakes in use on the Tyler car?

"A. From the time they were put on in 1843, until the car was destroyed some two years ago last fall, [*i. e.*, fall of 1864,] as unfit for use.

"Q. 5. Was the brake applied to other cars on the Camden and Amboy Road? And if so, to what extent?

"A. They were applied to other cars. We applied it to a crate car for carrying *baggage*, *directly* after that. We continued *then* putting it on *all* our cars for passenger and baggage use, as we could spare them off the road. At that time our cars were very limited, and when we took *any* of them in for repairs we applied the brake."

Here is a statement that the learned counsel don't even *pretend* is true.

Fifty-one witnesses were called, on both sides, as to the use of the double brake on that road prior to 1851; and the learned counsel has not been able to find *one man* who does not diametrically disagree with Lockwood in his positive statement about a matter that, if it occurred, was so open and noteworthy that it is not *possible* that Lockwood could have been the only man who knew it out of the fifty-one.

The learned counsel carefully omitted this sweeping assertion from his epitome of Lockwood's deposition. He knows very well that he can never drag any such testimony as *that* through the Supreme Court, and therefore he does not attempt it.

In what Lockwood says about the putting on of the crate-car brake after it was put on the Tyler car, five only of the faithful thirteen agree with him. As, however, they all place the crate-car brake subsequent to the other, our evidence, which negatives the statement that it was on the Tyler car prior to our invention, must also disprove the claim that it was on the crate car before that time.

Out of the mouths of *five* witnesses comes the unanimous testimony, that shows, that, so far from Lockwood's story being true, he *knew* that no double brake was used on his road prior to our invention. Out of his *own* mouth comes a story which not one other of the appellant's witnesses would indorse, and which all of our witnesses together clearly disprove.

Dripps, another of the thirteen, also told Hubbell, (p. 546, q. 21,) about the same time that Lockwood did, that no double brakes were used on the Camden and Amboy Road prior to the introduction of the Hodge, in 1851.

We will now review the testimony of the eleven subordinate mechanics who say they remember the brake as being on the car prior to October, 1846, the date of our invention.

Stockham, (p. 227, q. 5,) Dunn, (p. 231, q. 3 and 4,) N. F. Smith, (p. 184, q. 4,) and Venable (p. 190, q. 7) claim first to have seen the brake on it when it was being retrimmed, repaired, and repainted, "during the winter of 1844–45," as Dunn says.

Now, it is impossible to believe that the Tyler car, which nearly all the witnesses on both sides agree was fitted up with unprecedented expense and completeness in June, 1843, should need to be refitted and repainted "during the winter of 1844–45," only a year and a half afterward.

Those four men are simply mistaken as to the time; for Thompson, the appellant's own witness, shows (p. 181, x-q. 20–23) she was not overhauled the second time *earlier than* 1849.

Thompson also says he furnished the trimmings for the car in 1843, and again in 1849, and perhaps several times after the latter date. He only claims to have noticed the brake on one of these occasions. With what convincing certainty can he say, after the lapse of a quarter of a century, that it was not one of the last of these times, and not the first, that he did so?

Buzby says (p. 270, q. 2) that he was employed in the Camden and Amboy office as a clerk and time-keeper from 1840 till 1867, and that (q. 12) on one occasion he noticed that the Tyler car had a double brake on, after being refitted. Living, as he did, a perfectly monotonous life for twenty-seven years, and noticing, as he doubtless did, the Tyler car after *all* of its refittings, he strains our credulity very greatly in asking us to believe he can remember on which of these remote occasions it was that he first saw the double brake upon it.

Bogy (p. 266, q. 2) says he was a brakeman for five years, beginning July 4, 1843, and that some time during that period he saw a double brake. As in order to affect our patent it would have to be in the first half of this period, Mr. Whipple pressed him to be more definite, whereupon he said it was "along in 1844 and 1845." How can he say, after twenty years, that it was not "along" in 1846 or 1847, or even much later?

James C. Hillman. This witness says that in August, 1845, when he was a boy of fourteen, he "made a practice of being around the railroad" when out of school, (not a practice very well calculated to lay the foundation for habits of veracity, as we shall see,) and that on one of these occasions he and other boys of the same sort got around the Tyler car one day and commenced "fooling with the brakes," in the course of which "fooling" he was struck in the side with the brake handle, and it gave him a pretty "severe lick." He continues: "My inquiry was, then, who done it and what done it, and the boy told me, on the other end, that *he pulled* the brake out of my hand."

In commenting upon this, as proof that the car must have had on the Tanner brake, the learned counsel says: "If this evidence is not true, there is no use in ever trying to prove anything!" In fact, it is as "convincing" to the learned counsel as was the testimony of Fielder and Gamble. It, however, requires only a glance at the Tanner model to see that it is wholly impossible for a person at one end of the car to *pull* the brake out of the hand of a person at the other end. The effect of "pulling" on one windlass is not to *tighten*, but to *loosen* the connection between the center lever and the other windlass. This explanation also disposes of the labored argument the learned counsel based on the same alleged facts in the case of Coulter, and disposes of it on the very principles he there lays down. He there says: "The appellant did not offer Coulter as a philosopher, but simply to tell the facts. Any one can prove a fact, though it may take a philosopher to explain it." So, also, any one can bear false witness; but in the case at bar it don't take a philosopher to disprove the statement. The moment one ceases to *assume*, and begins to *think*, it appears at once that no such *pulling* as Hillman swears to could have occurred with the Tanner, or alleged Tyler car brake.

When the learned counsel reads this brief, which will be filed three days before the argument, he will no doubt attempt a change of base on this point, and will claim, on the hearing, that it was the *letting go*, and not the *pulling*, that gave Hillman the "pretty severe lick." If he does this, however, he will only avoid Scylla to be wrecked upon Charybdis, because Hillman says it was the *pulling*, and his brother (John H. Hillman, who is one of the 11 immaterial, though doubtless untrue or mistaken witnesses, heretofore referred to) puts his knowledge of the double brake on the same ground. He says: "In May, 1848, I was coming from Philadelphia to Trenton. I was asked to help put on the brake, by the conductor. I took hold of the crank of the brake, and felt another person *drawing* the brake at the other end of the car." (p. 243, q. 7.)

Now, under no possible circumstances could a person at one end of a car, with the Tanner brake, either "pull," as James C. Hillman says, or "draw," as John

H. Hillman says, against or from a person having hold of the windlass or crank at the other end. Such a result *would* follow from such a cause with the *Hodge* brake, and did so happen in 1851 with Jeffries, to whom the counsel refers as corroborating the theory adopted by the Hillmans. That circumstance explains the whole matter. The conspirators, seeking to invent a plausible story, made experiments with the Hodge brake, which was the double brake nearest at hand; and found that a man at one windlass could "pull" or "draw" against the man at the other, and jumped to the conclusion that it would do so with *any* double brake. They thereupon contrived this story so as to secure belief, quite unmindful of the fact that "the practice of being around the railroad when out of school," though well calculated to teach them to bear false witness, was not so well adapted to make them do so skilfully. The Hillman brothers illustrate anew the fact that *truth* cannot be successfully counterfeited.

Coulter seems to have been troubled in his mind after he gave *his* "hitting of the hand" deposition, and made some experiments with the different double brakes, with the result of finding that it was the *letting go*, and not the *pulling*, that could cause such a result with the Tanner brake. He accordingly did two things, to extricate himself from the position in which his deposition was then seen to place him. That part of it in which he stated that he learned, after the "hitting of the hand" incident, that the car had the Tanner brake on, he retracted. That part about the "hitting of the hand" he patched up. One year and twenty-eight days after his first deposition, he gave another, saying that it was the *letting go* that caused the "hitting of the hand." When asked how he *knew* "letting go" would have that effect with the Tanner brake, he said, "I have experimented with it since." (p. 340, q. 5.) He therefore adds a great many new statements about "the hitting of the hand" incident, in order to make it conform to the "*letting go*" theory. He evidently knew nothing of these when he gave his first deposition; for he there both said and showed that what he had to say was "*very brief*."

Joseph Head. This witness gave a deposition which was, on the *direct* examination, altogether more invulnerable than that given by any other of the defendant's faithful thirteen. Only five questions were put to him, and the answers he gave, unlike those of every other of the thirteen, made out a case without a flaw. The learned counsel for the appellant very justly remarks, when commenting upon that direct examination, "Here is a witness whose testimony it *seems* impossible to doubt." When, however, he came to the *cross*-examination, Head suffered total shipwreck. Observe his deposition, on page 236 of the record:

"X-Q. 22. While you knew this Tyler car, where did it run to?

"A. It ran on the mail partly, and partly on the Trenton way train, and stopped there and went no further.

"X-Q. 25. While you knew about it, did it run on any other kind of trains than the mail and way trains?

"A. Not as long as *I* had charge of it.

"X-Q. 26. Now, what is the best information you can give us as to how long you had charge of it?

"A. Well, I should judge I had it from five to six years, counting from 1845; but I can't speak positively."

When he speaks of 1845, he means March of that year, when he carefully proves, by a letter of the 21st day of that month, he took charge of the Tyler car.

The learned counsel, however, required to sustain B. L. Wallcott, whose testimony refers to seeing the Tyler car a few weeks after his marriage, in April, 1845, (p. 216, q. 3,) *upon an entirely different train* from either of those Head swore she ran upon exclusively, viz., an excursion train upon an entirely different branch of railroad.

In order to do this, he has laboriously analyzed the testimony of ten witnesses, who swear the car ran in that excursion train a large share of the time during all the six years referred to by Head!

The appellant's counsel could not have *both* Head and B. L. Wallcott, and he concluded to give up Head. It is probably these two witnesses he refers to on page 45 of his brief, when, in summing up the merits of the case, he says:

"*Third.* In the midst of all this diversity, these witnesses yet preserve the most remarkable unity and harmony as to all those matters upon which *any two* of them *happen* to testify."

B. L. Wallcott, though purchased, as he was, at the great cost of giving up his splendid witness, Joseph Head, can never be other than a disappointment to the learned counsel.

To show that this is the case, we will exhibit one of his many self-contradictions. First observe the following, on page 218:

"X-Q. 38. Did not Mr. Lockwood say anything at all to you when he first spoke to you concerning the Tyler car, about wanting to know what brakes it had?

"A. Yes, sir; he asked me if I knew what kind of brakes the Tyler car had on, and I told him I would have to *study* a little."

Now observe the following, on page 222:

"X-Q. 77. Are you *sure* that he [Lockwood] did *not*, at that first interview, say anything more to you than to remark that he wished you would study up what you could about the Tyler *car?*

"A. That is all he said. He said no more.

"X-Q. 78. Do you swear positively to that?

"A. Yes, sir.

"X-Q. 79. Did he not say anything to you, in that interview, about the *brakes* of the car?

"A. *He did not!*

"X-Q. 80. Will you swear positively that he did not say anything at all to you about the brakes at that time?

"A. He did not, at that time. I will swear *positively* to that."

It will be seen that this strange stultification is consistent neither with sound veracity nor good recollection. In the *absence* of both those qualities, it can *easily* be accounted for. In the earlier part of his cross-examination, he had said that, when first visited by Lockwood and inquired of about the brakes on the Tyler car, he told Lockwood he would have to "study" before he could tell him. Seeing, as the cross-examination progressed, that it was asking a good deal to require people to believe that he could be *positive* of so improbable a statement as that the double brake *was* on that car a quarter of a century before, he endeavored to show, in response to cross-question 75, that he was a man gifted with extraordinary powers of memory. Accordingly, he rehearsed what he said he had told Lockwood about the minute details of the car before he had any hint from Lockwood as to which of these particulars he required information upon. In order to impress everybody with the genuineness of the recital, he inserts the description of the alleged brake as number 12 in a list of thirteen particulars. He still further overdoes the matter, by giving the most minute description of the parts of the brake, even remarking the length in *inches* of a particular chain, and the exact arrangement of every part of our patent; and then he triumphantly said he was able to recall all these particulars to mind, and did enumerate them to Lockwood, without Lockwood having lisped a syllable about the brakes. So far, however, from possessing such a Herculean memory as would be required to carry all those minute particulars of a machine so many years, he did not even remember that he had sworn within an hour that Lockwood asked him about brakes the first thing; and he told Lockwood he could tell him nothing without study!

And this is the witness whose cross-examination the learned counsel says (p. 35, line 22) "proved still more clearly the fullness and accuracy of his recollection."

It is *this* witness also, together with James C. Hillman and Coulter, two of the "hitting of the hand" witnesses, and Charles Cox, who don't pretend to know anything about *what* brakes were used till February, 1848, that the learned counsel selects and sets up at the end of his argument as the corner-stones of the Tyler car defense.

The counsel omits Talson from among his witnesses, notwithstanding he denominates him (p. 47, line 6) as a man of the "highest respectability," and notwithstanding he swore this defense through without an outward-appearing qualm. (p. 306, q. 15.) The learned counsel, however, evidently thinks that Talson's testimony is incredible, for many reasons, among which are these: 1. He is a proved perjurer, on the testimony of Judge Blatchford, as we have seen in a previous part of this brief, while discussing the Stanley-Talson defense. 2. George Gifford, (p. 522, q. 6 to 10,) Thomas M. North, (p. 495, q. 8 to 14,) and W. W. Hubbell (p. 544, q. 10) all testify that they made strenuous efforts to secure evidence to defeat our patent in 1853, and to that end applied to this same Talson for information of prior use; and that though Talson was very willing, and even anxious, to help them, he never said a word to either of them about any knowledge of prior use on the Tyler car.

Thus, out of their own mouths, the appellee has refuted, or shown to be wholly unreliable or immaterial, every one of the appellant's witnesses on this issue, save *Conover*. *He* was no doubt *intentionally* wicked. We base this statement on two grounds: 1. The avidity with which he positively swore to all the particulars he thought would be useful to the appellant, before his interrogator had asked him a word about brakes, or even mentioned the subject. 2. His refusal to give any *definite* answer to any collateral question, lest he should furnish material for disproving the main statement. These are some of the symptoms of perjury. In his opinion of 1871, (p. 67, par. 4,) Judge Drummond said: "I think that the witnesses who state that the double brake, combining the two trucks in the manner of the Tanner patent, was on the John Tyler car in 1843, are mistaken, or testify untruly." No doubt his honor placed Lockwood, Talson, Dripps, Conover, Head, B. L. Wallcott, and James C. Hillman, in the latter category, and all the others in the former.

APPELLEE'S PROOFS.

The learned counsel for the appellant complains of our testimony because it is *negative*. We reply, that it is negative *only* as truth is the negation of falsehood, and in the sense only in which learning is the negation of ignorance, and virtue of corruption. In every other sense, it is as *positive* in kind, and more so in *degree*, than that of the appellant.

William Quigley.

William Quigley began in 1843, at the age of 18, to work as extra brakeman on the Camden and Amboy Road, acting as such once or twice a week (p. 477, q. 2, p. 562, x-q. 18) until 1847, when he became a regular brakeman for some years, and then a fireman, and then a brakeman again, and then an engineer on the road, which was his employment when, after twenty-five consecutive years of service, he gave in 1868 his deposition for the appellee. He was, from 1843 onward, almost as familiar with the Tyler car as the Justices of the Supreme Court are with their robes, (p. 479, q. 25; p. 484, re-direct q. 2,) and knew very well indeed that it was necessary to actuate *both* windlasses on the car, in order to apply all the brakes. (p. 477, q. 7; p. 479, q. 34.)

He says: "There were brakes on each end of the car, applied *separately* to each truck." (p. 479, q. 7.)

The testimony of this gentleman (and to show that he *was* a gentleman, we call attention to the excellent tone of his answers on cross-examination: p. 480, x-q. 9 to 26) is indeed negative testimony, in that it is sufficient of itself to negative the whole Tyler car defense; but the *manner* in which it does so is remarkably *positive*.

The learned counsel can say only two things against Quigley's testimony:

1st. He says that his testimony would at once be received as true, if it were not contradicted by at least *twenty* witnesses for the appellant, every one of whom is at least as good as he. (p. 50.) We have already seen, however, that the appellant has, all told, but *thirteen* material witnesses who did not *retract*. Of those, five (viz., Thompson, Stockham, Smith, Venable, and Dunn) only claim to have seen the brake *once* or twice, and that casually, while the car was in the shop being overhauled, as most of them say, in the winter of 1844–45; but which overhauling Thompson himself shows did not occur till several years afterward, and long after our invention was made.

The learned counsel evidently does not mean *that* set of men, when comparing his witnesses with Quigley.

Neither can he mean Lockwood, Talson, or Dripps; for, unlike Quigley, they had often told people precisely the reverse of that to which they now swear. Nor could he have intended to refer to J. C. Hillman; for *he* is contradicted by an obvious *fact*, which he forgot to take into account when making up his story.

Nor can he refer to Head or Buzby; for they never were either train men or mechanics, and the former is contradicted by ten witnesses on an important collateral point, and the latter only claims to have noticed the brake *once* during his monotonous service of 27 years on the road as time-keeper and clerk. Nor can he refer to Conover; for even the learned counsel himself can indorse him no further than to say he was *presumably* honest. (p. 37.) He *must* refer to the only two remaining men, B. L. Wallcott and Bogy. They were the only two *brakemen* out of the whole faithful thirteen of the appellant.

Bogy (who signed his deposition with a X) can only say (p. 267, q. 5) that he observed the double brake "along" in 1844 and 1845.

B. L. Wallcott could remember nothing about the brake till he had time to "study on it a little." (p. 218, x-q. 38.)

We submit to the court, however, whether Quigley is not more *definite* than *Bogy*, and call attention to the fact that he was not "seen," as *Wallcott* was.

It appears that at the time the Lockwood-Talson Tyler car conspiracy was sweeping into its ranks the simple-minded and dependent mechanics and clerks on the Camden and Amboy Road, it came to the ears of the appellee that there was an engineer by the name of Quigley who had declined to "remember" that the Tanner brake was on the Tyler car a few years *before* our invention, instead of a few years *after*. Knowing his own methods, however, the agent for the appellant (Mr. Whipple) naturally supposed that Quigley had been "seen" by Mr. Sayles. Accordingly, when all other means of scathing him on cross-examination failed, the following dialogue took place (p. 483):

"X-Q. 58. Who first called your attention to testifying in this case?

"A. I was subpœnaed to do so.

"X-Q. 59. By whom?

"A. By the prosecutor.

"X-Q. 60. Who is the prosecutor?

"A. This gentleman who sits here at the corner of the table. I do not remember his name.

"X-Q. 61. Did Mr. Sayles, who sits at the corner of this table, serve the subpæna upon you? If not, who did?

"A. He sent it to me by mail.

"X-Q. 62. Have you had conversation, with regard to your evidence in this case, with any person or persons before you came into this room?

"A. Nothing further than on the road among our own men, about the different brakes; how they worked, &c., &c."

The appellant was so much disturbed by this testimony of a long-trusted railroad engineer, that its indefatigable agent (Mr. Whipple) made diligent search for material with which to contradict him on some one or more of the collateral matters to which he testified with great freedom, in a deposition composed of 41 direct and 72 cross questions and answers. Not a flaw or inconsistency could, however, be discovered, as is substantially confessed by the learned counsel, who refrains wholly from referring to the fact, that the appellant's agent (Mr. Whipple) took pains to prove, that whereas Mr. Quigley said in his deposition he was 43 years old, one Peter Bloomsburg, whom "common report" had it, was Quigley's "uncle by marriage," had told one Burgby that Quigley's age was 41!

We have selected this deposition for analysis, rather than some other, chiefly because Mr. Quigley is the witness whom the appellant made the most strenuous efforts to break down.

In view of the law that a defense of want of novelty must, when set up against a patent, to be successful, be proven *beyond a reasonable doubt*, as distinguished from a mere *preponderance of evidence*, we claim that the Tyler car defense falls *of its own weight*. We have shown that it carries *within* it the dynamite that must blow it to fragments.

We have not, however, refrained from proving the *contrary* of what the appellant *alleges*, but has *not*, and could not *prove*. Quigley's deposition is a sample of our testimony, more indisputable than the average it is true, but still a sample. It is unnecessary for us to analyze it all. We will simply classify it, remarking that the learned counsel, in reviewing our depositions, includes several of such a collateral character that we never once thought of mentioning them in our brief, and takes evident delight in showing that not *all* of the thirty brakemen, firemen, conductors, and engineers whom truth compelled to testify in our behalf, are as positive, circumstantial, and unassailable as Mr. Quigley. In addition to him, however, there are *twenty-two admissible witnesses for the appellee*.

They are divisible into four classes, in respect of weight.

First. Four men who positively swear that no double connected brake was ever on the Tyler car till about 1850. They are Condit, (p. 437, q. 13,) Hutton, (p. 388, q. 22, 23, and 24,) Pancoast, (p. 601, q. 2, 3, and 4,) and Van Syckel (p. 506, q. 11 to 15.)

Second. Four men who say that they were acquainted with the Tyler car from 1843 till 1850, and that, to the "best of their knowledge," it had nothing but a single acting brake upon it during those years. They are Morris, (p. 391, q. 17, 18, and 19,) Crim, (p. 601, q. 9,) Seeds, (p. 603, q. 4,) and Seward (p. 563, q. 7.)

Third. Seven men who had ample opportunity and reason for seeing the double brake if it had been on *any* car of the Camden and Amboy Road at any time during those years, and did not see it. They are McFarland, (p. 469,) O'Mahoney, (p. 432,) Reid, (p. 416,) Van Houten, (p. 525,) Ward, (p. 425,) Briggs, (p. 533,) and Frisbee (p. 552.)

Fourth. Seven men who were each acquainted with the Tyler car for various lengths of time, ranging from two to five years, between 1843 and 1850, and all of whom testify positively that there was no double brake on it during those periods. Herbert's acquaintance was from 1843 to 1845. All other portions of the time are covered by at least two out of the remaining six, and from 1846 to 1850 by at least three.

The names of the seven witnesses are Herbert, (p. 564,) Jefferies, (p. 409,) Teese, (p. 572,) Counsellor, (p. 516,) Flannegan, (p. 556,) Nostrand, (p. 530,) and Moore (p. 443.)

GENERAL REMARKS.

First. Frequently, throughout his brief, the learned counsel quotes from an oral argument delivered in 1869, for the complainant, in the court below. By means of extracting such sentences as are suitable for the purpose, he is able to create, set up, and knock down in the course of ninety-five pages, many a man of straw.

An instance of the kind occurs in the second paragraph from the top of page 46—a paragraph which all must heartily confess is a rhetorical *gem*.

Second. The complainant, in order to break the force of the five witnesses who testify to Lockwood's previous statements contradictory to his present oath, attacks the veracity of Henry Waterman, the eminent mechanical engineer, who is also probably known to the court. The insincerity of this attack is shown, however, by the fact that the appellant itself afterwards called him as a witness on another point in the case. It hardly accords with the rule to attack the veracity of a man, and in the same breath offer him to the court as a witness, and thus indorse his veracity.

Third. For the same purpose, also, it attacks the appellee, saying: "Sayles has testified in this case over and over again, and has been contradicted every time." The record shows that he has testified but once in this case, except on this Talson-Lockwood conspiracy; and that so far from being contradicted every time, he has himself contradicted the conspirators, Talson, Lockwood, Dripps, and Cudlip, and in so doing has been *corroborated* by Samuel Blatchford, George Gifford, C. M. Keller, Thomas M. North, Wm. Wheeler Hubbell, Francis A. Stevens, Isaac P. Wendell, Thomas P. Grosvenor, David H. Baker, Mark C. Hubbard, and Henry Waterman, not one of whom had any interest in the suit, either as counsel or otherwise, and five of whom had—or had formerly—interests against the complainant's patent.

Fourth. The learned counsel also says, (p. 45,) "If our evidence is not true, we think the court will agree with us that this is one of the most extraordinary cases of wholesale perjury ever known." It is indeed *one* such case; but there is another case, in this very record, even *more* extraordinary, of which the court is now about to learn the first. The Tyler car is not the *only* conspiracy in the case in behalf of the appellant. There is another bolder, more positive, and on its *face* far stronger and more dangerous than it, viz.:

THE LONG ISLAND CONSPIRACY.

The testimony in the Long Island matter was all worked up and taken, on behalf of the appellant, by Stephen M. Whipple, the *same man* who managed the entire Tyler car and Stanley-Talson defenses, to whom, however, the learned counsel's brief contains not the most distant allusion.

The writer of this had prepared his brief on the Long Island defense before he was informed, in April last, that the honorable counsel who has charge of the case for the appellant in this court had concluded to abandon it, as unworthy of belief.

We will insert herein the analysis of the testimony that brief contained, as a further way of meeting the learned counsel's argument, that the Tyler car defense is necessarily true, because thirteen men swore to it.

Six men swore to the Long Island defense, and, unlike several of the thirteen Tyler car men, not one of them could be contradicted out of his own mouth.

The story, however, was shown to be so utterly false, that even the indefatigable counsel for the appellant, who never omits a possible point, either small or large, abandoned it, and does not even mention it in his brief.

Here follows the original analysis of the testimony on both sides, just as it was prepared for the printer, when we supposed it would have to be argued on its merits:

The record contains six depositions on each side of this question. Let us first review those on behalf of the appellant.

Van Voorhis, a street-car conductor, says he had charge of the repairs of the cars on the Long Island Road from May, 1843, till some time in 1846, and that in the summer of 1845 a brake precisely like ours was put on one of the cars of the road; and that when he returned to the same position on the road in May, 1847, he found that during his absence the same brake had been put on four more cars; and that within a year and a half thereafter he put them on *all* of the twenty passenger and three baggage cars on the road. (p. 276, q. 3 and 4, x-q. 26 to 36.)

Phillips, a carpenter, says the brake was put on the one car Van Voorhis speaks of, and also on half a dozen others, in June and July, 1845. (p. 281, q. 3, x-q. 15 and 16.)

Marshall, a track layer, says Van Voorhis attended to all the repairing of the cars on that road in 1845, and that the double brake was put on one of them in that year, and as fast as the others were repaired on them also. (p. 283, q. 3, 4, and 5.)

Ryder, formerly a conductor on the Long Island Road, says he knows the brake was put on its cars before 1847; but whether it was in 1845 or in 1846 he cannot say. (p. 301, q. 7.)

Farrell, a baggage-master on the road from 1843 to 1856, says the brake was put on his baggage car *in the shop* in 1845 or 1846. (p. 280, q. 3.)

Osman says he went on the road as brakeman in August, 1848, and continued as such till about 1861; and that when he began his labors two or three of the passenger cars had the same brake on. (p. 286.)

We will now consider the testimony for the appellee.

Leach was superintendent of the Long Island Road, and also had entire charge of its mechanical department, from 1844 till the last day of August, 1847; and he says positively that he knows of his own knowledge that there were no double-acting brakes in use on that road during that period. (p. 440, q. 7.) He shows that he gave the closest personal attention to the machinery of the road, and knew all that was being done therewith. He also shows that Van Voorhis was only a yard-master at Brooklyn, who did nothing more by way of repairs than to replace a lost bolt or releather a brake shoe, and that if any further necessity for repair came under his observation, Van Voorhis reported the fact to Leach, and the latter would cause it to be attended to at the *shop* at Jamaica, eleven miles away from Van Voorhis' *yard*. (p. 442, q. 18.) He also says that John Areson was foreman of car repairs during all the time of Leach's administration. (p. 442, q. 16 and 17.)

Areson says he was foreman of car repairs for the Long Island Road from 1840 till 1861, and says positively that there never was any double-acting brake applied on that road till he applied one of a peculiar form, unlike ours, in 1848. (p. 445, q. 8, 17.)

Frederickson says he was a blacksmith in the car shops of the road from 1845 till about 1861; that Mr. Areson put on his brake about the latter part of 1847 or 1848; (p. 447, q. 6 and 7;) that he often had to overhaul the trucks, and therefore had every opportunity to see the brakes; and that he is *positive* that Areson's brake was the first double-acting brake he ever saw. (p. 448, q. 16.)

Chapman says he worked at the Jamaica shop, under Areson, from 1846, for several years; that he had a hand in the repairing of almost every car that was repaired, (p. 446, q. 9,) and that he never saw a double brake till Areson put his on, after Leach left. (p. 446, q. 6, 7, 12.)

Mitchell says he began work for the road about 1845; that he first saw any double brake about 1848, (p. 450, q. 7 and 8,) and describes it as being Areson's brake; and that no double brakes could have been on the road prior to that without his seeing them. (p. 451, q. 15.)

Palmer was employed on the road from 1851 to 1860 in various capacities, from conductor to acting superintendent, and he says that when he went on the road all the brakes were single brakes, except two of Areson's brakes. (p. 511, q. 6.)

The witnesses for the appellant nearly all had the reckless mendacity to say that Van Voorhis, their leader, had charge of the car repairs on the road, when they must have known, as is fully explained in our testimony, that he was a mere yard-master, eleven miles away from the car shops.

It is now high time to put a period to the discussion of the Tyler car.

The counsel for the appellee, however, cannot leave the subject without remarking, that "CORRUPTION WINS NOT MORE THAN HONESTY."

ACCOUNTING.

QUESTION A. *Is it the infringer's saving or the patentee's license fee, that is the proper measure of the profits recoverable in this case?*

I speak of this as a *question*, not because it *is* such, but because the appellant's counsel *treats* it as one. A few quotations from the leading decisions of this court on the subject will suffice to show, that if it ever *was* a question, it is such no longer.

In Mowry *v.* Whitney, 14 Wall., 620, (1870,) Mr. Justice STRONG, delivering the unanimous opinion of the court, laid down a rule which has since become almost as celebrated in the Patent Law as the rule in Shelly's case became in common law. It is as follows:

"The question is, what advantage did the defendant derive from using the complainant's invention, over what he had in using other processes then open to the public, and adequate to enable him to obtain an equally beneficial result? The fruits of that advantage are his profits."

In Burdell *v.* Denig, 92 U. S., 720, (1874,) Mr. Justice MILLER, delivering the unanimous opinion of the court, announced the doctrine, that the profits recoverable, according to the rule in Mowry *v.* Whitney, are so recoverable, *not* because they are a measure of the complainant's damages, (which was also established as law in Seymour *v.* McCormick, 16 Howard, 489: 1857,) but on the ground that the infringer is the complainant's *trustee* while making those profits. Justice Miller says:

"In cases where profits are the proper measure, it is the profits which the *infringer* makes or ought to make which govern, not the profits which the *plaintiff* can show *he* might have made. Profits are not the primary or true criterion of damages for infringement in an action at law. That rule applies eminently and mainly to cases in equity, and is *based upon the idea* that the infringer shall be converted into a *trustee*, as to those profits, for the owner of the patent which he infringes."

In Birdsall *v.* Coolidge, 93 U. S., 68, (1876,) Mr. Justice CLIFFORD again elaborately explained and enforced the same doctrine of trusteeship.

Perhaps the learned counsel will say, as he did when arguing against the doctrine of trusteeship before Mr. Justice HARLAN, in September last, that the court did not mean what it said in Burdell *v.* Denig and Birdsall *v.* Coolidge, but was merely indulging in metaphorical *dicta*. In deciding the cases then under consideration, however, Mr. Justice HARLAN used the following language, in an oral opinion taken down by a stenographer:

"I am convinced that it is settled law, determined by the weight of authority, that, independent of those cases where the account may be had on the ground of the injunction, the jurisdiction is now entertained in the Chancery Court on the ground that the party violating the patent is a *trustee*, and holds whatever profits he has made in trust for the patentee."

In The City of Elizabeth *v.* The American Nicholson Pavement Company, (1878,) 97 U. S., Mr. Justice BRADLEY delivered the unanimous opinion of this court, saying: "It is clear that a patentee is entitled to recover the profits that have been actually realized from the use of his invention, although, from other causes, the general business of the defendant in which the invention is employed may not have resulted in profits; as, where it is shown that the use of his invenproduced a definite *saving*."

These decisions dispose of the thirteenth assignment of error, and of the argument intended to enforce it, which begins with the last paragraph of page 91 of the appellant's brief, and extends to the end of the learned counsel's argument.

QUESTION B. *Was it the single brake or the Springfield brake that the master should have adopted as the standard of comparison, when proceeding, as he did, to assess profits under the rule in Mowry* v. *Whitney?*

In arriving at his conclusions, the master adopted the single brake as the standard of comparison, rejecting the Springfield brake, which the respondent insisted was the true one for the purpose in view. To justify his report in this regard, the master says that it appeared to him, from the testimony, that "the Springfield brake was an unsuccessful, abandoned experiment, and not a perfected, practical invention, and that it is a defective brake, and not adapted to ordinary every-day use on passenger trains." (pp. 36, 37.) The first three exceptions bring this finding to the attention of the court, and insist that the master was wrong therein, because the facts upon which he based his conclusion are claimed to be disputed by forty-two witnesses named in the exceptions.

Our present inquiry, therefore, is as to whether or not the Springfield brake was the proper standard of comparison, within the meaning of the rule in Mowry *v.* Whitney. The appellant can find no fault with the master in this regard, unless it shows that the Springfield brake was a more beneficial brake than the single brake; and here the burden is on *it*, and not on us, to show the contrary, because the master's report must stand, unless shown by the respondent to be positively erroneous.

SPRINGFIELD BRAKE OF 1843.

This brake was contrived by Ephraim Harris, then foreman on the Western Railroad of Massachusetts, and put by him upon two "crate" cars thereon.

He did not even *intend* it to be a *double* brake,—*i. e.*, one applying all the shoes at the same time from either end of the car,—but merely as a *double connected* brake, so arranged, that if one connection gave way the other would thereupon operate as its substitute. (Harris' deposition, p. 87, line 14.)

The accident that gave rise to it (p. 86, q. 3) did not, however, occur again during the short time it was in use, (p. 88, q. 3,) and as, for the general purposes of a brake, it proved to be inferior to the single brake, (p. 87, line 29,) it was abandoned, and the single brake put upon the two crate cars in its stead. (p. 88, q. 6.)

The *reasons* why the Springfield brake could not operate as a *double* brake, are set forth in the deposition of the expert Cooper. (p. 107, q. 10.)

Two or three of the respondent's witnesses attempt to say that Harris is mistaken as to his own intention in contriving the brake, and pretend to think that it did apply all the brake shoes simultaneously from either end of the car. One of them says (p. 146, line 5) he *understands* such to be the case, and another says (p. 1039, line 11) that he never heard that such was *not* the case. Harris, who had every reason to *know* whereof he affirmed, must of course outweigh any number of witnesses of this sort.

The Springfield Brake of 1856.

Being well aware that the facts about the experiment of 1843 are as I have stated, the respondent proceeded to prove (Stebbins, p. 1049) that the Springfield brake was again used in 1856, on car number 2 of the Western Railroad, and on twenty-two or twenty-four so-called "line" cars running over the various roads between New York and Boston, via Hartford and Springfield.

Stebbins says that he never operated the brake himself, except in switching; that he called it a good brake when in order; that it was no more liable to get out of order than any other; that it was abandoned after running sixteen months on the "line" cars, and two or three years on car 22, and the single brake substituted on the latter; and that the brake in general use on the Western Road, from its beginning to 1862, was the single brake.

How significant is this statement of the respondent's own witness. It is alone ample proof that the Springfield brake is not better than the single, for it had its birth on this very road nineteen years before, and was well remembered by Eddy (who succeeded Harris as master mechanic) all the time, (Eddy's deposition, p. 1040,) but never was thought highly enough of to permanently take the place of the single brake on one solitary car on that road.

Inasmuch as Stebbins' deposition refers only to these "line" cars and to car 2, it is fair to suppose that the respondent intended to go into those matters fully enough to show the successful working of the Springfield brake on those cars. It appears, however, that the indefatigable Mr. Whipple, its agent, was never able to find anybody else who would say that the brake was a success in those years; for no corroborating testimony is to be found in the record.

The complainant, however, with his customary thoroughness, took the testimony of thirteen witnesses, who say that, as used on those "line" cars, the Springfield brake was not so efficient as the single brake. They are Moran, (p. 668, q.

20,) Harding, (p. 675, q. 10,) Fenner, (p. 671, q. 12, x-q. 32, 37,) Pierce, (p. 680, q. 7,) Parker, (p. 683, q. 10–13,) Witherbee, (p. 685, q. 14,) Wallace, (p. 730, q. 5,) Dade, (p. 759, q. 6,) Fuller, (p. 765, q. 7,) Rand, (p. 766, q. 9,) Blessing, (who also testifies to a serious accident caused by the brake: p. 768, q. 11–18,) Charts, (who also was present at the accident: p. 822, q. 8 to 9,) and Wadleigh, (who testifies to still another serious accident caused by the brake: p. 827, q. 8–17.) The complainant also took the testimony of the car inspectors at each end of the line, both of whom say that great pains were taken to keep the brake accurately adjusted. (See Rood's deposition, p. 829, q. 5; and Hutchings', p. 832, q. 6 to 16.) Stebbins also says that *he* adjusted them at Springfield. (p. 831, x-q. 2 to 4.) No statement can, therefore, be made that the brake failed on the "line" cars because it was not well cared for.

THE SPRINGFIELD BRAKE OF 1872.

Painfully aware that the history of the Springfield brake, in 1843 and 1856, would utterly fail to make it available as a standard of comparison on the accounting in this case, the respondent, in 1871–2, caused a series of experiments to be made with it on six different railroads in New England, hoping that with extraordinary *care* the brake could be made at least to *appear* to operate as a double brake. I will, however, show that none of these experiments proved it to be any better than the single brake.

The Boston and Lowell Experiment.

The brake was applied to four cars on that road in January, 1872, (p. 1060, q. 8,) and remained in use till just after a certain special trial of a week to which they were put. (p. 733, q. 42.) It appears, from respondent's witness, Blood, (p. 1064,) that those four cars were mixed on the same train with one or more having the Hodge brake, and that for six days he noted the time occupied in stopping the train at the various stations. The net result of those exact-looking columns of figures he says he then set down, is, that the time occupied in stopping the train varied from 25 to 120 seconds. No other fact of any sort of interest is proven by the respondent with regard to the Boston and Lowell experiment. That this fact is utterly inconsequential, appears from the following circumstances:

1st. It don't appear anywhere in this case that the single brake would not have stopped the train as quickly, with the same number of brakemen. 2d. It *does* appear, from the testimony of Flagg, a locomotive engineer of 18 years' experience, that the *maximum* time required to stop such a train with a good double brake is 30 seconds, (p. 739, q. 3,) that being quicker than any of the 192 stops made with the experimental train, save two, 3d. Blood subjects his fairness in timing these stops to grave suspicion, by saying that he merely took the time for his own information, not expecting to use it again, (p. 1065, q. 26,)—inasmuch as Brigham, another employee of the road, says (p. 732, q. 23 to 34) that special pains were taken to put a conductor and a depot master to braking on that occasion, on account of their former experience and well-known efficiency therein, and that it was understood that the trial was made for the express purpose of being proven.

The complainant, however, refrained not from removing even the *pretense* of proof that the Springfield brake operated well on that road, by taking the testimony of Copithorn, Hillock, and McAlister, the men who put on the brakes and tried to keep them adjusted, under Mr. Whipple's directions. All of these men say that, despite every effort, the brakes could not be made to work properly. McAlister says, (p. 748, q. 27,) "I think they are a very poor thing." Copithorn says (p. 834, q. 19 to 21) that the brakemen constantly complained that they would not hold the train, and that it was impossible to make them work on all the wheels alike. Hillock says (p. 843, q. 13) that the brakes held on *one* truck but not on the other; thus agreeing with our theory, that at best the Springfield brake operates only as a single brake on one end of the car.

The Providence and Worcester Experiment.

O. L. Smith testified, for the respondent, (p. 1094,) that the Springfield brake was put on a car of the above road, for trial, December 22, 1872, and taken off February 22, 1873. No attempt is made by the respondent to prove that it operated successfully, which is perhaps a sufficient indication that it did not. The complainant, however, took the testimony of four of the railroad employees, who say that the brake was an entire failure on that occasion, (see Gates, p. 648, q. 9; Crocker, p. 650, q. 9; Oliver A. Lockwood, p. 658, q. 4; Mowry, p. 665, q. 3,) and that it was precisely because of this failure that the use of it was discontinued. (See Gates, p. 649, q. 11.) Three of these same witnesses also testify that the Tanner brake, put on another car of the same road at the same time in an imperfect form, and afterwards put on more perfectly under Mr. Sayles' direction, worked exceedingly well. (See p. 649, q. 14; p. 650, q. 10 to 13; p. 665, q. 5.) With reference to the excellence of the Tanner brake as used at this time, two others speak who did not use the Springfield. They are Thomas (p. 657, q. 10) and Lynch (p. 655, q. 10 and 14.) The circumstances were very disagreeable to Mr. Whipple, as might well be supposed, and he gave vent to his views as to the fatal character of their meaning, in an interview with Charles H. Smith, the clerk of the master car builder of the road. (See p. 647, q. 4.) It seems, however, that his spirits afterwards partly revived; for we find that some weeks after he caused some contrivances, claimed to represent the Tanner, Hodge, and Springfield brakes, to be constructed, and attempted to show, by means of scales inserted at various points therein, the amount of force exerted on sundry of the rods. He had two witnesses present at these experiments, and afterwards took them both to Boston to swear to the result. One of them did so to his satisfaction; but the other, O. L. Smith, on being requested by him to change his notes of the experiment with the Springfield brake from 32 pounds to 24 pounds, and swear to the latter as the truth, declined to do so, notwithstanding Mr. Whipple told him that if he did not it would "knock" or "spoil" the experiment. (p. 837, q. 22.)

This tribunal will hardly look with favor upon such a method of manufacturing evidence as that which failed with Mr. Smith, however much it succeeded with Mr. Birney.

The Boston and Providence Experiment.

The Springfield brake was put on two cars of this road, under Mr. Whipple's direction, in the winter of 1872-73, (p. 1051, q. 8 to 10,) and two witnesses—one conductor (Lincoln) and one brakeman (Rogers)—were found to swear that it operated well. Lang, the car inspector, however, says that there were constant complaints about its *not* working well; (p. 724, q. 13;) and that Rogers himself, after his return from Springfield, where he swore they worked so excellently, came to him and requested them to be taken off, *inasmuch as there was no further use for them, the testimony having been taken.* (p. 729, x-q. 40, q. 33 to 38.) They were accordingly removed. (See Lang's deposition for respondent, p. 1166, q. 15. See, also, Lang's correction of *another* statement in this deposition, on p. 831.) The alacrity with which the Springfield brake was in every case dispensed with, immediately after the testimony to support its superiority was taken, is significant of the true character of the brake and of these experiments.

The Hartford, Providence and Fishkill Experiment.

The Springfield brake was applied to one car on this road in February, 1872, (p. 1098, q. 4,) and taken off the following July.

One deposition only is found in the record referring to this experiment, that of Perry, who admits he never saw the brake operated but on one occasion. (p. 1098, q. 12.) He says also that a Mr. Lewis, a brakeman, had more to do with it than anybody else; (q. 14;) and it appears from question 24, (p. 1100,)put to him by Mr. Whipple, that this Mr. Lewis' deposition had already been taken. As, however, it is not in the record, the conclusion is, that it did not suit Mr. Whipple, and was therefore suppressed by him.

There was, of course, no need for the complainant to rebut such evidence, and he did not take pains to do so.

The Connecticut River Railroad Experiment.

The Springfield brake was put on four cars of this road, and run in a certain local train known as "Sampson's train," for a few months in 1872—sometimes alone, and sometimes with a car with a Hodge, and at other times one with a Tanner brake in the same train. The respondent took the testimony of four witnesses—Hitchcock, Wright, McCormick, and Sampson—as to their opinion of the result. McCormick says that the Springfield is better than the Hodge, (p. 1092, x-q. 6,) and Hitchcock says the Hodge is better than the Stevens. (p. 1077, x-q. 1.) If these two witnesses are not in error, then the railroad companies throughout the United States *have* been in gross darkness for twenty years; for they have persisted in using the Hodge and Stevens brakes, though the Springfield brake was open to them all the time. Those of them that try the Springfield brake also show perverse folly in abandoning it at the very first opportunity.

None of the four, however, had any but the very loosest methods of comparing the efficiency of the brake with that of any other. The experiment, therefore, furnishes no evidence whatever that it operated any better than the single brake would have done under the same circumstances. Indeed, Hitchcock admits (p. 1080, x-q. 29 to 31) that "kinking" and "spiraling" *did* occur on those cars; and of course kinking and spiraling practically resolve the Springfield brake into the single brake.

He also admits a fact he carefully concealed till 153 questions had been put to him—that the Springfield brake had already been removed from three of the four cars it had been put on six months before. This inconsequential, contradictory, and absurd testimony was not dignified by the complainant with any rebuttal. It fell because of its own weight.

The Boston and Albany Experiment.

This was more elaborate than any of the others. Car 123 was fitted with a form of the Tanner brake, modified by connecting the rods G^2 and H^2 to the *ends* of the center lever, instead of at points half-way between the ends and the pin B, and without *increasing* the leverage in the truck to correspond with the *decrease* in the center lever. The result of such a change was of course to reduce the power applied to each wheel just one-half. Car 124 was fitted up with the Springfield brake. The two cars were put on the road about the same time, and run in the same train, with a view to seeing which brake wore the most iron from the brake shoes under the same circumstances. The result (shown, however, without much regard to the rules of evidence) made it appear that the Springfield brake wore away 81 pounds, and the modified Tanner 80 pounds of iron, in eight weeks of use. (p. 970, q. 60.) Great reliance is placed on this substantially uniform outcome, as the foundation for the argument that the Springfield brake is as efficient as the Tanner for the purpose of retarding a train. The fatal error in the experiment lies in the fact that the Tanner brake was so constructed for the purpose of the experiment as to have only one-half the power it is perfectly well able to exert without sliding wheels. It, indeed, had as much power as the Springfield had on the same trial; but one substantial difference between the two brakes consists in the very fact that the Tanner is capable of exerting *double* the power without sliding the wheels, that the Springfield can without sliding them.

All the experts on both sides agree that it is a scientific law that friction is proportionate in its power to the *pressure* with which surfaces are forced together, without regard either to the *extent* of those surfaces or the *velocity* with which they are moved over each other. This being true, it is certain that 4,000 pounds of pressure will create as much retardation of a car, when applied to four wheels of a car as to eight, *provided* none of the wheels cease revolving. It is, however, equally clear, that eight wheels under a car will *bear* an *aggregate* pressure, without ceasing to revolve, *twice* as great as four of those wheels can.

Now, apply these two facts to the experiment under review. Suppose that the amount of force applied to the windlass, in the case of both brakes, was 600 pounds, that being in fact about the average amount applied to a 16-inch wheel by a brakeman.

In the Tanner brake, as modified for this experiment, 300 pounds would be transmitted to the top of *each* truck lever, and 6,000 pounds to the eight wheels of the car. In the Springfield brake, the force transmitted to the top of *one* truck lever (on our theory, that the shoes of the other truck cannot come in contact with the wheels) would be 600 pounds; and the amount applied to the four wheels of that one truck would be 6,000 pounds. Now, as the latter amount of pressure is not enough to make any of the four wheels cease to revolve, it follows, from the law of mechanics above stated, that the same total friction is applied to the four wheels in the Springfield as to the eight in the Tanner, with the result of wearing away the same total amount of metal and exerting the same total retarding power on the car. If, however, the Tanner brake had not been modified for the purpose of this experiment, and 600 pounds had been applied to its windlass, 600 pounds instead of 300 would have reached the top of each truck lever, and 12,000 pounds instead of 6,000 been applied to the eight wheels of the car. The pressure on each wheel would have been the same as on each wheel of the one truck of the Springfield that had any pressure at all; but the *aggregate* pressure on the whole car would have been just twice as great, and, consequently, the retarding effect twice as great. No such doubling of aggregate pressure can, however, be practiced with the Springfield brake; for if it was, the wheels of its one retarded truck would be subjected to 12,000 pounds, causing part or all of them to slide, which would at once violate what all admit is the first principle of successful retardation of railroad cars. It clearly appears, therefore, that this very plausible experiment has no tendency whatever to prove that the Springfield brake is other or better in practical operation than the single brake.

We are indebted to the respondent for having made and proved an experiment on the Connecticut River Railroad that corroborates this explanation with singular exactness. Hitchcock testifies (p. 1075, q. 46) a trial was made in stopping a car having a modified Tanner brake, (*i. e.*, one with the power reduced one-half,) with the result of ascertaining that the car was retarded substantially to the same extent, whether all the power of the brakeman was applied to eight wheels or to four, the latter being done by unhooking one of the truck levers from the center lever. Stearns, (p. 1087, q. 3,) Clancy, (p. 1087, q. 2,) and Carrigan (p. 1088, q. 6 all corroborate Hitchcock. This experiment is evidently much relied upon as proof positive that the single brake is just as good as the double; and so, indeed, it is, if the *aggregate* amount of pressure needed on the whole of the car can be applied to four of them without sliding. In this experiment, the brakeman applied insufficient strength to slide even four wheels. If, however, as is the case in all practical railroading, it is necessary to apply the greatest possible *aggregate* amount of force to all the wheels of the car, it is obvious that the use of the Tanner brake results in a total pressure twice as great as the single, and is therefore twice as efficient as it.

There is an entire lack of agreement among the employees of the Boston and Albany Road as to the practical efficiency of the Springfield brake during this experimental use of it in 1872. Five of them—Braman, (p. 651, q. 9 to 13,) Wood, (p. 672, q. 14 to 16,) Gardner, (p. 690, q. 19 to 24,) O'Brien, (p. 699, q. 8,) and Churchill (p. 761, q. 5 and 6)—speak very disparagingly of it indeed; and one of the principal of the respondent's witnesses (Taylor, p. 1030, q. 34) says that "perhaps the company would not like to have him speak his mind about the brakes," and that if he did he might be discharged. This statement very significantly accounts for the conduct of the employees who undertake to say that, in their opinion, the Springfield brake is as efficient as the Hodge.

Nothing could be more absurd than these last statements; for it appears from the testimony of the respondent's own witness, F. D. Adams, that (p. 974, q. 111) the proportions of the Hodge brake are such, as used on the Boston and Albany Road, that an aggregate pressure of nearly 12,000 pounds is spread over its eight wheels when 600 pounds is applied to the windlass; whereas 800 pounds applied to the windlass of the Springfield results in a *confessedly unequal* application of only 8,000 pounds to its eight wheels,—or, as *we have proven*, to four of its wheels only. Moreover, the "spiraling" and "kinking" of chains which occurs in all brakes, but which does no harm in any save the Springfield and Millholland, was a defect which alone makes the Springfield brake incapable of acting as a double brake. (See Parker, p. 683, q. 12, 13, 15.)

It appears, at page 847 of the record, question 1, that the Springfield brakes on this road were *also* abandoned soon after the respondent's testimony with regard to them was taken, since which abandonment it will not be claimed, on the other side, that one solitary Springfield brake has been attempted to be used anywhere in the world.

The Tender Brake.

The thirteenth exception brings the "tender brake" to the attention of the court as an alleged proper standard of comparison. As, however, it is open to the same objection as the Springfield brake, it could not possibly work on a passenger car any *better* than it, and must therefore share the fate of the latter, as an attempted and fanciful means of cutting down the recovery in this case. It has never in the world been attempted to be used on a passenger car; and if it should be, it could not possibly be operated from both ends, and no more efficiently from one end than the Springfield from either. It is true, it has been used over thirty years on tenders; but thirty thousand years of such use could have no tendency to adapt it to the totally different conditions of a passenger car.

QUESTION C. *How much did the defendant save on brakemen's wages, by means of the use of our invention, during the time sued upon?*

The master reported that the defendant was enabled, by the use of our patent, to dispense with the services of twenty brakemen, whom he finds it would have been obliged to employ if it had used the single brake on its passenger and other double-brake cars during the five years in which the infringement took place. He reports the resulting saving to amount to $41,280.

The fourth exception dissents from this finding, on the ground that the master therein *assumed*, that with the single brake the defendant would have been compelled to employ *double* the number of brakemen and baggagemen, in the management of its trains, that it did employ with the double brake.

The ninth assignment of error raises the same objection; and the eighth alleges that the court erred in finding *any* saving of brakemen.

Candor compels the appellee to admit that the *ninth* assignment is well founded, but he insists that the *eighth* cannot be sustained.

We admit that the master erred in finding a saving of two brakemen on the "mixed train" of the defendant, because it does not appear that with the single brake the conductor would not have been able, and would not have been called upon, to operate one of the additional windlasses that in such a case would have been required to be actuated; nor that the freight car brakemen could not, without interfering with their duties on the freight cars which composed part of the train, have actuated the other.

We also admit that the master erred in finding a saving of two brakemen on the "caboose cars" of the defendant, because it does not appear in the record that with the single brake the conductor would not have been able, and called upon to actuate the additional windlass required in that case to be operated, and because it does not appear that the defendant's freight-car brakemen were not sufficient in number to actuate two single brakes on the caboose cars, without interfering with their duties on the freight cars themselves.

We are compelled further to admit that the master erred in finding a saving of 16 brakemen on the four passenger trains of the defendant, because it appears that they *actually employed* 16 such men, and that with the *single* brake they would have required only 28, and not 32, as the master found. It follows, therefore, when the record is critically scanned, that the master should have reported a saving of 12 brakemen, instead of 20; and a saving of brakemen's wages of $24,768, instead of $41,280.

The testimony upon which his report is based was taken prior to 1873, when the rule in Mowry *v.* Whitney was yet new, and unapplied to any large variety of cases. The report is founded on certain theories of saving which seemed to be very strong at the time the report was made, but which subsequent decisions of the courts have determined to be rather too speculative to furnish the foundation of money decrees.

We therefore frankly admit, that, in the light of the law as it now is, the record furnishes no sufficient foundation for any decree on account of the saving of brakemen's wages greater than $24,768. That it does furnish an ample and strict foundation for *that* amount, we will now proceed to show.

First. It is stipulated, on page 849, that from June 2, 1859, until June 2, 1864, the defendant used the double brake on all the cars of four passenger trains per day, which trains had six cars each, on an average.

Second. It is stipulated, on page 850, that during this time the defendant employed 12 regular brakemen, besides the baggagemen, (which last appear from the other stipulation to be four in number,) who also acted as brakemen, making 4 such men on each train, or 16 in all.

Third. It is evident that each of these four sets of men were sufficient, with the *double brake*, to apply the brakes to all the wheels of the train upon which they were employed, with one to *spare*. It is possible this extra man *might* have been dispensed with, in which case the saving derived from our brake would have been increased; but as he was *not* dispensed with, we are not entitled to any recovery on that account.

Fourth. Thomas Hull, the master of the defendant's car department, and the defendant's own witness, says, (p. 959, x-q. 1,) "I consider it necessary to apply the brakes to all the wheels of a passenger train when stopping at stations, or in case of obstructions on the track, or in case of accidents to the train, for the safety of the passengers and train." Dunlap, the superintendent of the defendant's road during the time of the infringement, and who was also called by the defendant, says, (p. 964, x-q. 3,) "I did not employ more brakemen on the passenger trains during that period than I considered necessary for the safety of the trains and passengers."

It follows, from these two depositions, that the defendant was compelled by *the necessity of the case* to apply the brakes to all the wheels of its cars, on its passenger trains, with *at least* that degree of simultaneousness which three brakemen with the double brake can exert.

Fifth. That the defendant would have been compelled by the *same necessity* to employ 7 men to operate the brakes on each of its passenger trains, if it had used the *single* brake thereon, is very obvious, and, moreover, is sworn to by the defendant's own witness, Hull. (p. 960, x-q. 3.)

It positively follows, from the foregoing five points, that whereas with the double brake the defendant neither employed nor needed to employ more than 4 men to operate the brakes on each of its four passenger trains, or 16 in all, it would have been *compelled* to employ at least 7 men for that purpose, or 28 in all, if it had used the single brake thereon.

A clear saving of 12 brakemen's wages is thus *proven, by the strictest rules of evidence of which the nature of the case admits*, to have been constantly derived by the defendant from the use of our patent during the five years covered by the infringement.

It being stipulated, on page 849, that the defendant paid its brakemen an average of $34.40 per month during the period of the infringement, a short calculation will show that the aggregate saving during the five years was $24,768. Thus: $34.40 × 12 (the number of brakemen) = $412.80; and × 12 (the months in a year) = $4,953.60; and × 5 (the number of years) = $24,768. Or the same result may be arrived at from the master's report, thus: 20 : $41,280 : : 12 : $24,768.

Most of the appellant's objections to the master's report, as to saving of brakemen's wages, apply only to its *excess* over a saving of the wages of 12 such men. As far as its objections apply to a saving of *that* number, we will now proceed to show that they are not tenable.

First. It is not *true* that the defendant continued to use precisely the same number of brakemen on its passenger trains, with the double, as it formerly did with the single brake, for the simple reason that *it never used the single brake on its passenger trains at all.* The language the learned counsel puts into the mouth of Garvin cannot possibly be deduced from his deposition. Garvin says that the defendant used both the single and double brakes, (p. 962, q. 3,) but he don't say it used ~~double~~ single brakes on its *passenger* trains; and if he did, the court would not accept it, for it is expressly stipulated, on page 849, that the defendant came into existence and commenced running cars June 2, 1859; and that from that time forth it used the double brakes on *all* of its passenger trains, to wit, on 36 eight-wheeled cars running in its passenger trains, including *all* its passenger, baggage, and express cars.

Mr. Payson's statement, near the bottom of page 85, that this stipulation refers only to a small part of the defendant's road, is an entire error. The whole of the defendant's road, as it existed prior to June 2, 1864, was included in the suit. The other parts of the present road of the defendant were acquired June 2, 1864; (p. 850, line 3;) but it will not be pretended that the defendant has used single brakes on passenger cars since then.

Mr. Payson is *literally* right in saying that Garvin's is the only *evidence* on the subject. The stipulation, however, was made for the express purpose of dispensing with evidence, and cannot be disregarded in a fair review of the record. That part of the argument beginning near the bottom of page 82 and ending with line 13 of page 84, is all based on this error of fact.

The allusion therein to the experiments of November, 1871, has been heretofore shown to be fallacious; but we again call attention to the fact, that in that experiment the Tanner brake was deprived of half its leverage, so that it was capable of applying no more aggregate pressure to 8 wheels than the single did to 4, and as this amount was not sufficient to cause any even of the 4 wheels to slide, its retarding force was no greater when spread over 8 wheels, in accordance with the well-known and frequently sworn to law of friction, to wit: that friction is proportioned to aggregate pressure, and not to extent of surfaces in contact. If the Tanner brake had been given the total leverage represented in the patent, it would, without sliding any wheels, have applied double the pressure it did; and would, therefore, have stopped the train much sooner for that reason.

Second. The learned counsel seeks to rebut our positive proof that the defendant found it necessary to have brakemen enough to apply the brakes to all the wheels of the cars in its passenger trains, by saying that no road ever *did* that thing when using the single brakes.

We are curious to know how the learned counsel found out this fact, which he so positively states. The record does not disclose it. It is *such* a negative proposition as cannot practically be proved or known. Instead of the sworn necessity being "a coinage of the patentee's own brain," the statement that there is no such necessity is a coinage of the brain of the learned counsel.

The *record*, however, discloses the fact that the appellant itself *proved* that on the Erie road, when the single brake was used, one brakeman *was* employed on each car, (p. 930, x-q. 3, 4,) which is exactly double the proportion of brakemen that Hull, the appellant's own employee and witness, says (p. 959, x-q. 2,) is now required on a train of six cars, which was the number used on the trains of the appellant. (Stipulation, p. 849.)

We admit, however, that railroads did not *generally employ brakemen enough*, while using the single brake, to apply all the brakes to the wheels of its cars, but that fact fails to make out the counsel's conclusion, for three reasons which *are* disclosed in the record:

1. Passenger trains ran at much greater speed since this infringement began, in 1859, than they did prior to the general introduction of double brakes, which was about 1852. (p. 962, x-q. 20; p. 964, q. 5.)
2. Much heavier passenger cars have been generally used during the last twenty years or more, than those used in single-brake days. (p. 937, q. 5, 6, and 10.)
3. Passenger trains were retarded in great part by reversing the engines in the days of single brakes, a practice which went out of vogue upon the introduction of double brakes, (p. 905, q. 8 and 14; p. 909, q. 9 and 13; p. 915, q. 8 and 11; p. 919, q. 8 and 10; p. 920, q. 7, 8, and 9; p. 928, q. 18 and 29,) and which did annually cost, in *injury to the engine of a train*, far more than enough to have employed the extra brakemen which we claim the single brake would have necessitated even on the light trains of those days, if the engines had not been reversed. (p. 918, q. 8; p. 905, q. 15; p. 923, q. 8; p. 926, q. 12; p. 916, q. 15; p. 917, q. 5; p. 919, q. 16; p. 922, q. 13; p. 925, q. 15.)

This interesting fact, about reversing engines, of which the court will find no hint in the appellant's brief, though it is sworn to in the record by perhaps twenty locomotive engineers, and disputed by nobody, very effectually disposes of the appellant's claim that it would not have employed the extra brakemen with the single brake, because it could not have *afforded* it. The truth is, it could not afford *not* to.

Third. The appellant says, (p. 86,) "But admit that the defendant never used the single brake, how is the appellee to tell how many brakemen they would have used with it?"

That is exactly the situation of affairs contemplated by the rule in Mowry *v.* Whitney, and the courts have succeeded many times, while proceeding under it, in answering such questions as that of the counsel.

The question in this case is, "How many additional brakemen would the defendant have been obliged to employ with the single brake, or do worse; *i. e.*, or suffer greater loss and expense on account of reversing its engines?" If anything can be positively proven by testimony, we have proven the number to be *at least twelve.*

Fourth. The *reason* why the air brake has not enabled the railroads to reduce the number of brakemen below the number used with the double brake, is the one the counsel partly gives, viz., that nearly or quite four men are needed on an average on a train anyhow—one as baggageman, and the others to take care of the fire and lights, call out the names of stations, assist passengers on and off the cars, and generally to help in running the train, in addition to actuating the brakes, which, even with the *air* brake, they are liable to be called upon any moment to do, by reason of the breaking or bursting of a rubber connecting tube, which, whenever it occurs, renders the air mechanism as helpless as a scuttled ship.

It is, however, not the men they *employed* that furnish the foundation for the saving we claim. On the contrary, it is the twelve extra men they did *not* employ and did not *need* for these purposes, but which they would have been obliged to employ, for the sole purpose of actuating brakes, if they had used the single brakes on their passenger trains, instead of using our patent, as they elected to do.

QUESTION D. *How much did the defendant save on wheels?*

Inasmuch as the defendant never used the single brake on passenger trains, we were compelled to go to other roads to ascertain how many sets of wheels were spotted in a year by sliding, when the single brake was used, that being the best evidence of which the nature of the case admitted. An analysis of the evidence in that regard will show the number to have been about three sets per car per year. When we went to the defendant's road to ascertain how many sets were used there with the *double* brake, it turned out that the number was substantially the *same*, as sworn to by Gunther, a car repairer on the defendant's road. (p. 860, q. 7.)

The master, however, seems to have thought the rule of recovery to be what the defendant *might* have saved,—not what he *did* save. He could, indeed, have fortified himself, to some extent, in this opinion, by quoting one or two chance expressions of this court, which seem to hint at such a doctrine, notwithstanding the point was decided the other way in the case of Livingston *v.* Woodworth, 15

Howard, 546, (1853,)—which was the first case that ever came before this tribunal in which money was sought to be recovered in *equity* for the infringement of a patent.

Whether excusable or otherwise, he made that error; and because several witnesses testified that on other roads, where the single and double brake had been used side by side, there was a saving of two sets of wheels per car per year in the use of the double brake, he concluded that the defendant *might* have saved the same amount, and so charged it up in his report.

The exceptions to the master's report which apply to this matter, are the *eighth, ninth, tenth, eleventh,* and *twelfth.* Inasmuch as neither Gunther's name nor testimony is mentioned therein,—as, according to law, it ought to have been,—it is fair to suppose that the master's attention was not called, by the respondent's then counsel, to its scope and effect. The learned counsel in this court has, however, presented it in his argument with irresistible power. We know of no answer to be made to his reasoning on that point.

It appears, therefore, that the decree, as it came from the circuit, cannot be affirmed in its entire amount. In such cases, we understand that the form of the order is not to be fixed by this court, in pursuance of any rigid rule, but only as justice and convenience may seem to require. We therefore ask, that the court below be directed to enter a decree, and issue an execution, for a *specific sum.* If the case were sent back to the master to make any calculations, no matter how simple, his report would doubtless be excepted to on the other side, and the decree of the court below affirming it appealed from, so that, five years hence, the parties would be again before this court, with precisely the same case that has already sufficiently taxed the time of your Honors.

MISCELLANIES.

This brief has thus far discussed all of the questions in the case (save infringement) that seem to be capable of reduction into any symmetrical order.

The seventh assignment of error, and the fifth, sixth, and seventh exceptions to the master's report, are, however, yet undisposed of.

The three exceptions to the report are merely three ways of stating one point, viz.: "The master erred because he allowed to the complainant all the saving accruing to the defendant from its use of to the infringing brake, ignoring its alleged superiority over the brake of the complainant."

This exact point was decided by this court at the last term, in the case of The City of Elizabeth *v.* The American Nicholson Pavement Company.

Mr. Justice Bradley, in delivering the opinion, said:

"The next assignment of error is based on the hypothesis that the profits received by the defendant were not the fruits of the use of Nicholson's invention, appears to us to be destitute of foundation. The Nicholson pavement was a complete thing, consisting of a certain combination of elements. The defendants used it. If they superadded to it the addition made to it by Brocklebank and Trainor, they failed to show that such addition contributed to the *profits realized.* The burden of proof was on them to do this."

Our case is identical with that. If the Stevens brake *is* an improvement on the Tanner, and if such improvement *has any relation to the saving of brakemen's labor*, it was incumbent on the respondent to prove both those facts; but to do so, it made no attempt.

The seventh assignment of error is in these words: "The court erred in directing the master to assess *damages* in addition to profits."

The argument the learned counsel bases on this assignment, is to be found set down as his first objection to the *final* decree. (p. 81.) As the error, if it was one, pertains wholly to the *interlocutory* decree, and as the attention of the court below was never called to it till several years after the interlocutory decree was entered, and several weeks after the master's report was confirmed by a final decree, and then only in a petition for a rehearing, (p. 45,) from the decision upon which no appeal lies, and especially as the petition itself was improperly inserted in this record, it seems to be rather remarkable that the learned counsel should present the point to your honors in his argument.

The appellee will, however, adhere to his rule, not to rest any part of this case on a *technical* foundation, and will show that no error was in fact committed. He must, however, be permitted to remark, in passing, that the incident discloses the spirit that has guided the councils of the appellant from the beginning of this suit, seventeen weary years ago. A case that is probably embodied in a larger record than most of the present occupants of the bench have ever seen brought before it; a case in which there have been four protracted arguments in the court below; a case the record of which is composed of three hundred and forty-six depositions, besides voluminous pleadings and documentary evidence; a case that involves in it all the property of an American citizen; a case that has been brought to this court as a *test* case, to determine the validity of a patent, is gravely sought to be reversed and undone, because of a harmless slip of the pen in an interlocutory decree, which was not discovered even by the appellant's counsel till more than two years after it occurred.

That decree was drawn more than a year after the passage of the act of 1870, which in terms prescribed precisely the form of decree at which the seventh assignment of error is aimed.

The counsel who drew it, however, does not seem to have realized that the case had come down to him from a former generation; and that therefore it would be claimed that the decree must conform to the law as it existed prior to 1870. It is a fact, however, that a *final decree for damages*, and an *interlocutory decree* directing a master to *assess* damages, are two very different decrees. Even where the law of 1870 is applicable, the final decree for damages by no means necessarily follows even an unexceptionable master's report that damages were proved.

In Birdsall *v.* Coolidge, 93 U. S., 68, (1876,) the law of 1870 was construed by this court to mean, *not* that the complainant is entitled to recover in equity *both* profits and damages, but only that he may have in *chancery* whichever is the *larger* of the two. This constrnction, though perhaps not very clearly suggested by the *text* of the statute, is seen, by those most familiar with the complicated and peculiar circumstances of patent litigation, to be *perfectly* just.

The decision in Birdsall *v.* Coolidge, however, has not in the least obviated the necessity for the master being directed by the interlocutory decree to *assess* both damages *and* profits; because the court cannot be informed which *is* the larger without such an assessment. The learned counsel for the appellant, however, if he carries his seventh assignment of error to its logical conclusion, will some day be seen in this court endeavoring to secure the reversal of a decree because the court below directed the master to *assess* both damages and profits; notwithstanding the decision of the Supreme Court that the complainant cannot *have* both.

If the distinguished judge who decided this case below had given us a *final* decree in money for both profits and damages, he would, indeed, have entirely mistaken and misapplied the law, whether he was proceeding under the statute of 1870, or under the law as it existed prior thereto. An *interlocutory* decree, however, which merely directed the master to *assess* both, for the *information of the court*, though not as necessary, is as harmless in the one case as in the other.

I sincerely thank your Honors for waiving the rule in my behalf, and permitting me to explain this case to the court.

ALBERT H. WALKER,
FOR THE APPELLEE.

APPENDIX.

Sixty Millions of Dollars!!

Under this startling title, the learned counsel for the appellant discusses enormous sums of money, with an ease and freedom quite overcoming to the appellee, who has always been a man of very moderate means. The argument of the learned counsel seems to be, that the infringers should not be made to pay the appellee *anything*, because they owe him so *much*.

The point is not of that *legal* character contemplated by the rules as being discussible in a Supreme Court brief, and we therefore reply to it in an *appendix*, solely for the perusal of the curious.

We will here explain what the *real* magnitude of the appellee's claims against infringers will be in the event that this court decides in his favor all the issues he has caused to be argued in the foregoing brief. And here we will not base our calculation *wholly* on assertion, as the appellant's counsel does his. We will go to the record for its foundation,—to an affidavit of the president of the defendant corporation, found on page 47.

Mr. Keep, the president, states the average number of passenger cars running on the railroads of the United States during the first fourteen years of our patent to have been 4,500, and during the last seven years 9,000, which equals an average of 6,000 for the whole twenty-one years. In the face of this affidavit from his own client, the counsel *states* the average to have been 10,000.

The counsel then says, without any authority whatever, that the freight cars on which the double brakes are used are at least equal in number to the others, and that there are 3,000 of them on one road alone. Now, it is a generally known fact, among persons conversant with such matters, that the Pennsylvania Railroad is the only one in the country that uses double brakes on freight cars to any extent, and that it is very doubtful whether that road derives any particular profit from the particular form of double brake it uses, which is unlike any now before the court. Moreover, that company recognized our claims, and purchased a license in 1855. As to *horse* cars, fairness should have prompted the statement from the counsel, that nearly all their owners in the whole country have already paid us for the right to use our patent.

The decree, as it comes here from the court below, is for $47,725, and covers 38 cars for five years, equal to 190 cars for one year, or $251.18 per car per year, and amounting to $31,647,420, instead of $60,000,000, as the *theoretical* amount due the appellee, *if* all those cars had the double brake *all* the twenty-one years, and *if* the owners thereof used the brake as profitably as the decree would indicate the present defendant did, and *if* none of them had ever paid for licenses under our patent. At the outset of his statement, therefore, the counsel is shown by the record to have nearly doubled the facts, presumably because "sixty millions of dollars" is a rounder expression, rhetorically, than "thirty millions."

Moreover, nearly all the large roads then in the country purchased the right to use our patent from Mr. Tanner prior to his assignments to the appellee, in 1854 and 1859. Some of the licenses he gave are printed on 48, 49, and 50 of the record; and all that he gave, together with the licenses and releases afterward given by the appellee, cover more than half of all the use that has been had of our patent in the United States.

This consideration reduces the sum about which we are inquiring down to $15,000,000. This amount, however, lies almost wholly against the poorest of the infringers, and, judging from the reports of insolvencies in Poor's Railroad Manual for the last five years, at least two-thirds of the companies will never be able to respond to an execution for an unsecured debt like that owing to us. This reduces the sum to $5,000,000.

Furthermore, Mr. Justice HARLAN, a few weeks ago, decided in three of our cases, that the National Statute of Limitation of July, 1870, long ago cut off our rights of action under the *first* term of our patent, which will, if sustained by this court, reduce the amount about two-fifths more, leaving $3,000,000. We have also seen that the present decree is nearly twice as large as the evidence sustains in the now-understood state of the law, thus reducing the total *theoretical* value of the appellee's rights of action to $1,500,000, instead of the $60,000,000 the appellant so flamingly announces. This sum, however, will by no means be *collected* as a result of this court giving us such a decision as that for which we ask; because the counsel strenuously insists, that, on account of the accidental lack of the right to an injunction, equity has no jurisdiction to give us the infringer's profits at all, and that we can get nothing hereafter but such a license fee ($2,000) as we offered to take from this very defendant just before this suit was brought, seventeen years ago. That license fee would, if recovered now, give the appellant $117.64 per annum for lawyers' fees, and other expenses, while prosecuting this litigation. License fees, when paid amicably, are always cheerfully accepted by patentees; but it is *very* rare that, when collected at the end of a suit, (which in patent law is interminable,) they amount to enough to pay the expense of collecting them. If nothing but a *license fee* could be recovered in court for the infringement of a patent, infringers could infringe with impunity, for they would seldom be sued in these latter days.

The counsel also insists, in cases pending on the Circuit, that the extended term of our patent was invalid for two reasons wholly outside of any questions presented in this record. So far, therefore, from being a subject of envy, the appellee deserves sympathy and applause, for having devoted twenty-five of the best years of his life to testing the question as to whether our laws are strong enough to compel the combined railroad companies of the United States to pay over to inventors and patentees any portion of the money they have derived from pirating their property.
